Stem woody perennial, ſhort, irregular. Branches oppoſite, exactly four-ſided, rough. The height of the whole plant is from two to four feet. Leaves oppoſite, petioled, cordate, ſerrate, covered with ſtiff-hooked hairs, from one to three inches long, and from one to two broad. Petiole channelled, rough. Raceme terminating, or in the cleft of the exterior branchlets, erect, very long, rachis four-ſided, rough. Bractes ſolitary, one-flowered. Flowers towards the bottom of the raceme, remote; above approximated, ſmall, white.

Found by Dr. Roxburgh only in the vicinity of Samulcottah, on the terraces of old walls of pagodas. It flowers during the wet and cold ſeaſons, and while young it is a fair looking plant. The Telingas call it Obeera [i].

DESCRIPTION, *&c.*

[This is an upright ſhrub, three feet high. Branches round, ſomewhat aſh-coloured, appearing to be compoſed of ſhort joints from the fallen leaves, becauſe the leaves together with the ſtipules take their riſe from a common ſheath, which ſurrounds the branch and is permanent. The leaves are in threes, and very much reſemble thoſe of Roſemary. Stipules ſmall, acute and blackiſh, alternate with the leaves. Common peduncles axillary and only half the length of

[a] Hort. Kew. [b] Idem. [c] Willdenow. [d] Curt. magaz. [e] Willdenow. [f] Curtis.

[g] Roxburgh.

Digitized by Google

the leaves, ſuſtaining about five ſmall flowers, with white petals, and on ſhort peduncles. Berries ſoft and white, the ſize of a pea. The whole plant has an unpleaſant ſmell.—Native of Curaçao, on rocks by the coaſt [k].]

Mr. Miller ſays that he had it from Antigua, and that it grows naturally in many iſlands of the Weſt Indies. According to him it riſes to the height of four or five feet. He cultivated it before 1759.

PROPAGATION AND CULTURE.

It muſt be preſerved in the bark ſtove, and will not bear tranſplanting; ſeveral plants that were raiſed from ſeeds, thriving very well while they continued in the pot where they were ſown, but decaying when they were tranſplanted.

   S. lanceolata. *Retz. obſ.* 3. 26.
   Leaves ovate ſmooth, branches ſmooth wrinkled.

DESCRIPTIONS, *&c.*

1. This is a ſhrub with long rod-like branches, and four-cornered branchlets. Leaves oppoſite, naked, ciliate at the edge, a little patulous. Bractes ſimilar, but narrower. Flowers ſeſſile, ſolitary, long, coriaceous, red, ſilky-tomentoſe without. Calyx ciliate-bearded, coloured, length of the third part of the tube. Anthers white with brown tips in the throat [m].

According to Linneus, the ſtem is proliferous, with ſimple ſubvilloſe branches. Leaves acuminate, ſmooth, channelled. Flowers axillary, the length of the leaf, purpliſh on the outſide.

β. It varies with yellow flowers, in whitiſh membranaceous calyxes, and yellowiſh anthers dark yellow at the tips [n]. Alſo with longer and ſhorter leaves [o].

It is remarked by Mr. Dryander, that *Paſſerina ciliata*, as it ſtands in Reichard's edition of the Syſtema Plantarum, contains at leaſt three different plants. As there is no ſpecimen in Linneus's herbarium with this name, the plant which he meant can only be aſcertained by Clifford's herbarium, from which he originally deſcribed it. The paper there which repreſents Paſſerina 2. Hort. Cliff. has four Cape plants paſted on it; but that to which the deſcription in Hort. Cliff. applies, is *Struthiola virgata.* Linneus adds, that the ſynonyms which he has given are doubtful, on account of the imperfection in the figures and deſcriptions.—Among theſe doubtful ſynonyms is Sanamunda 1. Cluſii, on the authority of which Spain is given as the native place of this plant: this wrong ſynonym and falſe *locus natalis* have no doubt led the Spaniſh botaniſts to look for *Paſſerina ciliata* in their country. The ſpecimen in Sir Joſeph Banks's herbarium ſent from Spain by Profeſſor Ortega, under this name, has not properly ciliated leaves, but they are thinly covered with hairs. Whether Rauwolff's plant in Gronovii Flora Orientalis be the ſame as the Spaniſh plant, can only be determined by thoſe who have an opportunity of examining Rauwolff's herbarium at Leyden. Bergius's plant, from the deſcription is evidently different from either of thoſe above mentioned [p]. See *Paſſerina ciliata.*

2. The bractes in this are blue [q].

3. This is a ſmall ſhrub, ſmooth all over: branches ſlender, round; with four-cornered branchlets. Leaves like thoſe of Juniper and ſpreading. Flowers from the middle of the branchlets almoſt to the top, between the bractes, which are like the leaves, oppoſite and ſeſſile. Calyx ſmooth, length of the tube of the corolla. Corolla a little longer than the bracte, ſmooth and white, with ſharp ſegments. Stamens placed below the widened throat, ſo that the tips of the blackiſh-brown anthers do not reach the aperture of the throat.

4. This alſo is a ſmall ſhrub, ſmooth all over, with round branches, and four-cornered branchlets. Leaves oppoſite, imbricate as it were four ways, with the tips only ſpreading, ſomewhat wider than thoſe of Juniper. Flowers at the top of the branchlets, lateral, ſeſſile, ſolitary, within bractes ſimilar to the leaves but narrower. Calyx ſmooth, half the length of the tube. Corollas ſmooth, red on the outſide. Anthers in the throat, almoſt ſeſſile, cloſing the aperture with their apexes, brown, yellow on their inner ſurface where they pour out the pollen [r].

According to Linneus, the leaves are lanceolate-ſubulate, and ſmooth, as are alſo the ſtem and flowers. Cultivated by Mr. Miller in 1758. It flowers from june to auguſt [s].

5. Branches ſtiff, round, naked, with four-cornered branches. Leaves quite entire, acute, ſomewhat fleſhy or rather coriaceous, patulous. Flowers oppoſitely heaped at the tops of the branches, each ſeſſile within a bracte narrower than the leaves. Calyx pubeſcent, one-fourth of the length of the tube. Tube of the corolla long; border linear, both naked, rufeſcent. Colour and ſituation of the anthers as in the preceding ſpecies [t].

This and all the preceding are natives of that inexhauſtible magazine of ſhrubby plants, the ſouthern promontory of Africa. They may be increaſed by cuttings.

Leaves oppoſite ovate acute quintuple-nerved veined, cymes axillary.

DESCRIPTIONS, &c.

1. This is a middling ſized tree, with the trunk ſhort and crooked, but pretty thick, and the branches irregular: both are covered with a ſmooth aſh-coloured bark. Leaves oppoſite, on ſhort petioles, round-oval, ſhining, ſmooth on both ſides, entire, three-five-nerved, differing in ſize, from one and a half to four inches long, and from an inch to three inches broad. Stipules none. Flowers ſmall, greeniſh white, collected in ſmall terminating umbels. Calyx permanent. Filaments ſcarcely any or very ſhort, inſerted into the diviſions of the corolla. Anthers half within the tube and half out. Style length of the tube. Berry the ſize of a pretty large Apple, covered with a ſmooth ſomewhat hard ſhell, of a rich beautiful orange-colour when ripe, filled with a ſoft jelly-like pulp. Seeds from two to five, immerſed in the pulp [x].—They are thus deſcribed by Gærtner: orbicular, compreſſed-flat, or very ſlightly concavo-convex, but always ſwelling a little about the edge, and ſurrounded in the periphery itſelf with a narrow edge or a filiform annular ſtreak; in the middle on both ſides is a ſmall hole; they are of a whitiſh ſtraw-colour with a ſilky brightneſs intermixed: the umbilicus is a tubercle in the margin of the ſeed.

Native of the Eaſt Indies. Common in almoſt every part of the coaſt of Coromandel; flowering during the cold ſeaſon. The wood is hard and durable, and is uſed for many purpoſes by the natives. It is exceeding bitter, particularly that of the root, which is uſed to cure intermitting fevers, and the bites of venomous ſnakes, when that of Naga-muſadie cannot be had. The ſeeds are employed in the diſtillation of country ſpirits, to render them more intoxicating. The pulp of the fruit ſeems perfectly innocent, being eaten greedily by many ſorts of birds [x].

The ſeed of the fruit is the officinal nux vomica: it is about an inch broad, and near a quarter of an inch thick, gray, covered with a kind of woolly matter, and internally tough and hard like horn; to the taſte extremely bitter, but having no remarkable ſmell. It conſiſts chiefly of a gummy matter, which is moderately bitter; the reſinous part is very inconſiderable in quantity, but intenſely bitter; hence rectified ſpirit has been conſidered as its beſt menſtruum.

Nux vomica is reckoned amongſt the moſt powerful poiſons of the narcotic kind. It proves fatal to dogs in a very ſhort time. It has been found to poiſon hares, wolves, foxes, cats, rabbets, rats, and even ſome birds, as crows and ducks; and Loureiro relates that a horſe died within a quarter of an hour after taking an infuſion in wine of the ſeeds in an half roaſted ſtate. The effects appear to be rather uncertain, and not always in proportion to the quantity given. With ſome animals it produces the effects almoſt inſtantaneouſly; with others not till after ſeveral hours, when laborious reſpiration, followed by torpor, tremblings, coma, and convulſions, uſually precede the fatal ſpaſms or tetanus, with which this drug commonly extinguiſhes life.

From four caſes related of its mortal effects upon human ſubjects, we find that the ſymptoms correſponded nearly with thoſe which have been mentioned above of brutes; and diſſections both of the human ſubject and of dogs, not ſhowing any injury done to the ſtomach or inteſtines, prove that the Nux vomica acts upon the nervous ſyſtem, and deſtroys life by the virulence of its narcotic influence.

The quantity neceſſary to produce this effect upon a ſtrong dog, need not be more than a ſcruple. A rabbet has been killed by five, and a cat by four grains. Of the four perſons before alluded, one was a girl ten years of age, to whom fifteen grains were given in two doſes for the cure of an ague. Loſs however tells us, that he took one or two grains of it in ſubſtance, without diſcovering any bad effect; and that a friend of his ſwallowed a whole ſeed without injury.

In Britain, where phyſicians ſeem to obſerve the rule *ſaltem non nocere*, more ſtrictly than in many other countries, the Nux vomica has been rarely if ever employed as a medicine. On the Continent, and eſpecially in Germany, they have been guided more by the axiom, "what is incapable of doing much harm, is equally unable to do much good." The truth of this remark was fully exemplified by the practice of Baron Stoerck; and is farther illuſtrated by the medicinal character given of Nux vomica, which from the time of Geſner till that of a modern date, has been recommended by a ſucceſſion of authors, as an antidote to the plague, as a febrifuge, as a vermifuge, and as a remedy in mania, hypochondriaſis, hyſteria, rheumatiſm, gout, and canine madneſs.

In Sweden it has of late years been ſucceſsfully uſed in dyſentery; but Bergius, who tried its effects in this diſeaſe, ſays that it ſuppreſſed the flux for twelve hours, but that afterwards it returned again. A woman, who took a ſcruple of this drug night and morning, two ſucceſſive days, is ſaid to have been ſeized with convulſions and vertigo, notwithſtanding which the dyſenteric ſymptoms returned, and the diſorder was cured by other medicines; but a pain in the ſtomach, the effect of the Nux vomica, continued afterwards for a long time. Bergius therefore thinks it ſhould only be adminiſtered in the character of a tonic and anodyne in ſmall doſes (from five to ten grains) and not till after proper laxatives have been employed.

Loureiro recommends it as a valuable internal me-

[x] Roxburgh.

[x] Idem.

Digitized by Google

dicine in fluor albus, for which purpose he roasts it till it becomes perfectly black and friable, which renders its medicinal use safe without impairing its efficacy[y].

This plant was introduced in 1778, by Patrick Russel, M. D.[z]

There is a tree, but exceeding rare on the coast of Coromandel, which the Telingas call Naga Musadie. The leaves are opposite, short-petioled, obtuse, lanceolate, three-nerved, about two or two and a half inches long, by three quarters broad; the petioles connected at their insertions by a membrane, as in the natural order of Rubiaceæ. Hence it is probable that there is a species different from the Nux vomica tree, which yields the real Lignum Colubrinum. The wood of the root of this sort is esteemed by the Telinga physicians an infallible remedy for the bite of the Naga, (Cobra de Capella or Coluber Naja) as well as for that of every other venomous snake: it is applied externally, and at the same time given internally: it is also given in substance for the cure of intermitting fevers[a].

2. The Indian botanists contend that this is not a different species from the preceding[b]. The specimens sent by Koenig had ovate, three-nerved shining leaves: flowers in peduncled cymes at the end of the branches, even within, with a large peltate stigma[c].

Many different woods are sent to Europe under the name of Lignum colubrinum. Native of the East Indies.

3. This is a tree with opposite branches. Leaves very short, petioled, quite entire, smooth. Panicles at the upper joints of the branches, from four to six, in whorls, small, few-flowered, peduncled, simple. Pedicels interspersed with small awl-shaped bractes. Flowers small, nodding. Perianth five-toothed. Corolla funnel-form: border flat, five-parted, with the throat closed by long white villose hairs. Berry the size of a Cherry, dark red, one-seeded. Seed smooth. The flowers are very white, fragrant, pleasant and aromatic. The fruit at first tastes sweet, but afterwards bitter and astringent[d].

According to Retzius, the leaves are ovate-lanceolate, veined and darker. Flowers in sessile umbels by the sides of the branches, very hirsute within, extremely sweet when fresh, with a simple stigma[e].

Dr. Roxburgh remarks, that the leaves cannot be said to be five-nerved; that the stipules are entire and connecting; the panicles from the extremities of the last year's shoots, round the base of this year's, bearing a few small, erect, fragrant, greenish yellow flowers; the filaments rather longer than in Nux vomica; the berry shining, black when ripe.

From the circumstance of Roxburgh's plant not being five-nerved, Willdenow conjectures that it may be a new species; for the specimen sent him by Koenig had certainly five-nerved leaves, with the middle, and the two lateral ones on each side horizontally veined.

This grows to be a larger tree than the first species, and is much scarcer, being only found among mountains, and in woods of great extent. It flowers during the hot season. The wood is hard and durable, and used for various economical purposes. The pulp of the fruit, when ripe, is eaten by the natives, but the taste is rather disagreeable.

The ripe seeds are dried and sold in every market, to clear muddy water. Hence the English name of Clearing-nuts. The natives never drink clear well water, if they can get pond or river water, which is always more or less impure. One of the seeds is rubbed very hard for a minute or two round the inside of the vessel containing the water, which is generally an unglazed earthen one, and the water left to settle: in a very short time the impurities fall to the bottom, leaving the water clear, and perfectly wholesome. These nuts are constantly carried about by the more provident part of our officers and soldiers, in time of war, to enable them to purify their water: they are easier to be had than alum, and are probably less hurtful to the constitution[f].

Malachodendron. *Mitch. gen.* 16.

Flowers solitary, axillary, calyxes calyculate and lanceolate; styles distinct.]

DESCRIPTIONS, &c.

1. This shrub grows naturally in Virginia, where it rises with strong ligneous stalks, to the height of ten or twelve feet, sending out branches on every side covered with a brown bark, and garnished with oval spear-shaped leaves, about two inches and a half broad: they are sawed on the edges, are pretty much veined, and stand alternately: the flowers are produced from the wings of the stalk: they are white, with one of the segments of a yellowish tinge: it flowers in the latter end of may.

[2. This is described by Heritier as an elegant shrub rising to the height of about a fathom and half: the root is woody and branching: the stem erect, branched, and covered with a chinky ash-coloured bark: the branches are alternate, spreading, and not much bent; the young shoots of a reddish colour: the leaves are alternate, petioled, acuminate, laxly serrate, often revolute on the margin, slightly wrinkled, paler, and somewhat villose beneath. The flowers are axillary, solitary, scarcely peduncled, of a snow-white colour, tinged on the outside with a reddish and greenish cast: they are very sweet-scented, and consist of seven or eight unequal petals.

Native of Virginia: appears to have been formerly confounded by Linneus with the preceding species.]

PROPAGATION AND CULTURE.

Sow the seeds, which frequently fail when brought to England, either from not being properly impregnated, or duly ripened. When the plants come up, they are very difficult to maintain while young; for if they are exposed to too much sun, they will soon be

[f] Roxburgh.

destroyed,

Leaves oblong ſmooth on both ſides, peduncles axillary one-flowered ſolitary or two together.]

DESCRIPTIONS, &c.

1. The officinal Storax-tree riſes twelve or fourteen feet high: the trunk is covered with a ſmooth grayiſh bark, and ſends out many ſlender branches on every ſide. Leaves about two inches long, and an inch and half broad, of a bright green on their upper ſide, but hoary on their under; they are entire, and placed alternately on ſhort footſtalks. The flowers come out from the ſide of the branches, upon peduncles ſuſtaining five or ſix flowers in a bunch; they are white; and appear in june.

[In the Syſtema Vegetabilium it is remarked, that the germ is altogether ſuperior; that the natural number of ſtamens is ten; and that it is different from Haleſia.

The fruit is a juiceleſs drupe; of an ovate-globular form, terminated by the permanent ſtyle, pubeſcent with a hoary nap: rind thin, coriaceous: ſhell bony, brittle, box-coloured, before it is ripe conſtantly three-celled, but afterwards one-celled and valveleſs. Receptacle columnar, fungous, length of half the ſhell, accompanied by four or five egglets in each cell; but it is moſtly quite obliterated when ripe. Ripe ſeeds, three, two, or moſt frequently one only; thoſe variouſly angular, this ovate-globular, like an Almond, pale or ruſeſcent [g].

Native of Italy and the Levant. Cultivated in 1597, by Gerarde [h]; who ſays, I have two ſmall trees of it in my garden, the which I have recovered of ſeed.

Although the Storax-tree is indigenous to many of the ſouthern parts of Europe, yet the reſinous drug which it produces is only to be obtained in perfection from Aſiatic Turkey. The Storax iſſues in a liquid ſtate from inciſions made in the bark of the trunk or branches; and as it was formerly the cuſtom to collect this gum-reſin in reeds, it obtained the name of Styrax calamita. But the only kinds now to be found in the ſhops are the pure and the common Storax: the firſt is uſually in irregular compact maſſes, free from impurities, of a yelloviſh or reddiſh brown appearance, and interſperſed with whitiſh tears, ſomewhat like Gum Ammoniac or Benzoin; it is extremely fragrant, and upon the application of heat, readily melts. This has been called Storax in the lump, red Storax, and the ſeparate tears, Storax in the tear.

The common Storax is in large maſſes, very light, and bears no external reſemblance whatever to the former; but ſeems almoſt wholly compoſed of dirty ſawduſt merely caked together by the reſinous matter; and though much leſs eſteemed than the purer kind, yet we are told that when it is freed from the woody part it poſſeſſes more fragrance, and is ſuperior to the other. Rectified ſpirit, the common menſtruum of reſins, readily diſſolves the Storax, which may be inſpiſſated to a ſolid conſiſtence, as directed for the *Styracis purificatio* in the London Pharmacopœia, without ſuſtaining any conſiderable loſs of its ſenſible qualities.

Common Storax, infuſed in water, imparts to the menſtruum a gold yellow colour, ſome ſhare of its ſmell, and a ſlight balſamic taſte. It impregnates water conſiderably in diſtillation, and ſtrongly diffuſes its fragrance when heated, though it ſcarcely yields any eſſential oil. The ſpirituous ſolution, gently diſtilled off from the filtered reddiſh liquor, brings over with it very little of the fragrance, and the remaining reſin is more fragrant than the fineſt Storax in the tear. The pure reſin diſtilled without addition, yields along with an empyreumatic oil, a portion of ſaline matter, ſimilar to the flowers of Benzoin: ſometimes alſo a ſubſtance of the ſame nature may be extracted by boiling it in water.

Storax, with ſome of the ancients, was a familiar remedy as a reſolvent, and particularly uſed in catarrhal complaints, coughs, aſthmas, menſtrual obſtructions, &c. and from its affinity to the balſams it was alſo preſcribed in ulcerations of the lungs, and other ſtates of pulmonary conſumption. Our pharmacopœias formerly directed the *pilulæ e ſtyrace*; but this odoriferous drug has now no place in any of the officinal compounds; and though a medicine which might ſeem to promiſe ſome efficacy in nervous debilities, yet by modern practitioners it is almoſt totally diſregarded [i].

Old Gerarde ſays, of this gum there are made ſundry excellent perfumes, pomanders, ſweet waters, ſweet

[g] Gærtner. [h] Hort. kew. [i] Woodville and Lewis.

Digitized by Google

bags, ſweet waſhing balls, and divers others ſweet chains and bracelets.

2. Native of South Carolina, where it was obſerved by Mr. John Cree. Introduced in 1765. It flowers in june and july [k].

3. The Benzoin, or as it is corruptly called, the Benjamin tree, is of quick growth, and riſes to a conſiderable height: it ſends off many ſtrong round branches, which are covered with a tomentoſe or whitiſh downy bark. Leaves alternate, acuminate, veined, ſmooth above, tomentoſe beneath, a hand in length. Petioles round, ſtriated, channelled, tomentoſe, very ſhort. Flowers in axillary compound racemes or bunches, nearly the length of the leaves, and hanging moſtly to one ſide. The common peduncles are tomentoſe; the partial ones are alternate, ſpreading and tomentoſe; the pedicels are very ſhort. Calyx bell-ſhaped, very obſcurely five-toothed, tomentoſe on the outſide, more than a line in length. Petals five, perhaps connate at the baſe, linear, obtuſe, aſh-coloured on the outſide with a very fine nap, four times as long as the calyx. Filaments ten inſerted into the receptacle, a little ſhorter than the petals, united below into a cylinder the length of the calyx, above under the anthers ciliate. Anthers linear, faſtened longitudinally to the filaments, and ſhorter by half than them. Germ ſuperior, ovate, tomentoſe. Style filiform, longer than the ſtamens. Stigma ſimple.

The above deſcription was made from dried ſpecimens procured from Sumatra by Mr. Marſden, at the requeſt of Sir Joſeph Banks.

Though Garcias, Grim and Sylvius were acquainted with the real tree from which Benzoin is collected, their deſcriptions are ſo imperfect, that ſucceeding botaniſts have fallen into many errors concerning it; and it is remarkable that although this drug was always imported from the Eaſt Indies, moſt of the later writers on the Materia Medica have conceived it to be collected from a ſpecies of Laurus, native of Virginia, to which from this erroneous ſuppoſition, they have given the trivial name of Benzoin.

This error was firſt detected by Linneus, but he ſubſtituted another in its place; for in his ſecond Mantiſſa (p. 297.) he ſeems to think that the drug is furniſhed by a ſhrub which he there deſcribes under the name of Croton Bentzoe; and afterwards in the Supplementum Plantarum (p. 434.), he deſcribes the ſame plant again by the name of Terminalia Benzoin. Jacquin, who had been informed that this ſhrub was called by the French *Bienjoint*, ſuppoſes, with reaſon, that the ſimilar ſound of that word to *Benjoin*, which is the French name for Benzoin, or what we corruptly call Benjamin, may have occaſioned this miſtake.

Since that period Dr. Houttuyn has deſcribed the Benzoin Tree of Sumatra; but for want of good ſpecimens, has miſtaken the genus to which it belongs [l]. And thus it remained, till the year 1787, when Mr. Dryander firſt fully and publicly aſcertained it to be a Styrax.

This tree is deemed in Sumatra, which is its native country, to be of ſufficient age in ſix years, or when the trunk is about ſeven or eight inches in diameter, to afford the Benzoin: the bark is then cut through longitudinally, or ſomewhat obliquely, at the origin of the principal lower branches, from which the drug exudes in a liquid ſtate, and by expoſure to the ſun and air ſoon concretes, when it is ſcraped off from the bark with a knife or chiſſel. The quantity which one tree affords never exceeds three pounds; nor are the trees found to ſuſtain the effects of theſe annual inciſions longer than ten or twelve years. The Benzoin which iſſues firſt from the wounded bark is the pureſt, being ſoft, extremely fragrant, and very white; that which is leſs eſteemed, is of a browniſh colour, very hard, and mixed with various impurities. In Arabia, Perſia, and other parts of the Eaſt the coarſer ſort is conſumed in fumigating and perfuming the temples, and in deſtroying inſects.

The Benzoin which we find here in the ſhops is in large brittle maſſes, compoſed partly of white, partly of yellowiſh or light brown, and often alſo of darker coloured pieces: that which is cleareſt, and contains the moſt white matter, is accounted the beſt. This reſin has very little taſte, impreſſing on the palate only a ſlight ſweetneſs: its ſmell, eſpecially when rubbed or heated, is extremely fragrant and agreeable. It totally diſſolves in rectified ſpirit, the impurities excepted, into a deep yellowiſh-red liquor, and in this ſtate diſcovers a degree of warmth and pungency, as well as ſweetneſs. It imparts, by digeſtion, to water alſo a conſiderable ſhare of its fragrance, and a ſlight pungency: the filtered liquor, gently exhaled, leaves, not a reſinous or mucilaginous extract, but a cryſtalline matter, ſeemingly of a ſaline nature, amounting to one tenth, or one eighth, of the weight of the Benzoin. Expoſed to the fire in proper veſſels, it yields a quantity of a white ſaline concrete, called flores benzoes, of an acidulous taſte, and grateful odour, ſoluble in rectified ſpirit, and in water by the aſſiſtance of heat.

As the trees which afford Benzoin and Storax are congeners, and as their reſinous products are very ſimilar in their external appearances, and not widely different in their ſenſible qualities, it is reaſonable to ſuppoſe that they are analagous in their medicinal effects. Benzoin however, though rarely employed in a ſimple ſtate, has been frequently preſcribed as a pectoral, and is recommended for inveterate coughs, aſthmas, obſtructions of the lungs, and phthiſical complaints, unattended with much fever: it has alſo been uſed as a coſmetic, and in the way of fumigation for the reſolution of indolent tumours. Dr. Cullen, who claſſes Benzoin with the ſtimulants, ſays, that the flowers, which is the only preparation employed, are manifeſtly a ſaline ſubſtance of the acid kind, of conſiderable acrimony and ſtimulant power; it has been recommended as a pectoral; I have employed it in ſome aſthmatic caſes without finding it of uſe, and in a doſe of half a dram it appeared to be heating and hurtful. In the pharmacopœias the flowers are directed in the tinctura opii camphorata, and it is ordered in ſubſtance in the tinctura benzoes compoſita [m].

4. The leaves of this are toothed, in all the other ſpecies they are quite entire.—Native of South Carolina. Found by Mr. John Cree. Introduced in 1765. It flowers in june and july [n].]

PROPAGATION AND CULTURE.

1. It may be propagated by ſowing the ſeeds in pots filled with freſh light earth, and plunged into a moderate hot-bed. This ſhould be done as ſoon as poſſible when the ſeeds are procured, for if they are ſown the latter end of ſummer, and the pots kept in a moderate hot-bed of tanners bark all the winter, the plants will come up the ſucceeding ſpring; whereas thoſe ſown in the ſpring, often remain in the ground a whole year before the plants come up.

When the plants are come up, they ſhould be hardened gradually to the open air, into which they ſhould be removed in june, placing them in a ſheltered ſituation, obſerving to keep them clean from weeds, as alſo to ſupply them with water duly in dry weather. In this place they may remain till autumn, when they ſhould be placed under a common hot-bed frame, where they may be ſcreened from hard froſt in winter, but in mild weather enjoy the free air as much as poſſible, for if they are kept too cloſe their tops are very ſubject to grow mouldy. The leaves of theſe plants fall off in autumn, and in the ſpring, before they begin to ſhoot, they ſhould be ſhaken out of the pots, and their roots carefully parted, and each tranſplanted into a ſeparate ſmall pot filled with light freſh earth, and plunged into a very moderate hot-bed, obſerving to water and ſhade them until they have taken root; after which they ſhould be inured to the open air by degrees, into which they muſt be removed in june, placing them in a warm ſituation; where they may remain till the end of october, when they ſhould be removed into ſhelter for the winter ſeaſon. Theſe plants are tolerably hardy, and only require to be ſheltered from ſevere froſt while they are young; for in

[k] Hort. kew. [l] Dryander in Philoſ. tranſ. [m] Woodville. [n] Hort. kew.

Italy

Italy they grow extremely well in the open air, and produce fruit in great plenty. When the plants have grown three or four years in pots, and are become ſtrong, ſome of them may be turned out, and planted in the full ground, againſt a ſouth wall, to which their branches ſhould be trained in the ſame manner as fruit trees; and in this ſituation they will bear the cold of our ordinary winters very well; but in ſevere froſt, it will be proper to cover the branches with mats, ſtraw, or other light materials.

DESCRIPTION, *&c.*

The root is annual, and conſiſts of many long ſimple white fibres. Leaves all radical, ſmooth, awl-ſhaped with a recurved point. Stalk ſeldom more than two inches high, ſimple, ſmooth, bearing a ſimple ſpike of ſmall white flowers, always immerſed in the water, and ſo cloſed that the impregnation is accompliſhed in ſafety under the protection of the calyx and petals. Seeds ovate, compreſſed, about three on each ſide. By the firſt appearance of the flower and ſeed-veſſel this little plant might be taken for a Draba, but on examination an eſſential difference is found in the partition being contrary to the valves, not parallel with them, and yet thoſe valves are not keeled as in Lepidium, only concave; neither is the ſilicle notched, as in that genus. It is no leſs remarkable for its ſituation and mode of flowering under water, than for the peculiarity of its generic character[o].

Native of the northern parts of Europe. In the Britiſh dominions, Sherard firſt diſcovered it in the gravelly bottom of Lough Neagh, in Ireland. Since that, Dr. Hope found it in Lough Catran, and Mr. Stuart in Loch Tay, Scotland: and it has been ſeen in ſeveral lakes of North Wales; as near Llanberys, Llyn y Cwn and Ffynnon frêch near Snowdon and Llyn Aled in Denbighſhire. Dr. Dillenius and Mr. Brewer found it in moſt of the lakes under Snowdon. It flowers in july.

DESCRIPTION, *&c.*

[Stem ſhrubby, a fathom high, unarmed. Branches erect, ſubdivided, round, rugged, cicatriſed with the fallen leaves, glaucous, pubeſcent. Leaves cluſtered, in bundles towards the ends of the branchlets, erect, wedged, bluntiſh, ſhort, nerveleſs, veinleſs, thickiſh, villoſe-pubeſcent, pale green; on very ſhort petioles. Peduncles terminating and axillary, ſhorter than the leaves, from three to five-flowered. Flowers ſmall, yellow. Number of ſtamens always five[p]. According to Jacquin ten, but ſome of them often deficient, eſpecially the anthers; and both of them caducous, together with the corolla. He deſcribes it as an upright, elegant ſhrub, three feet high: the wood red and very hard; the flowers void of ſcent.—Swartz remarks, that in the ſpecimens from New Caledonia, ſome of the flowers had ten ſtamens.

Native of the ſea-coaſt of South America and the iſlands of the Weſt Indies. Browne ſays, that this little ſhrub is frequent by the ſea-ſide in the pariſh of St. James in Jamaica, that it ſeldom riſes above three or four feet, that the branches are pretty ſlender and flexile, and the leaves diſpoſed more thickly towards the tops.—Forſter marks it as found in Botany iſland.]

Mr. Miller deſcribes it as riſing, in the Weſt Indies, with a thick ſhrubby ſtalk eight or nine feet high, covered with a dark-brown bark: the leaves are about an inch long, and one eighth of an inch broad at the point, growing narrower to their baſe, of a dirty green colour. Peduncles about an inch long, each ſuſtaining two, three or four yellow flowers. Petals four or five. Seeds two, three, four or five. Theſe were brought from the Havanna by Dr. Houſtoun. Mr. Miller therefore muſt have cultivated it before the year 1733.

[o] Engl. Bot.

PROPAGATION AND CULTURE.

Sow the ſeeds on a hot-bed early in the ſpring; when the plants come up, weed them and refreſh them frequently with water. In warm weather raiſe the glaſſes to admit freſh air. When the plants are fit to remove, take them up carefully, and ſet each in a ſmall pot filled with freſh light earth, plunge them into the tan-pit, ſhading them until they have taken new root: after which water them duly every evening in hot weather, and admit freſh air in proportion to the warmth of the ſeaſon. In the winter theſe plants muſt be kept very warm, eſpecially whilſt they are young. They muſt alſo be frequently refreſhed with water, but it muſt not be given them in large quantities in cold weather. Theſe plants make ſlow progreſs the firſt year, but afterwards will grow pretty freely.

With pinnate leaves and winged common footſtalk.

DESCRIPTIONS, &c.

1. A ſhrub, with ſmooth branches, and ovate alternate leaves; cluſtered flowers, growing four, five, or ſix from each footſtalk.—Native of Trinidad.

2. This, ſays Willdenow, is ſo like the ſimplicifolia, that it is not eaſy to give an infallible criterion of the difference; except that the leaves are rather narrower.—Native of Trinidad.

3. A ſhrub of a ſmaller kind than the ſimplicifolia, with round and ſubpubeſcent branches: ovate-lanceolate, alternate leaves, and axillary flowers of four, five, or ſix, from each footſtalk.—Native of South America.

4. This is a middle-ſized tree, riſing to the height of eight feet or more, and branching towards the top: leaves alternate, and digitated, with three of the leaflets ſeſſile and annexed to the flat midrib: flowers corymboſe and axillary.—Native of the Caribbee iſlands.

5. Sufficiently diſtinguiſhed from the reſt by its pinnated leaves and round footſtalks.—Native of Trinidad.

6. This, according to Aublet, is a tree of twenty-five feet high or more, with a branchy top, and ſcattered ramulets: leaves alternate and unequally pinnate; of a bright green: flowers very ſmall.—Native of Guiana.

DESCRIPTIONS, *&c.*

1. This is a handſome plant, with a perennial root compoſed of long whitiſh fibres. Stem upright, ſimple, a foot high, ſlightly four-cornered, ſmooth, little leafy. Almoſt all the leaves radical, petioled, ovate or elliptic, quite entire, obſcurely nerved, ſmooth. Spike terminating, erect; with the peduncles oppoſite, erect, angular, one-flowered, bracted at the baſe. Bractes ſeſſile, elliptic-oblong, quite entire. Flowers cinereous-purple, of a dull colour, and void of ſcent. Segments of the calyx awl-ſhaped, ſpreading. Corolla ſpreading, with the ſegments elliptic, acute, dotted with black, and having nectariferous pores briſtly at the edge. Stamens awl-ſhaped. Anthers verſatile. Germ ovate, compreſſed. Style very ſhort, two-parted. The herb is very bitter [q].—Capſule ſurrounded with the permanent calyx and corolla, ovate-oblong, acuminate at both ends, and very ſhortly two-beaked above with the divaricating ſtigmas, compreſſed like a lens. Seeds numerous, ſuborbicular, leafy-compreſſed, with a wide membranaceous margin, ruſt-coloured, faſtened to the thickened edges of the valves in a double row: the radicle of the embryo is centripetal [r].

The old authors conſidered it as a Gentiana, and ſome more modern authors are of the ſame opinion: but Gærtner remarks, that whatſoever affinity there may be between theſe two genera, they cannot be united on account of the very different ſituation of the ſeeds and embryo.

Native of Germany, Auſtria, Switzerland, France and Siberia, in alpine bogs. It is a doubtful native of Britain. According to Hudſon, Richardſon found it in Wales. It flowers in auguſt.]

2. This has narrow linear leaves which come from the root, about three inches long, and half a quarter of an inch broad; the flower-ſtalks ariſe immediately from the root, are about ſix or ſeven inches high, and ſupport one blue flower.—Native of Virginia.

The flowers are white [s].

3. Stems filiform, branched at top, obſcurely angular, very ſmooth, as is the whole plant. Leaves ſeſſile, oppoſite, remote, a little united at the baſe, ſpreading very much, half an inch long. Peduncles in pairs from the top of the branches, filiform, having a linear leaflet at the baſe [t].—Native of Arabia Felix.

4. Root annual, ſhort, attenuated, cruciate with four lateral fibres, ſometimes branched a little with more, ſtiffiſh, white. The plant varies in ſize from a long ſpan and almoſt ſimple, to two feet, many-ſtemmed and more branched. Stem-leaves many, broad-lanceolate, withering as the ſtem grows up. Stem obſcurely four-cornered, ſingle or many, five or more, theſe laſt oppoſitely branched, ſtiffiſh, elongated, ſubfaſtigiate. Stem-leaves oppoſite, ovate-lanceolate, three-nerved. Peduncles axillary and terminating, filiform, naked, one-flowered. Flower nodding a little, for the moſt part four-cleft, but often five-cleft, of a pale greeniſh colour, ſomewhat four-cornered, bell-ſhaped, with the ſegments acute and converging, produced at the baſe into as many awl-ſhaped, ſpreading, ſtraightiſh horns as there are ſegments in the petal, of a greener colour; in alpine ſpecimens more elongated. Leaflets of the calyx linear, ſlender, of the ſame number as in the corolla. Anthers ſmall, within the corolla. Germ cylindric-conical. Capſule within the permanent corolla, cloſed, ſhaped like a ſilicle, two-valved. Seeds fewer, a little larger than thoſe of the poppy, browniſh gray.

Native of Siberia, where for its grateful bitterneſs, it is received among the domeſtic remedies of the inhabitants. It is common on both ſides the river Jeniſea, in ſandy moiſtiſh pine woods. It occurs in ſome parts of a lower ſtature, with larger ſeeds, and more turgid flowers. In Kamtſchatka it is ſcarcely more than two inches high, with a ſimple one-flowered ſtem, and two or three pairs of leaves only.—It is alſo found in Canada.

5. Root ſimple, drawing to a point, ſtouter than in the preceding, and ſeeming to be biennial. Plant very tender, ſoft, bright green, as in corniculata. Root-leaves ovate, five-nerved, elongated into the petiole. Stems from the root many, ſlender, red, often decumbent, in the adult plant very much branched, here and there in a manner dichotomous, producing abundance of flowers from all the axils on long and very ſlender pedicels. Stem-leaves ſubſeſſile, ovate-lanceolate, five-nerved. Flowers much ſmaller than thoſe of the preceding, greener but ſometimes a little reddiſh, four-cleft, ſubglobular bell-ſhaped, with the ſegments divided almoſt to the baſe, ovate, having two nectariferous yellow dots on the inſide of each. Calyx-leaves ovate-lanceolate. The plant is very ſmooth, as in the reſt of this genus.

Native of eaſtern Siberia: ſcarcely bitter. It flowers in auguſt: the preceding in july.

6. This is an annual plant, ſcarcely a ſpan high, with a ſimple, ſlender, attenuated root. Stem quite ſimple, erect, filiform, round, with four or five pairs of lanceolate, nerved leaves; the lower leaves are ovate-lanceolate. Petioles axillary, and ſome terminating, leafed, ſubfaſtigiate. Flowers ſmall, all four-cleft. Calyx-leaves linear. Segments of the corolla ſcarcely cohering at the baſe, ſpreading, deep blue with an orange-coloured ſcar in the middle notched at the edge, and viſible at the back. Stamens ruſeſcent, ſhorter than the corolla.—Native of Kamtſchatka [u].]

PROPAGATION AND CULTURE.

Theſe plants growing naturally in ſwamps, are with difficulty preſerved in gardens, and as they do not produce ſeeds in England, are only propagated by parting the roots; the beſt time for which is in ſeptember, that they may have time to be rooted before the froſts come on. They ſhould be planted in the ſhade, and have a looſe moiſt ſoil. In ſummer they muſt be frequently watered.

DESCRIPTIONS, &c.

1. The Mahogany is a lofty and very branching tree, with a wide handſome head. Leaves reclining, alternate, ſhining, eight inches long, numerous on the younger branches: leaflets for the moſt part four pairs, but often three, ſeldom five, without any odd one, falcate-lanceolate, quite entire, acuminate, bent in backwards, petioled, oppoſite, an inch and half long. Racemes ſubcorymbed, with about eight flowers in each, axillary, ſolitary, two inches long. Flowers ſmall, whitiſh[x]. Capſule large, (ſometimes attaining the ſize of a child's head,) woody, ovate, of a ſmoaky-rufeſcent colour (or ferruginous,) towards the top five-celled, but in other parts widely one-celled, five-valved. Valves thick, opening from the baſe, caducous, covered within by a thick flexile coriaceous lamina, exactly equal to them in ſize. Receptacle central, free, woody, five-cornered, from a narrower baſe widening much and thickening upwards, but narrowing again at the point, and on each ſide of the pyramid having a double row of very ſmall ſcars, into which the ſeeds are inſerted. Seeds numerous, collected into five bundles, imbricate downwards, compreſſed, yellowiſh-rufeſcent or cinnamon-coloured, having a nucleus below, but ending above in a long membranaceous wing[y].

Linnæus remarks that this tree has a great affinity with Cedrela (Barbadoes Cedar). They were joined by Miller and others under the name of Cedrus. Jacquin firſt ſeparated them: the Mahogany tree, according to him, having the flower of Melia, and the fruit of Cedrela opening from the baſe.]

The Mahogany tree is a native of the warmeſt parts of America, and grows plentifully in the iſlands of Cuba, Jamaica and Hiſpaniola; there are alſo many of the trees on the Bahama iſlands. In Cuba and Jamaica there are (or rather were) trees of a very large ſize, ſo as to cut into planks of ſix feet breadth. Thoſe on the Bahama iſlands are not ſo large; though theſe are frequently four feet diameter, and riſe to a great height, notwithſtanding they are generally found on the ſolid rock, where there ſeems to be ſcarcely any earth for their nouriſhment.

The wood which has been brought from the Bahama iſlands has uſually paſſed under the name of Madeira wood. The Spaniards make great uſe of this wood for building ſhips, and it is better adapted to this purpoſe than moſt ſorts of wood yet known, being very durable, reſiſting gun ſhots, and burying the ſhot without ſplintering: nor is the worm ſo apt to eat this wood as that of the oak; ſo that for the Weſt Indies, ſhips built of Mahogany are preferable to any other.

The excellency of this wood for all domeſtic purpoſes has been long known in England: and it is a matter of ſurprize that for a long time the only author who had noticed this tree was Mr. Cateſby.

Dr. Browne informs us that the Mahogany was formerly very common in Jamaica, and while it could be had in the low lands, and brought to market at an eaſy rate, furniſhed a very conſiderable branch of the exports from that iſland; that it thrives in moſt ſoils, and varies both in grain and texture with each; that which grows among rocks being ſmaller but very hard and weighty, of a cloſe grain and beautifully ſhaded; while the produce of the low and richer lands is obſerved to be more light and porous, of a paler colour and open grain. The tree grows very tall and ſtraight, and generally bears a great number of capſules; the flowers are of a reddiſh or ſaffron colour; and the fruit is about the ſize of a turkey's egg. The wood is a very ſtrong timber, and anſwers very well in beams, joiſts, plank, boards and ſhingles; and has been frequently put to thoſe uſes in Jamaica in former times.

2. This is a very large tree, with a ſtraight trunk, riſing to a great height and thickneſs, and covered with a gray, ſcabrous, cracked bark. Branches numerous; the lower ſpreading, the higher aſcending, forming a very large ſhady head. Leaves alternate, about the extremities of the branchlets, abruptly pinnate, about twelve inches long: leaflets oppoſite, very ſhort, petioled, three or four pairs, oval, obtuſe or emarginate, the lower ſide extending a little farther down on the petiolet than the upper ſide, ſmooth, ſhining, from three to five inches long, and from two to three broad, the lower ſmalleſt. Petiole round, ſmooth, about nine or ten inches long. Stipules none. Panicle very large, terminating, diffuſe, bearing great numbers of middle-ſized, white, inodorous flowers. Peduncles and pedicels round and ſmooth. Bractes very minute. Calyx inferior, five-leaved. Nectary not quite half the length of the petals, a little bellied; teeth at the mouth bifid. Filaments very ſhort, inſerted juſt within the mouth of the nectary. Germ conical: ſtyle thick, tapering: ſtigma large, targetted, ſhutting up the mouth of the nectary. Capſule ovate, large, five-celled, five-valved: valves gaping from the top. Receptacle in the centre, large, ſpongy, five-angled: angles ſharp, and connected with the ſutures of the capſule, between them deeply ſulcated. Seeds obliquely wedge-ſhaped, enlarged by a long membranaceous wing, inſerted at the upper point of the wing into a long brown ſpeck, on the upper part of the excavations of the receptacle: all the reſt of the receptacle is white.

Native of the mountainous parts of the Rajahmundry Circar, north of Samulcotah and Peddapore. It flowers about the end of the cold, or beginning of the

[x] Jacquin. [y] Gærtner.

Digitized by Google

the hot ſeaſon; and the ſeeds ripen in three or four months after.

The wood is of a dull red colour, remarkably hard and heavy; it is reckoned by the natives the moſt durable wood they know, and on that account is uſed for all the wood-work in their temples; it is alſo very ſerviceable for various other purpoſes.

The bark is internally of a light red colour: a decoction of it dyes brown of various ſhades, according as the cloth has been prepared. Its taſte is a bitter and aſtringent united, and very ſtrong, particularly the bitter, at the ſame time not any way naufeous or otherwiſe diſagreeable. Soymida is its name among the Telingas.

3. This is a middle-ſized tree, with the trunk tolerably erect; ſupporting a large ſpreading, evergreen, ſhady head: bark pretty ſmooth, of a dark ruſt-colour. Leaves about the extremities of the branches, abruptly pinnate, ſix or ſeven inches long: leaflets alternate, on ſhort petioles, from ten to twenty pairs, obliquely oval, obtuſe, upper half twice the breadth of the lower, ſmooth, entire, an inch long and three eighths of an inch broad. Petioles round, ſmooth. Stipules none. Panicles pretty large, terminating. Flowers numerous, ſmall, yellow. Bracte ſmall, below each ſubdiviſion of the panicle. Nectary a fleſhy notched ring ſurrounding the baſe of the germ. Germ ſuperior; ſtyle ſhort: ſtigma ſimple. Capſule about an inch long, and half an inch in diameter, oblong, three-celled, three-valved, opening from the apex. Seeds four in each cell, membrane-winged, placed alternately with four oblong, compreſſed, ſpongy bodies, reſembling the ſeeds themſelves.

Native of the mountainous parts of the Circars: flowering at the beginning of the hot ſeaſon.

The wood of this tree is of a deep yellow colour, remarkably cloſe-grained, heavy and durable: it is uſed for various economical purpoſes, and comes nearer to box-wood than any other in that country. It is the Billoo of the Telingas*.

PROPAGATION AND CULTURE.

1. In the Weſt Indies this tree grows to a large ſize in a few years. The manner of their propagation in the Bahama iſlands, as deſcribed by Mr. Cateſby, is as follows. When the fruit is ripe, the outer hard ſhell, ſeparates next the foot-ſtalk, and thereby expoſes the ſeeds; which being broad and light, are diſperſed on the ſurface of the rocks. Such of them as happen to fall into the fiſſures, very ſoon ſend forth roots, and if theſe tender fibres meet with reſiſtance from the hardneſs of the rock, they creep along the ſurface, and ſeek another fiſſure, into which they creep, and ſwell ſo as to break the rock, and thereby make way for the root to penetrate deeper.

It is propagated here by ſeeds, which may be eaſily procured from the Bahama iſlands, whence moſt of the good ſeeds which have come to England have been brought. Moſt of thoſe that have been ſent from Jamaica have not ſucceeded.

Sow the ſeeds in ſmall pots filled with light ſandy earth, and plunge them into a hot-bed of tanner's bark, giving them a gentle watering once a week; if the ſeeds are good, the plants will appear in a month or five weeks, and when they are two inches high, fill a ſufficient number of ſmall pots with light earth, and plunge them into the tan-bed a day or two, that the earth may be warmed before the plants are put into the pots; then ſhake out the young plants, carefully ſeparating them ſo as not to tear their roots, and plant each ſingly in the pots, ſhading them till they have taken freſh root: after which treat them in the ſame manner as directed for other plants from the Weſt Indies; being careful not to give them much water, eſpecially in winter; as alſo when they are ſhifted, to preſerve the earth about their roots.

Mahogany being now ſo generally uſed in England, it would ſurely be worth the attention of the planters in America, many of whom are poſſeſſed of barren

* Roxburgh.

rocky lands, which produce them no profit, but might turn to great advantage, if the ſeeds of this tree were to be ſown in them.

Lin. ſyſt. 610. *ſuppl.* 302.

DESCRIPTION, *&c.*

This is a tree with a thick ſofty trunk. Branchlets ſhorter, ſmooth, marked with ſcars from the fallen leaves. Leaves at the end of the branchlets, approximating, oblong, lanceolate, quite entire, very ſmooth, glaucous, keeled underneath with a blunt rachis: veins very fine, tranſverſe; conſiſtence of Bay leaves, a hand in length. Petioles very ſhort, half round. Umbel terminating, ſimple, few-flowered, ſeſſile. Peduncles erect, angular, one-flowered. Flowers the ſize of thoſe of Thea, red. Calyx ſhort, with blunt ſcales. Petals five, converging, like thoſe of Trollius, into an oblate ſpheroidal globe; each petal lying over the next with the right margin. Sheath of the ſtamens undivided, cloſely covering the piſtil, and ſtanding out beyond the flower, like a ſuperior calyx in the fruit. This undivided ſheath is terminated at the top by five ſeſſile Anthers, alternating with five ſtigmas, forming a ſort of ſtar. The coriaceous rind of the fruit covers the painted ſeeds, which have a deep-yellow mucous ſubſtance interpoſed between them. Theſe ſeeds are very grateful to Parrots.—Native of Surinam*.

SYMPHYTUM (*of Pliny.* Συμφυτον *of Dioſcorides:* απο του συμφυειν, *from its conglutinating quality.*)

Lin. gen. n. 185. *Reich. n.* 197. *Schreb. n.* 245. *Tournef. t.* 56. *Juſſ.* 131. *Gærtn. t.* 67.

Claſſ. 5. 1. Pentandria Monogynia.

Nat. order of *Aſperifoliæ. Borragineæ* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-parted, erect, five-cornered, acute, permanent.

COR. one-petalled, bell-ſhaped: *tube* very ſhort: *border* tubular-bellying, a little thicker than the tube: *mouth* five-toothed, obtuſe, reflexed: *throat* fenced by five lanceolate rays, ſpinuloſe at the edge, ſhorter than the border, converging into a cone.

STAM. *Filaments* five, awl-ſhaped, alternate with the rays of the throat. *Anthers* acute, erect, covered.

PIST. *Germs* four. *Style* filiform, length of the corolla. *Stigma* ſimple.

PER. none. *Calyx* larger, widened.

SEEDS four, gibbous, acuminate, converging at the tips.

ESSENTIAL CHARACTER.

Cor. border tubular-ventricoſe: throat cloſed by lanceolate rays.

SPECIES.

1. Symphytum officinale. *Common Comfrey.*

Leaves ovate ſemidecurrent: the uppermoſt oppoſite.

3. Symphytum orientale.

Lin. ſpec. 195. *Reich.* 1. 395. *Willd.* 1. 771.

S. orientale, folio ſubrotundo aſpero, flore cæruleo. *Tournef. cor.* 7.

S. conſtantinopolitanum, boraginis folio & facie, flore albo. *Tournef. cor.* 7. *Buxb. cent.* 5. 36. *t.* 68.

Leaves ovate ſubpetioled.

DESCRIPTIONS, *&c.*

1. Root perennial, fleſhy, externally black. Stem two or three feet high, upright, leafy, winged, branched at the top, clothed with ſhort briſtly hairs that point rather downward. Leaves waved, pointed, veiny, rough; the radical ones on footſtalks, and broader than the reſt. Cluſters of flowers in pairs on a common ſtalk, with an odd flower between them, recurved, denſe, hairy. Corolla yellowiſh-white, ſometimes purple, the rays downy at each edge[b].

Native of Europe and Siberia: frequent in watery places, on the banks of rivers and ditches; flowering from the end of may to ſeptember.

The root abounds in a pure taſteleſs mucilage, like that of Marſh-Mallow, but, according to Lewis, ſomewhat ſtronger bodied, or more tenacious, and in rather larger quantity. Being eaſily obtained, it may therefore be conveniently ſubſtituted for that of Althæa or Marſh-Mallow, in all caſes where emollients or demulcents are in uſe: as, in irritations of the throat, inteſtines, and above all the bladder[c].

β. The variety with a red or purple flower is more common on many parts of the continent than in England. In Holland I ſeldom obſerved any other. Dr. Sibthorpe made a new ſpecies of it, diſtinguiſhing it by a ſhorter and more ſpreading calyx; but he does not ſeem to be warranted in this remark[d].]

Mr. Miller aſſerts that the difference in colour is permanent in the plants raiſed from ſeeds, and that the purple and whitiſh yellow flowers are never found mixed, where the plant grows wild; but as he found no ſpecific differences between them, he has not ſeparated them.

2. Roots compoſed of many thick fleſhy knobs or tubers, which are joined by fleſhy fibres; the ſtalks riſe a foot and half high, and incline on one ſide; the leaves on the lower part are ſix inches long, and two inches and a half broad in the middle, ending in acute points, and not ſo rough and hairy as the preceding ſpecies; they are alternate and ſeſſile. The two upper leaves on every branch ſtand oppoſite, and juſt above them, are looſe bunches of pale yellow flowers, the corolla of which is ſtretched out farther beyond the calyx than in the common ſort.

[It is perhaps a variety of that, but the root is white on the outſide, not black as in the preceding[e]. It is alſo a lower plant. The ſtem-leaves are ovate, and the petioles winged, but they are ſcarcely decurrent. The rays of the corolla are toothletted, as in the officinale[f].

Native of Germany, Auſtria, France, Spain and Italy.—It has been obſerved in ſeveral places in Scotland. Mr. Yalden found it growing ſparingly oppoſite the new well at the water of Leith, but more plentifully in Dr. Robertſon's walks at North Marchiſton, near Edinburgh[g]. It was cultivated in 1596 by Gerarde, and flowers from may to october[h].]

3. Root perennial. Stalks two feet high. Leaves rounder, and armed with rough prickly hairs. Flowers in bunches like the firſt ſort, but blue. They appear in march, but ſeldom produce ſeeds in England. By the ſide of rivulets near Conſtantinople.

PROPAGATION AND CULTURE.

Theſe plants may be cultivated, either by ſowing their ſeeds in the ſpring, or by parting their roots; the latter being the more expeditious is chiefly practiſed. The beſt ſeaſon for parting the roots is the autumn, at which time almoſt every piece of a root will grow. They ſhould be planted about two feet and a half aſunder, that they may have room to ſpread, and will require no farther care but to keep them clear from weeds; for they are extremely hardy, and will grow upon almoſt any ſoil, or in any ſituation.

3. Symplocos Arechea.
   L'Herit. in Linn. tranſ. 1. 176.
   Peduncles about five-flowered, leaves ſerrate almoſt naked.
4. Symplocos octopetala.
   Swartz prodr. 109.
   Flowers eight-petalled.

DESCRIPTIONS, &c.

1. This is a branching tree, twenty-five feet high. Leaves ovate, acute, ſhining, ſubcoriaceous, petioled, placed indeterminately. Flowers white, ſmelling like thoſe of Hawthorn (Cratægus Oxyacantha.) Filaments inſerted into a pentapetalous corolla, ſo as to render it internally monopetalous, by connecting the edges of the petals with their flat baſes[i].

Swartz remarks, that the fruit, which he had ſeen only in an unripe ſtate, ſeems to be a drupe; that the calyx in the flower ſeems to be inferior, but becomes ſuperior, crowning the fruit.

Native of Martinico, in woods; flowering there in november.

2. The ſhoots of this ſpecies are very villoſe. The leaves are more or leſs villoſe beneath, for the moſt part entire or ſometimes but ſeldom very looſely toothletted. Nuts five-celled.—Native of Guiana.

3. This is intermediate between the firſt and ſecond. Perhaps they may be all varieties of the ſame ſpecies. —Native of the woods of Peru, where it was found by Dombey[k].

4. Native of Jamaica[l].

Swartz obſerves, that this genus is very nearly allied to *Hopea*, but is certainly different; and that it has ſtill more reſemblance to *Alſtonia*. L'Heritier unites them all, and remarks, that the imbricate calyx of Alſtonia reſembles the bractes of Symplocos, which might be conſidered as an exterior calyx. The younger Linneus called the corolla in Alſtonia one-petalled, becauſe it appears to be really ſuch in Symplocos. The border is from eight to ten-parted in Alſtonia: the Symplocos of Swartz is eight-petalled. The filaments of Alſtonia inſerted into the tube, imbricate, the outer longer, reſemble the ſtamens of Symplocos, diſpoſed in ſeveral imbricate rows, the interior of which are ſhorter. The younger Linneus adds, that the germ is ſuperior in Alſtonia, becauſe it ſeems to be ſo in Symplocos: and both Jacquin and the elder Linneus conſidered it as ſuch. Aublet has nothing about the poſition of the germ in *Ciponima*[m]. Linneus, following Jacquin, placed the genus Symplocos in the claſs Polyandria.

DESCRIPTIONS, &c.

1. This ſhrub grows to the height of eighteen or twenty feet in good ground, and divides into many branches

Digitized by Google

branches; thoſe of the white ſort grow more erect than the blue; and the purple or Scotch Lilac has its branches yet more diffuſed. The branches of the white are covered with a ſmooth bark of a gray colour; in the other two it is darker. The leaves of the white are of a brighter green: they are heart-ſhaped in all, almoſt five inches long, and three inches and a half broad near the baſe; placed oppoſite, on foot-ſtalks an inch and half in length. The buds of the future ſhoots, which are very turgid before the leaves fall, are of a very bright green in the white ſort, but thoſe of the other two are dark green. The flowers are always produced at the ends of the ſhoots of the former year, and below the flowers other ſhoots come out to ſucceed them; for that part upon which the flowers ſtand decays down to the ſhoots below every winter. There are generally two bunches or panicles of flowers joined at the end of each ſhoot; thoſe of the blue are the ſmalleſt, the flowers alſo are ſmaller, and placed thinner than either of the others: the bunches on the white are larger, but thoſe of the Scotch are larger ſtill, and the flowers fairer; this therefore makes the beſt appearance. The panicles of flowers grow erect, and being intermixed with the bright green leaves, have a fine effect; and if we add to this, the fragrancy of the flowers, it may be ranged among the moſt beautiful ſhrubs which decorate the Engliſh gardens. The flowers appear early in may, or towards the end of april, and when the ſeaſon is cool, will continue three weeks; but in hot ſeaſons they ſoon fade. The ſeeds are ripe in ſeptember. [They are of an ovate-oblong form, compreſſed, membranous at the edge, yellow or browniſh, two in each cell, of an ovate-lanceolate, coriaceous, compreſſed, deep-cheſtnut-coloured capſule; the two valves are boat-ſhaped, and the partition is thick, ſplitting into two parts, the ſeeds are faſtened to the upper part of it on each ſide [o].]

The Lilac is very common in the Engliſh gardens, where it has been long cultivated as a flowering ſhrub. It is ſuppoſed to grow naturally in ſome parts of Perſia, but is ſo hardy as to reſiſt the greateſt cold of this country. There are three varieties of this ſhrub, which not only differ in the colour of their flowers, but alſo in that of their ſhoots and leaves; one of theſe has white flowers, one blue, and the third has purple flowers; the latter is commonly known by the title of Scotch Lilac. This is the moſt beautiful of the three, and is probably called the Scotch Lilac, becauſe it was firſt mentioned in the catalogue of the Edinburgh Garden. Whether this was raiſed from ſeeds, or which other way it was obtained I could never learn; but I take it to be a diſtinct ſpecies from the others, becauſe I have raiſed many of the plants from ſeeds, which have always retained their difference, as have alſo the white, when they were propagated by ſeeds; ſo that they may be rather eſteemed as diſtinct ſorts, although by the rules now admitted for determining ſpecific differences, they may not have ſufficient marks whereby to diſtinguiſh them; and as they have been by many of the modern botaniſts joined together, I ſhall not ſeparate them.

[Gerarde and Parkinſon cultivated the blue and white Lilac, under the name of Pipe Tree or Pipe Privets. The former ſays, "I have them growing in my garden "in very great plentie." 1597.—Matthiolus's figure is engraved from a drawing, which was taken from a plant brought over from Conſtantinople by Augerius de Buſbeke, who during ſeven years was Ambaſſador to the Sultan Soliman from the Emperor Ferdinand I°. —The Lilac, now ſo common in every plantation of ſhrubs, was then a great rarity.

2. Leaves ovate-lanceolate, not cordate, yet very like thoſe of the preceding, but ſmaller. Flowers as in S. perſica. May it not be a mule plant?—Suppoſed to be a native of China [p].]

3. The Perſian Lilac is a ſhrub of much lower growth than the common ſort, ſeldom riſing more than five or ſix feet high. The ſtems are covered with a ſmooth brown bark: the branches are ſlender, pliable, extend wide on every ſide, and frequently bend down where they are not ſupported. Leaves two inches and a half long, and three fourths of an inch broad, of a deep green colour. Flowers in large panicles at the end of the former year's ſhoots, as in the former; of a pale blue colour, and having a very agreeable odour. They appear at the end of may, ſoon after thoſe of the common ſort, and continue longer in beauty, but do not perfect their ſeeds in England.

β. There is a variety of this with almoſt white flowers, but whether it came from ſeeds, or was accidentally produced from ſuckers of the purple ſort, I cannot ſay.

γ. This (which Mr. Miller makes a diſtinct ſpecies) differs in having two ſorts of leaves; thoſe on the lower part of the branches are for the moſt part entire, but broader and ſhorter than in the common Perſian Lilac, and not ending in ſuch ſharp points. The leaves on the younger branches are cut into three or five ſegments like winged leaves (pinnatifid) almoſt to the midrib. The branches are ſlenderer and weaker; their bark is of a darker brown, and the flowers of a brighter purple colour.

This was brought into Europe, before that which is now the common Perſian Lilac, under the Perſian name of *Agem*.

This ſhrub was formerly known among the nurſerymen by the name of *Perſian Jaſmin*.

[It appears from the catalogue of the Oxford garden, that it was cultivated here in 1658.—Parkinſon (1640) ſays it is now to be ſeen with Maſter Tradeſcant, at South Lambeth. He ſpeaks of the variety with cut or pinnatifid leaves.

4. Stem flexuoſe, aſcending and then hanging down, little branched, four-cornered with the corners acute, muricated with ſmall ſcattered tubercles. Branches oppoſite, remote, divaricated, reſembling the ſtem. Leaves many from a bud; the firſt ſimple, petioled, ovate, acute, ſerrate, ſmooth, thin, coming out in flowering time; the next ternate. Petioles the length of the leaves. Flowers from oppoſite buds ſolitary, two or three, yellow, on a wrinkled peduncle. Calyx three times ſhorter than the corolla, four-parted almoſt to the baſe: ſegments lanceolate. Corolla bell-ſhaped, four-parted to the middle: ſegments ovate, obtuſe. Anthers oblong, grooved, length of the calyx. Germ ſuperior, ovate, ſmooth: ſtyle length of the calyx: ſtigma headed, two-lobed. It differs from the other ſpecies, in having the calyx more deeply divided, and the corolla bell-ſhaped, not funnel-ſhaped.

Native of Japan, in Miaco, &c. often cultivated for the elegance of the flowers. It begins to flower in april [q].

Willdenow remarks, that it is totally different from the other ſpecies, and might well be conſidered as a diſtinct genus.]

PROPAGATION AND CULTURE.

1. The common Lilac may be increaſed by ſeeds or ſuckers. If the ſeeds be ſown ſoon after they are ripe, the plants will come up the following ſpring; but as the roots ſend out great plenty of ſuckers annually, few perſons take the trouble of raiſing this ſhrub from ſeeds. The plants generally flower the third year from ſeed, and when ſo raiſed, are not ſo apt to ſend out ſuckers.

The common Lilac thrives beſt upon a rich light ſoil, ſuch as the gardens near London are for the moſt part compoſed of; and there they grow to a much larger ſize, when they are permitted to ſtand unremoved, than in any other part of England. In ſtrong loam or chalk they make no progreſs. If the ſuckers be ſmall when they are taken from the old plants, they ſhould be planted in a nurſery, in rows three feet aſunder, and one foot diſtance in the rows, where they may ſtand a year or two to get ſtrength, and then they ſhould be removed to the places where they are

[o] Gærtner. [p] Matth. comm. in Dioſc. Ven. 1565. Willdenow. [q] Thunberg.

Digitized by Google

to remain. The beſt time to tranſplant theſe ſhrubs is in autumn. There is a variety or two with blotched leaves; but theſe variegations being the effect of weakneſs, whenever the ſhrubs become healthy, their verdure returns again.

3. The Perſian Lilac is uſually propagated by ſuckers, which the roots ſend out in great plenty; theſe ſhould be carefully taken off from the old plant in the autumn, and planted in a nurſery, in the ſame manner as directed for the firſt, where they may grow two years to get ſtrength, and then be tranſplanted to the places where they are deſigned to remain. A better way of raiſing them, is by laying down the young branches, which in one year will be ſufficiently rooted to tranſplant, and may then be treated in the ſame way as the ſuckers.

TABERNÆMONTANA. (*So named by Plumier, in memory of James Theodore ſurnamed Tabernæmontanus from Berg-Zabern, the place where he was born. He publiſhed* Kraeuterbuch, 1589, *and figures of plants*, 1590, *in an oblong quarto form. He was phyſician to the Elector Palatine, and died in* 1590.)

Lin. gen. n. 301. *Reich. n.* 327. *Schreb. n.* 424. *Plum.* 30. *Juſſ.* 145.

Claſſ. 5. 1. Pentandria Monogynia.

Nat. order of *Contortæ*. *Apocineæ* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* five-cleft, acute, converging, very ſmall.

COR. one-petalled, funnel-form: *tube* cylindric, long: *border* five-parted, flat; *ſegments* obtuſe, oblique.

Nectary glands five, bifid, ſtanding round the germ.

STAM. *Filaments* five, very ſmall, from the middle of the tube. *Anthers* converging.

PIST. *Germs* two, ſimple. *Style* awl-ſhaped. *Stigma* oblong, headed.

PER. *Follicles* two, horizontally reflexed, ventricoſe, acuminate, one-celled, one-valved.

SEEDS numerous, ovate-oblong, obtuſe, wrinkled, immerſed in pulp, imbricate.

ESSENTIAL CHARACTER.

Contorted. *Follicles* two, horizontal. *Seeds* immerſed in pulp.

SPECIES.

1. Tabernæmontana citrifolia. *Citron-leaved Tabernæmontana.*

Lin. ſpec. 308. *ſyſt.* 255. *Reich.* 1. 600. *Willd.* 1. 1244. *hort. cliff.* 76. *Jacqu. amer.* 38. *t.* 175. *f.* 13. *pict.* 25. *t.* 40.

T. citri foliis undulatis. *Plum. gen.* 18. *ic.* 248. *f.* 2.

Leaves oppoſite ovate, flowers lateral glomerate-umbelled.

2. Tabernæmontana laurifolia. *Laurel-leaved Tabernæmontana.*

Lin. ſpec. 308. *ſyſt.* 255. *Reich.* 1. 600. *Willd.* 1. 1244. *Jacqu. amer.* 39. *pict.* 25. *Brown. jam.* 182. *Amm. herb.* 212.

Nerium arboreum, folio latiore obtuſo, flore luteo minore. *Sloan. jam.* 2. 62. *t.* 186. *f.* 2.

Leaves oppoſite oval bluntiſh.

Leaves lanceolate oppoſite, peduncles in pairs one-flowered pendulous.

19. Tabernæmontana bovina.
Lour. cochinch. 118. *ed. Willd.* 145.

Leaves lanceolate oppoſite, peduncles ſolitary many-flowered.]

DESCRIPTIONS, *&c.*

1. This riſes with an upright woody ſtalk to the height of fifteen or ſixteen feet, covered with a ſmooth gray bark, abounding with a milky juice, and ſending out ſeveral branches from the ſide, which grow erect, and have many joints. Leaves thick, milky, from five to ſix inches long, and two inches broad in the middle, drawing to a point at each end; they are of a lucid green, have many tranſverſe veins, and ſtand oppoſite on footſtalks an inch long. The flowers come out in roundiſh axillary bunches; they are ſmall, of a bright yellow colour, and have an agreeable odour. The tube of the corolla is half an inch long, and the brim is cut into five acute points, which ſpread open like thoſe of common Jaſmin.

[According to Jacquin, it is a ſmall tree eight feet high. Leaves very ſhining, waved by the contraction of the veins, green but ſo as that the milk in which they abound appears through. Flowers few, white. Stamens within the tube of the corolla. Follicles always green. Seeds brown, lodged in a ſoft orange pulp. The French call it *Bois laiteux.*

Native of Jamaica, Martinico, &c. and the iſland of Namoka in the South Seas.—Cultivated in 1739, by Mr. Miller[r].]

2. This riſes with a ſhrubby ſtalk twelve or fourteen feet high, ſending out a few branches towards the top which grow erect. Leaves four inches long and two broad, of a lucid green colour. The flowers are produced in a ſort of umbel from the ſide of the branches; they are ſmall, yellow, and have an agreeable odour.

[Jacquin remarks, that it is an upright little tree, five feet high, branched, milky, having the habit of the preceding. Flowers yellow, ſmelling very ſweet, few. Stamens concealed within the corolla. Fruits green.

Native of Jamaica, St. Domingo, and other iſlands of the Weſt Indies.—Cultivated in 1768 by Mr. Miller[s].

3. A ſhrub, ſending out from its root ſeveral ſtems of the length of five or ſix feet: they are woody and branched; with the branches oppoſite, as well as the leaves, which are ovate-oblong, acuminate, undulated at the margin, ſmooth and green above, and ſubtomentoſe and whitiſh beneath: flowers corymboſe and terminal, ſituated between the forkings of the branches; they are of a yellow colour and of an agreeable ſmell. —Native of Guiana[t].

4. Branches round, ſmooth, dichotomous, even. Leaves oppoſite at each diviſion, and another pair between them; one three or four inches long, ſhortly petioled, elliptic-lanceolate, the other oppoſite under the diviſion ſeveral times ſhorter, ſeſſile, ſubcordate, or as between the diviſion, only a little ſhorter, the ſame ſtructure with the other, ſeſſile, one ſide of the baſe ſhorter than the other: all acuminate, with the point half an inch long and ſharp; the margin is a little reflexed, waved and obſcurely crenate; the ſurface veinleſs, remotely nerved, paler beneath. Peduncles at the diviſions and tops of the branches, five to ſeven-flowered, ſolitary, filiform, an inch long, ſmooth. Pedicels alternate, approximating, a little ſhorter than the common peduncle, one-flowered. Bractes minute, in pairs, at the baſe of the pedicels. Calyx ſmooth, with linear-lanceolate ſegments. Corolla half an inch in diameter, with a linear narrow tube, a little wider at the baſe; ſegments of the border lanceolate, three times ſhorter than the tube; the throat has a few ſilky villoſe hairs. This ſpecies was ſent by von Rohr under the name of *T. echinata*; probably he was led to ſuppoſe that it was the ſame with the *echinata* of Aublet, by the roughneſs of the follicles; but it does not correſpond either with the deſcription or figure of Aublet.—Native of Cayenne[u].

5. This is an upright little tree or ſhrub, eight feet high, milky, branched; the branchlets dichotomous. Leaves oval, attenuated to each end, acute, quite entire, ſhining, petioled, very unequal in ſize. Common peduncles irregular, two-flowered or three-flowered, ſolitary by the ſides of the laſt forking of the branchlets: the pedicels ſupported by a ſtipule. Flowers void of ſcent, very large when compared with thoſe of the other ſpecies. Calyx-leaves flat, whitiſh, very looſe, unequal in length, the two outer cordate and very wide, the three others oblong and narrow. Tube of the corolla above the calyx twiſted, and twice as long as the calyx; the border very wide. Glands roundiſh, obtuſe, ſmall, grooved externally, united into one at the ſides. Stamens in the middle of the tube. Stigma large with a cloven top. Follicles roundiſh-ovate, acuminate, ſmooth, green. The flower has ſomething in common with Echites and Cerbera, but the fruit is that of a Tabernæmontana.

According to Linneus, the leaves are lanceolate-ovate; the peduncles ſubtriflorous; the calyx-leaves ſcarioſe and white; the two outer cordate, the reſt narrow.

Native of Carthagena in Spaniſh America; flowering there from july to ſeptember.

6. This is an elegant upright little tree or ſhrub, with the trunk ſix feet high, but ſometimes double that height. Leaves acute, quite entire, ſcarcely waved, half a foot long. Cymes ample, handſome, convex, denſe, axillary. Flowers without ſcent, dirty white or reddiſh brown, about forty in a cyme, the ſize of thoſe in *laurifolia* and *citrifolia*. Calyx-leaves flat, lanceolate-oblong. Tube of the corolla, quinquangular-ventricoſe at the baſe. Stamens in the enlarged baſe of the tube. Stigma margined at the baſe. Follicles oblong, very blunt, curved in, very large, reddiſh with ruſt-coloured ſpots. One of each pair is commonly abortive. The pulp is orange-coloured.

Frequent in the woods and coppices about Carthagena in New Spain; flowering in july and auguſt.

7. This is an upright little tree or ſhrub, ſix feet high, branched and milky. Leaves oval-lanceolate, acute, flat, ſhining very much, oppoſite. Peduncles few-flowered. Flowers white, ſmelling very ſweet. Tube of the corolla ſlightly widening at the top and bottom. Filaments in the upper part of the tube, with the anthers ſtretched beyond it. Follicles ſubovate or oblong, always acuminate, green, ſhining, approaching to thoſe of *citrifolia*, but commonly twice or three times ſmaller. Pulp orange-coloured. When it begins to flower, it is generally without leaves. Frequent about Carthagena in woods and coppices[x].

8. This is a ſhrub, a fathom in height, with a ſmooth, aſh-coloured bark. Branches ſubdichotomous, ſpreading, round, with four-cornered ſmooth branchlets. Leaves entire, very ſlightly nerved, ſmooth on both ſides, deep green above, pale beneath. Petioles middling, angular, ſmooth. Peduncles terminating, filiform, half an inch long: pedicels longer than the peduncles, one-flowered. Flowers whitiſh or yellowiſh, ſmall. Calycine ſegments erect, acute. Tube of the corolla half an inch long, ſwelling at the baſe and in the middle: ſegments at the border roundiſh, waved, twiſted. Filaments inſerted into the middle of the tube. Anthers ovate, within the tube. Stigma headed.—Native of Jamaica[y].

9. Branches ſmooth, roundiſh, under the leaves obſcurely four-cornered, at top pale green. Leaves oppoſite, five inches long, one a little ſmaller than the other, produced into a point an inch in length, acute at the baſe, ſmooth on both ſides, above bright

[r] Hort. kew. [s] Idem. [t] Aublet. [u] Vahl. [x] Jacquin. [y] Swartz.

Digitized by Google

green, obſcurely nerved, with a longitudinal groove in the middle of the leaf; beneath pale, veinleſs but tranſverſely nerved: nerves numerous, diſtant, yellowiſh, as is alſo the midrib. Petiole very ſhort. Stipule a ſhort rim, ſurrounding the branch, and at length evaneſcent. Peduncles at firſt terminating, then axillary, ſolitary, very ſhort, bifid: each branchlet three or four-flowered. Flowers on very ſhort pedicels, an inch and half long, ſmooth. Calycine ſegments rounded, equal, thick. Tube of the corolla an inch long, round, thickened above the middle, then narrowed, ſomewhat fleſhy, ſegments of the border linear, obtuſe, erect, curved in, twiſted a little, doubled together from the ſides being bent back. Throat ſmooth. Nectary a fleſhy undivided gland ſurrounding the germs. Filaments ſcarcely any. Anthers ſubſeſſile a little above the middle of the tube, linear, very narrow, acute, ſhorter than the throat. Germs ovate, ſmall. Style length of the ſtamens. Stigma headed, mucronate, ſurrounded at the baſe by a minute membrane. Follicles an inch and half long, reflexed, curved in a little on each ſide, oblong-three-ſided, with the back convex, having a groove along the middle, and margined with a raiſed line on each ſide; the ſides flat, the belly rounded and ſtraight; blunt at the baſe, and ſharpiſh at the tip. Seeds in four rows, horizontal, ſtriated, brown, with one extremity of the future obverſe gradually narrowed, acute, the other declining towards the tip, wider, obliquely tranſverſe at the tip itſelf, the margin acute. Navel ventral, towards the ſharper tip, turning towards the pedicel. Aril incomplete, fleſhy, irregular, compreſſed, thicker towards the navel.—It differs from *T. diſcolor*, in having many-flowered peduncles, very ſhort pedicels, the calycine ſegments obtuſe, the flowers large, and the anthers linear; from *grandiflora* by the calycine ſegments being equal: from *cymoſa* in having the cymes few-flowered, the calycine ſegments rounded, and the tube of the corolla equal at the baſe: from *echinata* of Aublet, by the follicles not being echinate.—Native of the iſland of Trinidad: where it was found by Ryan [a].

10. This grows in the iſland of St. Mauritius; and flowers in the Auſtrian ſtoves in the month of july and auguſt. It is a ſhrub of ten feet high, branchy, with an upright ſtem of an arm's thickneſs: the whole ſhrub is ſmooth, and abounds with a milky juice: the leaves are oppoſite, on ſhort footſtalks, and are of a narrow linear-lanceolate ſhape, entire, gloſſy, and of a bright green colour: the flowers are of a pale yellowiſh colour [a].

11. Branches dichotomous, thickly warted at top from the fallen leaves, ſmooth, round. Leaves on ſhort petioles, from two to three inches in length, nearly equal, ſharp at both ends, very ſmooth and even, veinleſs, tranſverſely remotely very finely and indiſtinctly nerved, quite entire, ſcarcely waved, paler beneath. Peduncles axillary, ſolitary, twice as long as the petiole, three or four-flowered: pedicels alternate, very ſhort: at the baſe of each a minute linear bracte, which is deciduous. Calyx ſmooth, with oblong acute ſegments. Corolla half an inch in diameter: ſegments longer than the tube, ſomewhat wedge-ſhaped, ſmooth, ſcarcely pubeſcent at the baſe within. Anthers prominent beyond the tube of the corolla, beaked. The *perſicariæfolia* of Jacquin is allied to this, but differs in having the leaves a little veined beneath; the peduncles bifid with the branches three or five-flowered; and the tube of the corolla twice as thick.—Native of Porto Ricco, where it was found by von Rohr [b].

12. Stem herbaceous, round, gradually attenuated, ſimple, ſmooth, a foot high or a little more. Leaves ſcattered, two, three or four together, elliptic or lanceolate-acuminate, entire, nerved, ſmooth, beneath a little pale, even, ſpreading, an inch and half long, the upper ones ſmaller. Petioles very ſhort, gradually widening into the leaf, in a ſort of whorl, four, three or two together, approximating, not oppoſite. Flowers terminating in racemes. Peduncles capillary, alternate, one-flowered, a line in length. Under each peduncle a briſtle-ſhaped bracte, ſhorter than the peduncle. Calyx five-parted, many times ſhorter than the corolla, with briſtle-ſhaped ſegments. Corolla blue, ſmall. Very nearly allied to *T. Amſonia*, but has narrower leaves, attenuated to both ends, ſcarcely netted beneath, not oppoſite but two, three or four near together in a ſort of whorl; the ſtem alſo is round, not angular.—Native of Japan [c].

13. This is a ſmall tree or ſhrub from one to two fathoms in height, with a trunk a foot thick, covered with a brown milky bark, aſh-coloured on the branches. Leaves on ſhort thick petioles, rounded-oblong, contracted next the petiole, and ending in a long point, of a ſolid texture, milky, of a dark ſhining green above, beneath paler: the midrib is white, and many parallel nerves iſſue from it obliquely. The flowers come out at the end of the twigs on round ſlender weak peduncles; the corolla is white; the calyx-leaves are pale green and pointed. Follicles rounded-oblong, pointed at the end, when ripe of a golden yellow without, and paler yellow within. Seeds five, ſix or ſeven oblong, irregular.

Native of Malabar, where it flowers great part of the year, particularly in the rainy ſeaſon [d].]

14. This is a perennial plant, ſending up in the ſpring two or three herbaceous ſtalks near a foot high. The flowers are produced in ſmall terminating bunches, white and void of ſcent. It had the name of Amſonia given it by Mr. Clayton, who firſt diſcovered it in Virginia. [It is allied both to *Cameraria* and this genus. Leaves wide lanceolate, ſubſeſſile, even. Branches alternate. Raceme compound, terminating. Follicles reflexed, round, long, acuminate. Seeds cylindrical, rugged. Anthers within the throat of the corolla. Stigma headed above a membranaceous ring [e].

Native of North America. Cultivated in 1759, by Mr. Miller. It flowers in may and june.

15. It is a perennial plant, native of North America; and was introduced in 1774 by Mr. James Gordon. It flowers in may and june [f].

16. Branches dichotomous, round, ſmooth, purpliſh brown: branchlets compreſſed, with the two oppoſite ſides grooved. Leaves on ſhort petioles, oppoſite, four or five inches long, one ſmaller than the other; they are ſharp at both ends, indiſtinctly veined, ſomewhat ſhining on the upper ſurface, the uppermoſt often ruſſet-coloured beneath, very ſmooth on both ſides, flat at the edge, quite entire. Inſtead of a ſtipule there is a rim on both ſides between the petioles. Peduncles from every other axil, very ſhort, ſolitary. Pedicels four, ſometimes three, an inch long, filiform, purpliſh, ſmooth, without bractes, one-flowered. Segments of the calyx awl-ſhaped. Segments of the corolla linear-lanceolate, longer than the tube, hoary within, at the baſe: tube gradually narrowing upwards.—Native of Surinam [g].]

17. This riſes with a woody ſtalk ten or twelve feet high, covered with a wrinkled gray bark, and ſending out many branches towards the top. Leaves of a lucid green, and a thick conſiſtence, five inches long and two inches and a half broad, rounded at both ends, but terminating with an acute point, and placed on ſhort footſtalks. The flowers come out in pretty large roundiſh bunches at the ends of the branches; they are ſmaller than thoſe of *citrifolia*, white, and have an agreeable odour. The follicles are ſhorter and rounder. It was diſcovered by William Houſtoun, M. D. in the year 1730, growing naturally at La Vera Cruz.

[18. This is a ſhrub five feet high, almoſt upright, branched. Leaves quite entire, ſhining. Peduncles lateral, long. Corolla ſalver-ſhaped, white; tube cylindrical, long, ſlender, ſwelling at the baſe. Stamens above the middle of the tube. Style ſhorter than the ſtamens, with an ovate bifid ſtigma. Follicles longiſh, ſubventricoſe, acuminate, toruloſe, ſmooth. Seeds oblong, angular, in a red pulp.—Native of Cochinchina.

[a] Vahl. ecl. [b] Jacquin. [b] Vahl. [c] Thunberg. [d] Hort. malab. [e] Linn. ſpec. [f] Hort. kew. [g] Vahl.

Digitized by Google

19. This is an upright ſhrub four feet high, with the branches reclining. Leaves quite entire, ſmooth. Peduncles axillary, almoſt upright, bearing about five flowers. Corolla white, ſalver-ſhaped. Follicles divaricating, recurved, ſhort, ſwelling, acuminate, not toruloſe. Seeds roundiſh, angular, in a red pulp.

Native of Cochinchina; where it is eſteemed emollient; the milky viſcid juice is reputed excellent for aſſiſting in the extraction of darts or thorns[h].

Loureiro has named theſe two ſpecies from the ſimilitude of the follicles to the horns of the Buffalo and Ox.]

PROPAGATION AND CULTURE.

Theſe plants, being moſtly natives of the Weſt Indies, are very impatient of cold, and will not live in this country, unleſs they are placed in a warm ſtove; they may be propagated by ſeeds, which muſt be procured from the countries where the plants grow naturally; theſe ſhould be ſown early in the ſpring on a hot-bed, and when the plants are come up, and are fit to remove, they muſt be carefully tranſplanted into ſmall pots filled with light rich earth, and then plunged into a hot-bed of tanners bark, being careful to ſhade them in the heat of the day until they have taken new root; after which time, they muſt have free air admitted to them every day when the weather is warm; but if the nights ſhould prove cold, the glaſſes of the hot-bed ſhould be covered with mats every evening, ſoon after the ſun goes off from the bed. Theſe plants muſt be often refreſhed with water, but it muſt not be given to them in large quantities, eſpecially while they are young, for as they are full of a milky juice, they are very ſubject to rot with much moiſture.

The plants may remain during the ſummer ſeaſon in the hot-bed, provided the tan is ſtirred up to renew the heat when it wants, and a little new tan added; but at Michaelmas, when the nights begin to be cold, the plants ſhould be removed, and plunged into the bark-bed in the ſtove; where, during the winter ſeaſon, they muſt be kept in a moderate degree of warmth, and in cold weather they ſhould have but little water given them, leſt it ſhould rot them. The plants ſhould conſtantly remain in the ſtove, where, in warm weather, they may have free air admitted to them by opening the glaſſes, but in cold weather they muſt be kept warm. With this management the plants will thrive and produce their flowers, and as their leaves are always green, they will make a pleaſant diverſity amongſt the tender exotic plants in the ſtove.

Theſe plants may alſo be propagated by cuttings during the ſummer ſeaſon, which ſhould be cut off from the old plants, and laid to dry in the ſtove five or ſix days before they are planted, that the wounded parts may heal, otherwiſe they will rot. Theſe cuttings ſhould be planted in pots filled with freſh light earth, and plunged into the hot-bed of tanner's bark, and cloſely covered with a hand-glaſs, obſerving to ſhade them from the ſun in the middle of the day in hot weather, as alſo to refreſh them now and then with a little water. When the cuttings have taken root, they may be tranſplanted into ſeparate pots, and treated in the ſame manner as thoſe which are raiſed from ſeeds.

14. This ſpecies and the next will live in the open air here, provided they are planted in a warm ſituation. They love a light ſoil, rather moiſt than otherwiſe; but if they be planted in dry ground, they ſhould be frequently watered in dry weather. Not producing ſeeds in England, they are increaſed by offſets, and as they do not ſend out many of theſe, they are at preſent rare in our gardens.

Leontice Leontopetaloides. *Lin. ſpec.* 448.

Leontopetaloides. *Amm. in act. petrop.* 8. 211. *t.* 113.

DESCRIPTION, *&c.*

Root tuberous, compoſed of many tubers heaped together, here and there emitting fibres. Radical leaf ſubſolitary, petioled, ternate or biternate; leaflets laciniate-pinnatifid, acute, even, ſpreading, decurrent a little along the ſides of the petioles, a long ſpan or a foot in length. Petiole round, fiſtular, grooved (in the cultivated variety ſmooth, variegated with dirty ſpots) at the very bottom ſheathing a ſcape, ſpreading, even. Scape half a fathom in height, herbaceous, fiſtular, grooved towards the top, erect. Umbel terminating, ſeſſile, quite ſimple. Involucre about ſeven-leaved; leaflets two inches long, the two outer ſeſſile, pinnatifid, the reſt ſpatulate even, the lamina roundiſh, with a very ſhort point at the end. Peduncles four to eight, almoſt the length of the involucre, quite ſimple, ſomewhat angular, one-flowered, ſpreading. Eight or twelve very long threads, many times longer than the involucre, ſpreading, hanging out beyond the umbel, twiſted in, interpoſed between the peduncles, are inſtead of bractes. Anthers twelve, on very ſhort filaments, or ſubſeſſile. Germs three, or one three-lobed. Styles three, very ſhort. Stigmas obcordate, two lobed. Berry black, ovate, wrinkled, obſcurely angular, crowned with the calyx, three-celled, many-ſeeded: when unripe hexangular, fleſhy, two inches in diameter. Seeds brown[i].

According to Gærtner, the calyx is ſix-cleft; the number of anthers uncertain, (ſix only ſeem to have been reckoned by Solander, who alſo regarded the petals as cowled filaments) ſtyle one, with an orbicular, ſix-rayed ſtigma. Berry membranaceous, crowned with the whole permanent flower, ribbed with ſix raiſed nerves, having a watery pulp in it. Seeds ſubovate, variouſly angular from their mutual preſſure, longitudinally ſtriated, of a pale ruſſet colour.

Native of the Eaſt Indies, China, Cochinchina, Banda and the Society iſles.

The root is red, the ſize of a man's fiſt, roundiſh[k]. In its natural ſtate it is one of the moſt bitter and acrid, but loſes ſomething of theſe qualities by culture. The raw root is raſped, and waſhed frequently in water, when a white meal falls to the bottom like ſtarch; this is again waſhed twice or thrice, till no more acrimony can be perceived in the water.

[h] Loureiro.

[i] Forſt. eſcul. [k] Loureiro.

Digitized by Google

The meal is then dried in the ſun. The firſt infuſions are thrown away carefully, being looked upon as noxious and even deadly. In Otaheite and the other Society iſles, they make of this meal a taſteful nouriſhing, gelatinous cake like Salep. In Banda, where Sago bread is not common, they uſe this as a ſuccedaneum, and it is even preferable to the other. They alſo apply it as a plaſter to deep wounds[t]. The petioles and ſtalk boiled a long time, loſe their acrimony, and are rendered fit for food, as well as the roots in China and Cochinchina[u].

DESCRIPTIONS, &c.

1. [Stem a foot and half high, almoſt upright, ſmooth, diffuſed. Leaves deeply pinnatifid, (pinnate with a winged rachis) the ſegments lanceolate, ſerrate ſmooth, dark-green; paler at the back, and punched. Flowers ſolitary, terminating, gold-coloured, on a long upright peduncle. Calyx eight-grooved, eight-toothed, ſmooth and even. Corollets in the ray about thirty, grooved and plaited. Seeds blackiſh[v]. A flower that I have before me is eight-grooved and eight-toothed, as Loureiro deſcribes it; but it has only five large ligular florets, or ſemiflorets, as Tournefort and Dillenius call them; but between theſe there are many fiſtular florets, which are imperfect as well as the radical ones, but have ſeeds. The colour is a deep reddiſh orange, bordered with yellow, and entirely yellow on the outſide.] But there are ſeveral varieties of the French Marygold, differing in ſize, and greatly in colour, ſome beautifully variegated, and others quite plain. [Dillenius figures and deſcribes one with oblong red ſpots dividing the orange. Curtis figures another, which is gold-coloured with red ſtripes. He remarks that the common ſmall ſort has a ſtrong diſagreeable ſmell, and is of more humble growth, with more ſpreading branches, and ſmaller flowers, that have uſually a greater portion of yellow: the larger one, commonly called the ſweet-ſcented, with the flowers bigger, and having a variety of rich tints; the ſmell of this is ſo modified as to be leſs diſagreeable than the other, but it can ſcarcely be called ſweet. From the ſeed of both varieties, ſome riſe extremely double, and others ſingle.

Dodonæus remarks the punches or perforation of the leaves; and adduces ſome inſtances, proving the plant to be of a poiſonous nature; but it ſeems only to be warm and aromatic. He affirms that it grows ſpontaneouſly in Africa, and was firſt brought into

[t] Forſt. eſcul. [u] Loureiro. [v] Loureiro.

Europe

Digitized by Google

Europe by the Emperor Charles V. after his expedition againſt Tunis. But that was in the year 1535; and Fuchſius in 1542, figures the plant under the name of Tagetes indica; it has never been found in Africa. Hernandez mentions it in his hiſtory of Mexico: and the variety figured by Dillenius, which flowered in the Eltham garden in 1727, was produced from Mexican ſeeds [o]. Thunberg mentions it as cultivated in Japan; and Loureiro, in China, Cochinchina, and many parts of India; but not as indigenous of thoſe countries.—It was common with us in Gerarde's time, 1597, and appears in the catalogue of his garden, 1596 [p].]

It flowers from the beginning of july, till the froſt puts a ſtop to it.

2. [Stem three or four feet high, ſtraight, round, green, dividing from the middle into many branches, each bearing one large flower. Leaves long, pinnate, leaflets dark-green. Flowers yellow, from brimſtone to orange colour.—Receptacle flat or ſomewhat convex, hollow-dotted, naked, ſmooth. Seeds linear-oblong, narrower downwards, compreſſed a little, angular, ſtriated, ſmooth, black with the point of the baſe whitiſh. Down longer than half the ſeed, pale ſtraw-coloured, five-leaved: rays chaffy-rigid, unequal, linear, ſmooth, ſhining, acuminate or obtuſe [q].]

Of this there are the following varieties:

1. Pale yellow or brimſtone-colour.
2. Deep yellow.
3. Orange-coloured: all theſe with ſingle, double and fiſtulous flowers.
4. Middling African, with orange-coloured flowers.
5. Sweet-ſcented African.

[Parkinſon remarks, that the flower "is of the "very ſmell of new wax, or of an honie combe, and "not of that poiſonfull ſent of the ſmaller kindes."

It is a native of Mexico, and was cultivated by Gerarde in 1596 [r].]

3. This is a plant of taller growth than either of the former. Stem about ten feet high, branching a little towards the top: the branches grow erect. Leaves narrower than either of the other. The peduncles ſtand erect, cloſe to the ſtem; and ſuſtain three or four ſmall white flowers, which appear very late in autumn. This plant has very little beauty, and is preſerved only for the ſake of variety.

[Dillenius ſays that it grew to the height of ten or eleven feet in a pot, and ſtill higher in the open ground, with ſtems as thick as the human arm, ſtraight, rigid, round, ſmooth, red, leafy from top to bottom. The leaves are ſmaller, ſmooth, and have the ſame ſtrong ſmell. the ends of the ſtems and branches run out into a ſpike which is a foot or more in length, and is compoſed of axillary umbels of flowers, having little bractes here and there on the pedicels. Calyxes entire, oblong, tubular, ſmooth, divided into three or four ſmall ſegments, not ſtriated but ſmooth and even, from round three-ſided, variegated and as it were dotted with ſhort brown lines. Corollas very ſmall, yelloviſh white, having two, three or four florets in the ray, which are ſucceeded by oblong, ſlender, compreſſed blackiſh ſeeds, terminated by four or five dry whitiſh leafy threads, three ſhorter and two longer. Receptacle naked. This ſpecies is eaſily diſtinguiſhed by its tallneſs, the ſmallneſs of the flowers, and their peculiar manner of growth.

It flowered in the Eltham garden, towards the end of autumn in 1728; and was raiſed from ſeeds taken from dried ſpecimens brought over by Mylam a ſurgeon from Buones Ayres. It ſeems to be the ſame with the Tagetes Chilienſis exiguo flore, and flore minimo, of Feuillee, *obſ. phyſ.* 3. *Hiſt. plant. med.* 64 [s].]

4. This riſes with an upright ſtalk about two feet high, ſending out a few branches towards the top. Leaves heart-ſhaped upon long ſlender footſtalks; the lower ones two inches and a half long, and an inch and half broad towards the baſe, ending in very acute

[o] Hort. elth. [p] Hort. kew. [q] Gærtner. [r] Hort. kew. [s] Dillen. in hort. elth.

points, in ſhape like thoſe of the black Poplar, rough to the touch, and ſlightly crenate on the edges. The ſtalks and branches are each terminated by one large yellow flower, ſtanding upon a long naked peduncle. Calyx ſhort. Florets of the ray much longer than the calyx; thoſe of the diſk are of a deep yellow colour, and make a good appearance. This plant was diſcovered by Dr. Houſtoun, growing naturally at La Vera Cruz in New Spain.

PROPAGATION AND CULTURE.

1. 2. Theſe plants being annual, muſt be propagated from ſeeds every ſpring; they may be ſown upon a moderate hot-bed the beginning of April; and when the plants are come up, they ſhould have plenty of freſh air, for if they are drawn too much, they will not afterward become handſome, notwithſtanding they have all poſſible care taken of them. When they are about three inches high, they ſhould be tranſplanted on a very moderate hot-bed, which may be arched over with hoops, and covered with mats, for theſe plants are hardy enough to be brought up without glaſſes; in this bed they ſhould be planted about ſix inches aſunder each way, obſerving to water and ſhade them until they have taken root; but as the plants acquire ſtrength, they ſhould be inured to bear the open air by degrees, and about the beginning of may they ſhould be taken up, with a ball of earth to the root of each plant, and planted into the borders of the parterre-garden, or into pots, for furniſhing the courts, &c. ſhading them carefully from the ſun till they have taken new root, and alſo ſupplying them duly with water. When their flowers appear, if any ſhould prove ſingle, the plants ſhould be deſtroyed, and then thoſe in pots may be removed to the court where the ſeveral varieties, being intermixed with other annual plants, afford an agreeable variety.

The varieties, eſpecially of the African Marygold, are very ſubject to vary; ſo that unleſs the ſeeds are very carefully ſaved from the fineſt flowers, they are very apt to degenerate; nor ſhould their ſeeds be too long ſown in the ſame ground; but they who are deſirous of having theſe flowers in perfection ſhould exchange their ſeeds with ſome perſon of integrity, whoſe ſoil is of a different nature, at leaſt every other year. If this be done, the varieties may be continued in perfection.

3, 4. Theſe being not ſo hardy as the others, the ſeeds ſhould be ſown earlier in the ſpring upon a good hot-bed; and when the plants are fit to remove, they ſhould be tranſplanted to a freſh hot-bed, at about three inches diſtance every way, obſerving to ſhade them from the ſun till they have taken new root; then they ſhould be treated in the ſame way as the Amaranthus, and other tender annual plants, being careful not to draw them up weak; when they have ſpread ſo as to meet each other, they ſhould be taken up with balls of earth to their roots, and planted in pots with rich light earth, and plunged into a hot-bed under a deep frame, where the plants may have room to grow, being careful to ſhade them from the ſun till they have taken new root, after which they muſt have air and water in proportion to the warmth of the ſeaſon; and when the plants are grown up too tall to remain in the frame, they ſhould be removed to an airy glaſs caſe, where they may ſtand to flower and ripen their ſeeds.

DESCRIPTIONS, *&c.*

This tree grows to a very large ſize in thoſe countries where it is a native. The ſtem is very large, covered with a brown bark, and divides into many branches at the top, ſpreading wide every way. Leaves pinnate, compoſed of ſixteen or eighteen pairs of leaflets, without a ſingle one at the end: they are about half an inch long, and a ſixth part of an inch broad, of a bright green, a little hairy, and ſit cloſe to the midrib. The flowers come out from the ſide of the branches, five, ſix or more together, in looſe bunches. The pods are thick and compreſſed; thoſe from the Weſt Indies from two to five inches in length, with two, three or four ſeeds; thoſe from the Eaſt Indies are almoſt twice as long, and contain five, ſix and even ſeven ſeeds. Plants raiſed from both theſe are ſo like as not to be diſtinguiſhed; the difference in the ſize of the pods therefore is probably owing to ſoil or culture. [Gærtner ſeems to think them diſtinct, by his trivial name of *occidentalis*.

The calyx is ſtraw-coloured, and the petals are yelloviſh beautifully variegated with red veins. Peduncles about half an inch long, each furniſhed with a joint, at which the flower turns inwards. Filaments commonly three, but in ſome flowers four, in others only two; they are purple, and the anthers are browniſh[t].

According to Loureiro, the leaves are not always without a terminating leaflet: the leaflets are ovate-oblong, quite entire, ſmooth, ſeſſile, ſpreading during the day, but cloſing ſo as to lie over each other in the night. The flowers are in ſmall lateral bunches on a long upright common peduncle. Corolla yellow with red veins: the three petals ovate-lanceolate, unequal, ſpreading, longer than the calyx. Filaments longer than the corolla. Legume half a foot long, thick, curved a little, one-celled.

Gærtner conſiders the pod as divided into three or four cells, each lined with a very thin membrane.

Swartz deſcribes the calyx as four-leaved: the three petals unequal, ſpreading, deciduous, with a void left as it were for two others; the two upper ones the length of the calyx, ovate, acute, and channelled at the baſe, the middle one ſmaller and cowled: three fertile filaments, and ſeven very ſhort barren ones; anthers oblong verſatile: germ ſabre-ſhaped, bowed, three-cornered: legume one-celled, containing from three to ſix ſeeds.

Linneus retained this tree to the laſt in the claſs Triandria, though he knew from Jacquin that the filaments are united at the baſe; but it is at length placed in the claſs Monadelphia by Schreber, Scopoli, Loureiro, and Woodville. Browne remarked, that it approaches near to the Diadelphia claſs.

It ſeems to be a native both of the Eaſt and Weſt Indies, and of Egypt, if not Arabia. In the Weſt Indies it flowers in october and november. It has not often flowered in Europe. Jacquin ſaw it once in the Vienna garden; and it has lately flowered in the royal garden at Kew, in june and july. Johnſon, the editor of Gerarde's herbal, ſays that he has ſeen young plants of the Tamarind in the garden of his deceaſed friend Mr. Tuggy, but that they ſtill died at the approach of winter. It was therefore cultivated here before 1633; the year in which that edition of Gerarde's herbal was publiſhed.

The timber of the Tamarind tree is heavy, firm and hard: ſawn into boards, it is converted to many uſeful purpoſes in building[u].

The fruit is uſed both in food and medicine. In many parts of America, particularly in Curaçao, they eat abundance of it raw, without any inconvenience, except gently relaxing the body. In Martinico alſo they eat the unripe fruit, even of the moſt auſtere kind[x].]

The Tamarinds which are brought from the Eaſt Indies are darker and drier, but contain more pulp; being preſerved without ſugar they are fitter to be put into medicines than thoſe from the Weſt Indies, which are much redder, but being preſerved with ſugar, are more pleaſant to the palate.

[We have the pods ſometimes with the ſhells, from the Weſt Indies; but moſt commonly the pulp with the ſeeds, connected together by numerous tough ſtrings is brought over preſerved in ſyrup. The pods are gathered in june, july and auguſt, when full ripe. The fruit, taken out of the pod and cleared from the ſhelly fragments, is placed in layers in a caſk, and boiling ſyrup, juſt before it begins to granulate, is poured in till the caſk is filled. A more elegant method of preſerving this fruit is, with ſugar well clarified with eggs, till a clear tranſparent ſyrup is formed[y]. But as a principal medicinal purpoſe of the pulp depends upon its acidity, it would be of more utility if it were ſent over in the pods[z].

This fruit, the uſe of which was firſt learned from the Arabians, contains a larger proportion of acid with the ſaccharine matter, than is uſually found in the acid-dulcet fruits, and is therefore not only employed as a laxative, but alſo for abating thirſt and heat in various inflammatory complaints, and for correcting putrid diſorders, eſpecially thoſe of a bilious kind; in which the cathartic, antiſeptic and refrigerent qualities of the fruit have been found equally uſe-

[t] Woodville. [u] Long. [x] Jacquin. [y] Long. [z] Cullen.

Digitized by Google

ful. When intended merely as a laxative, it may be of advantage to join it with manna, or purgatives of a ſweet kind, by which its uſe is rendered ſafer and more effectual. Three drams of the pulp are uſually ſufficient to open the body; but to prove moderately cathartic, one or two ounces are required. It is an ingredient in Elect. e Caſſia, and Elect. e Senna, or lenitive electuary [a].

The leaves are ſometimes uſed in ſubacid infuſions; and Alpinus ſays, that a decoction of them kills the worms in children.

The fruit is frequently made an ingredient in punch, in the Weſt Indies; and mixed with a decoction of Borage, is reputed excellent in allaying the heat of urine [b].]

PROPAGATION AND CULTURE.

Sow the ſeeds on a hot-bed in the ſpring, and when the plants are come up, plant each in a ſeparate ſmall pot filled with light rich earth, and plunge them into a hot-bed of tanner's bark to bring them forward, obſerving to water and ſhade them until they have taken root; and as the earth in the pots appears dry, they muſt be watered from time to time, and ſhould have air given to them in proportion to the warmth of the ſeaſon, and the bed in which they are placed; when the pots in which they are planted are filled with their roots, the plants ſhould be ſhifted into pots of a larger ſize, which muſt be filled up with rich light earth, and again plunged into the hot-bed, giving them air, as before, according to the warmth of the ſeaſon; but in very hot weather the glaſſes ſhould be ſhaded with mats in the heat of the day, otherwiſe the ſun will be too violent for them through the glaſſes; nor will the plants thrive, if they are expoſed to the open air, even in the warmeſt ſeaſon; ſo that they muſt be conſtantly kept in the bark-ſtove both ſummer and winter, treating them as hath been directed for the Coffee-tree, with whoſe culture they will thrive exceeding well.

Theſe plants, if rightly managed, will grow very faſt; for I have had them upwards of three feet high in one ſummer from ſeed, and have had two plants which produced flowers the ſame ſeaſon they were ſown; but this was accidental, for none of the older plants have produced any flowers, although I have ſeveral plants of different ages, ſome of which are above twenty years old, and about fifteen feet high, with large ſpreading heads.

DESCRIPTIONS, &c.

1. The firſt ſort is a native of the ſouth of France, Spain, Italy, Ruſſia, Tartary, Barbary and Japan; where it grows to a tree of middling ſize, but in England is ſeldom more than fourteen or ſixteen feet high. The bark is rough, and of a dark brown colour; it ſends out many ſlender branches, moſt of which ſpread out flat and hang downward at their ends; theſe are covered with a cheſtnut-coloured bark, and garniſhed with very narrow finely divided leaves, which are ſmooth, of a bright green colour, and have ſmall leaves or indentures which lie over each other like ſcales of fiſh. The flowers are produced in taper ſpikes at the end of the branches, ſeveral of them growing on the ſame branch. The ſpikes are about an inch long, and as thick as a large earth-worm. The flowers are ſet very cloſe all round the ſpike; they are very ſmall, and have five concave petals of a pale fleſh colour, with five ſlender ſtamina terminated by roundiſh red anthers. The flowers appear in july, and are ſucceeded by oblong, acute-pointed, three-cornered capſules, filled with ſmall downy ſeeds, which ſeldom ripen in England.

[This

[a] Woodville. [b] Browne and Long.

Digitized by Google

[This ſpecies is eaſily diſtinguiſhed from the fourth, by the fineneſs of the leaves, and the flowers having only five ſtamens [c].

It is a very elegant tree, ſhading the banks of rivers, and is very much branched. The younger branches are filiform, denſe and panicled. Leaves glaucous, needle-ſhaped, very ſmall, imbricate, flowers white, ſmall in panicled ſpikes. Peduncles filiform. Calyx very ſmall, five-leaved [d].

Root branched, very hard. Trunk ſtraight, frequently the thickneſs of the wriſt, very much branched from the bottom, rod-like. Wood hard but ſpongy, brittle, with a yellowiſh ſap, within gray banded with ruſſet: bark teſtaceous, gray on the outſide. Younger branches herbaceous, ſlender, bright green, looſely imbricate with very ſmall, acute, alternate leaves. Spikes terminating the branchlets, copious, panicled, ſtraight, filiform; with flowers in cluſters, accompanied by a leaflet. Flowers ſubpeduncled, globulous, roſy-red, almoſt like thoſe of Heath. Calyx bell-ſhaped, coloured at the tips, three times ſhorter than the corolla. Corolla globular-bell-ſhaped. Filaments twice as long as the corolla. Germ conical, length of the corolla. The plant and flowers have ſcarcely any ſmell; but a ſubaſtringent taſte.

The Ruſſians and Tartars uſe a decoction of the twigs in the gout and rheumatiſm and contuſions of the limbs, as a fomentation; they alſo drink it in caſe of internal injury. They make handles for whips, &c. of the wood.

β. The large figure in Pallas's ſeventy-ninth plate, repreſents a ſingular variety, which occurs in the ſalteſt and drieſt parts of the Caſpian deſert. It is ſhrubby and a fathom high, tomentoſe-hoary and ſcaly, with the branchlets herbaceous, thicker, tomentoſe, the leaflets longer and hoary, more cloſely imbricate, and in all parts cloſer and thicker: but in the ſpikes and flowers very like the common ſort [e].

γ. Poiret and Desfontaines have found another variety of this in Barbary, with ſhorter thicker ſpikes, and with the flowers cloſer together on very ſhort peduncles: whereas in the true *gallica*, the ſpike is very long, thinner, and near the end of the branches: the flowers are a little ſeparate from each other [f].

Desfontaines's plant ſeems to be the ſame, though he does not refer to Poiret. He ſays that it differs from the *gallica*, in having the bark of the branches brown; the leaves more cloſely imbricate; the ſpike thicker; and the flowers twice or four times as large. He found it in Algiers on the coaſt.

Willdenow thinks that theſe may be diſtinct ſpecies.

Dr. Smith remarked the common ſort in very great plenty in Italy about Sinigaglia, and all along the hedges near the ſea, where the ſheep preferred it to every other food, never touching any other vegetable while that remained [g]. It was gathered in a wild ſtate on St. Michael's Mount, Cornwall, by Mr. Giddy; alſo by W. G. Maton, Eſq. and a ſpecimen of it preſented to the Linnean Society by him, december 2, 1794. He alſo found it near Hurſt-caſtle, Hants; and Dr. Goodenough near Haſtings, Suſſex.

2. This is a ſhrub, with round branches, ſquarroſe with permanent ſcales and ſheaths, ſubdivided and rod-like: branchlets filiform, ſcattered, jointed: joints margined at the top, and hollowed to receive the next joint. Scales in place of leaves from the margin of each joint, ovate acute alternate patulous. Spikes towards the ends of the branches, alternate, an inch and half long, imbricate, round. Bractes ovate, acute, ſpreading very much, permanent concave, length of the flowers. Calyx five-leaved, imbricate, with roundiſh leaflets. Corolla the ſame ſize as in T. gallica, with linear petals. Capſule four-cornered, pyramidal. Native of the Eaſt Indies and Arabia.—Linneus, not having ſeen the fructification, referred this ſhrub to the genus Thuja, from its habit [h].

Retzius obſerves, that there are at leaſt two ſpecies in India, different from the European ones, but that the ſpecimens he received were ſo much ſpoiled, that he could not aſcertain them. This perhaps may be one [i].

3. Found by Pallas in Siberia, in ſalt places of Songaria.]

4. This is rather a ſhrub than a tree, having ſeveral woody ſtalks ariſing from the ſame root, which grow quite erect, ſending out many ſide branches which are alſo erect; they have a pale-green bark when young, afterwards changing to a yellowiſh colour. The leaves are ſhorter, and ſet cloſer together than thoſe of the firſt ſort, and are of a lighter green approaching to a gray. The flowers are produced in long looſe ſpikes at the end of the branches, ſtanding erect: they are larger than thoſe of *gallica*, and have ten ſtamens ſtanding alternately.

[Allione thus diſtinguiſhes the firſt ſpecies and this. In that the leaves are much ſmaller, more cloſely imbricate, green and ſharper, in this they are glaucous-cinereous. In *germanica* the flowering-branches are ſtraight; but in *gallica* they are horizontal, or perpendicular to the ſtem. The flowers in *germanica* are twice as large and more, but on ſhorter peduncles than in *gallica*. The ſtamens in *germanica* are ten; the ſtigma ſimple; the ſtamens ſhorter than the petals, with twin whitiſh anthers: *gallica* has only five ſtamens, much longer than the petals, with purple anthers. The calyx in *germanica* appears to be compoſed of five linear green leaflets, with a ſingle leaf, not unlike the other leaves, ſupporting the peduncle; in *gallica* the leaf under each flower is whitiſh, pellucid, and awned; but the calyx ſeems to be compoſed of five very ſhort green leaflets placed imbricately. In *germanica* the ſtigma is orbicular, not trifid: in *gallica* the germ is purple with a trifid ſtigma.

Gærtner deſcribes the capſule as pyramidal; the ſeeds oblong or ovate, ſlightly compreſſed, of a pale rufeſcent colour, terminated by branched white ſtiped hairs; the receptacle a raiſed line, marked along the middle of the inſide of the valves, towards the baſe ending in a ſpongy lamina, to which the ſeeds are faſtened all round.

Native of Germany, by the banks of the Rhine and Danube, in Norway, Dauphiné, Spain, Piedmont, and the mountains of Dauria and Caucaſus in the Ruſſian empire.

Both ſpecies appear in the catalogue of Gerarde's garden, 1596. But Camden, in his life of Eliſabeth, ſays that the Tamariſk was introduced by Archbiſhop Grindall, as a ſpecific in diſorders of the ſpleen: and in the Remembrances for Maſter S. by R[d]. Hakluyt, 1582, we are told, that the Archbiſhop of Canterbury, Grindall, after he returned out of Germany, brought into this realm the plant of Tamariſke from thence, and this plant he hath ſo increaſed, that there be here thouſands of them; and many people have received great health by this plant [k]. Grindal was conſecrated to the Biſhoprick of London in december 1559, ſoon after his return from Germany.

Tamariſk, eſpecially this ſpecies, is ſometimes uſed abroad in obſtructions of the lower viſcera, and eſpecially in diſeaſes of the ſpleen. By combuſtion it yields no inconſiderable quantity of a fixed ſalt, which is diuretic and aperitive, and approaches to Glauber's ſalt. The bark of the root is the moſt efficacious part of the plant. A decoction of this is given in doſes of two to ſix drams, or even an ounce: of the wood and leaves double that quantity may be taken [l].

β. The variety figured by Pallas, is remarkable for having an herbaceous ſtem. It is found near the ſhore of the Caſpian ſea, on the Perſian ſide.

Loureiro has a ſpecies, which he names *Tamarix chinenſis*, from its being a native of China, which he ſays agrees with the *gallica* in having five ſtamens; but differs in having alternate leaflets, nodding branchlets, and erect terminating petals. It ſeems rather to agree with T. orientalis, *Tournef. cor.* 45. and *Forſk. arab.* 206. but it is not like that in all reſpects. Willdenow thinks it may poſſibly be the ſame with the *articulata* of Vahl.]

PROPAGATION AND CULTURE.

The Tamariſks may eaſily be encreaſed either by laying down their tender ſhoots in autumn, or by planting cuttings in an eaſt border, which will take root in a ſhort time, if they are ſupplied with water in the ſpring before they begin to ſhoot in dry weather; but they ſhould not be removed until the following autumn, at which time they may be either placed in a nurſery to be trained up two or three years, or elſe where they are deſigned to remain, obſerving to mulch their roots, and water them according as the ſeaſon may require, until they have taken root; after which, the only culture they will require, is to prune off the ſtraggling ſhoots, and keep the ground clean about them.

[The increaſing by layers is not only unneceſſary trouble, ſince cuttings grow very readily; but it is alſo a bad way, becauſe they very often will not ſtrike at all. The cuttings ſhould be of the laſt ſummer's ſhoot, and a moiſt border is moſt proper for them. In two years they will be good plants for the ſhrubbery, and may be planted out in almoſt any ſoil, though they like a light moiſt earth beſt, eſpecially the German ſort which grows naturally in low watery grounds*.

DESCRIPTIONS, &c.

1. [Root very large, tuberous, blackiſh externally, whence its old latin and engliſh names. Stems ſmooth, twining about every thing in their way, and thus aſcending without the aid of tendrils, to the height of ten or twelve feet in hedges or among buſhes, which their feſtoons of tawny leaves and red berries decorate in autumn. Leaves alternate, petioled, ſmooth and ſhining, quite entire, the nerves raiſed beneath, varying from kidney to heart-ſhaped, heart-ſpear-ſhaped, triangular ſpear-ſhaped, and even halbert-ſhaped. Flowers greeniſh, in long racemes or bunches from the ſide of the ſtalks, appearing in june, the barren and fertile ones on ſeparate roots, which Mr. Goodyer (in Ger. emac.) ſeems firſt to have noted. The male flowers ſoon fall off; but the female flowers are ſucceeded by ovate ſmooth berries. Theſe are inſipid. The root is acrid, and its pulp ſcraped has been formerly uſed as a ſtimulating plaiſter. The young ſhoots are ſaid to be good eating, when dreſſed like Aſparagus. The Moors eat them boiled with oil and ſalt*.

Native of Europe, but not in the north, in ſhady thickets, hedges and woods; alſo of the Levant, and about Algiers, in hedges.—It is called, wild Vine, and our Ladies ſeal. The latter name is from the French, *le ſceau de la Vierge.*]

2. This has a rounder root than the other; the ſtalks twine in the ſame manner; but the principal difference conſiſts in the leaves being divided into three lobes. It was diſcovered in the iſland of Crete or Candia by Tournefort, who ſent the ſeeds to the Royal Garden at Paris.

[Gerard (in Flora Gallo-Provinc.) obſerves, that the common ſort in the ſhade acquires broader greener leaves, ſinuate and even-three-lobed; and in this ſtate appears to be the ſame with Tournefort's plant, upon a compariſon of it with his ſpecimens.]

PROPAGATION AND CULTURE.

1. Sow the ſeeds ſoon after they are ripe under the ſhelter of buſhes, where, in the ſpring, the plants will come up, and require no farther care. The roots will abide many years.

2. This alſo is an abiding plant, hardy enough to live in the full ground in England; and it may be increaſed like the other.

DESCRIPTIONS, &c.

1. This riſes with a branching ſhrubby ſtalk, three or four feet high. The ſegments of the leaves are very narrow, and frequently cut into acute ſegments. The flowers are produced in ſmall roundiſh bunches, at the ends of the branches: they are of a bright yellow, and appear in auguſt.

Native of the Cape of Good Hope. [Cultivated by Mr. Miller in 1759[a].

2. Leaves linear, pinnate: pinnas linear, filiform, often bifid or trifid, quite entire. Corymb terminating and others axillary, few-flowered: flowers yellow[b].] Root fibrous perennial. Stalks more than two feet high. It flowers in june and july, and the ſeeds ripen in autumn.—Native of Siberia. [Cultivated by Mr. Miller in 1759.

3. This is a perennial hoary fine-leaved plant, with yellow flowers turned upwards.—Native of the Levant[c].

4. This is an annual plant, having the appearance of Chamomile. Stem half a foot high: branches the length of the ſtem aſcending, ſpreading a little. Leaves ſmall, pinnatifid; with ſeven or nine teeth, lanceolate, unarmed, acuminate, oppoſite. Flowers at the ends of all the branches, nine to twelve, unequally pedunculed and pedicelled, ſubglobular, yellow. Calyx ten-leaved; leaflets elliptic, looſe, almoſt equal; by no means imbricate. Corollas globular: corollets five-cleft.—Native of the Cape of Good Hope.

5. This is an annual plant, riſing about two feet high. Stem ſtiff, but herbaceous, ſending out many ſide branches their whole length; the lower ones four or five inches long, gradually ſhorter to the top. The leaves come out in ſmall cluſters from the joints: they are very narrow and ſhort; ſome end in three points, others are ſingle. The branches are terminated by cluſters of flowers of a bright yellow; each corymb on a ſhort peduncle. They appear in july or auguſt, and continue till the froſt deſtroys them, but the ſeeds do not ripen in England. The whole plant has a fine aromatic ſcent[d].

Linneus remarks, that the branches are longer than the primary umbel, and divaricating; the leaves linear, pinnate-five-cleft and trifid: and that it differs from its congeners in the want of a female ray, from Athanaſia in having no chaffs.—Native of Spain and Italy. Cultivated in 1758 by Mr. Miller[e].

6. This alſo is an annual plant. Leaves bipinnate, radical, numerous, length of a finger, like thoſe of Achillea Millefolium. Stems few, upright, ſtiffiſh, ſomewhat villoſe. Stem-leaves few, petioled, tooth-pinnate. Flower terminating, peduncled. Calyx oblong, imbricate, pubeſcent. Corolla yellow. Seeds and receptacle naked. Others decumbent, aſcending, longer, diffuſed ſtems ariſe afterwards from the root, terminated by a one-flowered peduncle[f].—Native of the Levant, where it was found by Forſkahl.]

7. Common Tanſy has a fibrous creeping root, which will ſpread to a great diſtance. [The herb is bitter, and has a ſtrong aromatic ſmell. Stems upright, two feet high,] in a garden from two to almoſt

[a] Hort. kew. [b] Linn. ſpec. [c] Tournef. cor.

[g] Linn. mant.

Digitized by Google

four feet, [leafy, round, ſtriated, ſcarcely hairy. Leaves alternate, deep green, acutely cut, ſmooth, or ſomewhat hairy beneath, eared at the baſe, embracing; pinnules lanceolate deeply and acutely ſerrate. The flowers are in terminating corymbs, of a golden colour and flattiſh. Calyx-leaves obtuſe, ſcarioſe at the edge. Florets very numerous, moſtly five-cleft, the marginal ones only female and trifid [a]. Linneus remarks, that the ray (in Sweden) appears only in a hot ſummer.—Seeds ſmall, uniform, inverſely pyramidal, pentagonal, ſubcinerious, with a pale rib at the corners. Down margined, narrow, membranaceous, pentagonal, indiſtinctly five-toothed, of a pale whitiſh colour [b].

Native of Europe and Siberia, in high meadows and paſtures, on the banks of rivers and in ſwampy places; flowering from june to auguſt.

According to Bergius, Tanſy is tonic, ſtomachic, anthelmintic, emmenagogue and reſolvent: qualities uſually attributed to bitters of the warm or aromatic kind, ſuch as ſeveral of the genus Artemiſia. Tanſy has been much uſed as a vermifuge, not only the leaves, but the ſeeds have been ſubſtituted with this intention for Santonicum. We are told by Dr. Clark, that in Scotland Tanſy was found to be of great ſervice in various caſes of gout; and Dr. Cullen ſays, "I have known ſeveral who have taken it without any advantage, and ſome others who reported that they had been relieved from the frequency of the fits.

Tanſy is alſo recommended in the hyſteria, eſpecially when this diſeaſe is ſuppoſed to proceed from menſtrual obſtructions.

This plant may be given in powder to the quantity of a dram or more, for a doſe; but it has been more commonly taken in infuſion, or drank as tea [c].

The tender leaves are ſometimes uſed to give a colour and flavour to puddings. The Finlanders obtain a green dye from it. Cows and ſheep eat it: horſes, goats and ſwine refuſe it. If a dead animal ſubſtance be rubbed with this plant, the fleſh fly will not attack it [d].]

There are three varieties, one with a curled leaf, which is called double Tanſy by gardeners; another with variegated leaves; and a third with larger leaves, which have little ſcent. [Ray informs us, that the variety with curled leaves was firſt obſerved in England.]

8. Roots hardy, fleſhy and creeping. Lower leaves near three inches long, and an inch and half broad, of a grayiſh colour, and on long foot-ſtalks. The ſtems riſe from two to three feet high, and ſend out branches from the ſide: the leaves on theſe are like the lower ones, but ſmaller and ſeſſile. The flowers are produced at the top of the ſtems in a looſe corymb; they are naked, and of a deep yellow colour, appear in auguſt, but are not ſucceeded by ſeeds in England. The whole plant has a ſoft pleaſant odour. It is a native of the South of France, Spain and Italy; and was formerly pretty much uſed in the kitchen and in medicine. [It is more aromatic, and has a pleaſanter ſmell than common Tanſy. It was called *Balſamita* from its balſamic quality. *Coſtus* from the greek Κοστος, an aromatic ſhrub: hence, and from its being put into ale, our old Engliſh name *Ale-coaſt*. *Coſtmary* is the Virgin Mary's Coſtus.—It was cultivated here in 1568, as appears from Turner's herbal [e].

9. All the florets are hermaphrodite and five-cleft; but having a naked, not a chaffy receptacle it agrees rather with this genus than Athanaſia [f].—Native of the Cape of Good Hope, where it was found by Mr. Francis Maſſon, and introduced in 1774. It flowers from may to auguſt [g].]

PROPAGATION AND CULTURE.

1. This and the other ſorts from the Cape muſt be kept in pots, and removed into ſhelter before hard froſts come on. They are eaſily increaſed by cuttings, planted in a bed of loamy earth, during any of the ſummer months. Shade them until they have taken root, and frequently refreſh them with water. When they have good roots, take them up with balls of earth, and plant them in pots; placing them among other hardy exotic plants, where they may remain till late in October, when they muſt be put into ſhelter. Theſe plants are ſo hardy as only to require protection from hard froſt, in mild weather therefore they ſhould be as much expoſed to the air as poſſible, to prevent their drawing up weak.

[5. Is propagated by ſeeds, and is hardy enough to bear the open air.]

7. Common Tanſy is eaſily propagated by the creeping roots, which, if permitted to remain undiſturbed, will in a ſhort time overſpread the ground. The ſlips therefore ſhould be placed at leaſt a foot aſunder, and in beds where the paths round them may be often dug, to keep their roots within bounds. They may be tranſplanted either in ſpring or autumn, and will thrive in almoſt any ſoil or ſituation.

If Tanſy ſhould be wanted early in the ſpring, a gentle hot-bed ſhould be made in december, and the old roots planted thereon without dividing them; arching the beds with hoops, and covering it with hoops in cold weather.—The ſecond ſort is propagated in the ſame way.

8. This alſo is propagated eaſily by parting the roots, in autumn. Where it is planted for uſe, the ſlips ſhould be ſet in beds at two feet diſtance every way: in two years the roots will meet, every other year therefore they ſhould be parted and tranſplanted, to keep them within compaſs. They will thrive in almoſt any ſoil or ſituation, but will continue longeſt in dry land.

has ſupplied it in a peculiar manner with tendrils: for the leaves, which are always three on every common footſtalk towards the root, are never more than two at the top, but the extremity of the common ſtalk, which generally holds the third leaf in the lower branches, ſhoots here into a long winding tendril, by which it holds and ſticks to every twig or branch it meets. This climbing plant is frequent in many parts of the iſland of Jamaica, but ſeems moſt common between St. Elizabeth's and Weſtmoreland.

2. This weakly plant ſuſtains itſelf generally by the help of the neighbouring trees, or is found ſpreading upon the ground, where it does not meet with a ſupport. Its ſtem is moderately thick, and ſtretches frequently about ſeven or eight feet from the root. The leaves are thick and ſhining; the fruit round and ſmooth. It is found, in Jamaica, about Port Antonio, near the caſcade in St. Ann's, and in many parts of the mountains, eſpecially thoſe between Sixteen-mile-walk and Luidas.[f]

TANARIUS. See *Ricinus*.

TANDELA-COTTI. See *Crotalaria juncea*.]

TANNERS BARK is the Bark of the Oak-tree, chopped or ground into coarſe powder, to be uſed in tanning or dreſſing of ſkins, after which it is of great uſe in gardening: firſt, by its fermentation (when laid in a proper quantity,) the heat being always moderate, and of a long duration, which renders it of great ſervice for hot-beds; and ſecondly, after it is well rotted, it becomes excellent manure for all ſorts of cold ſtiff land, upon which one load of Tan is better than two of rotten dung, and will continue longer in the ground.

The uſe of Tan for hot-beds has not been many years known in England. The firſt hot-beds of this ſort, which were made in England, were at Blackheath in Kent, above fourſcore years ago; theſe were deſigned for the raiſing of Orange-trees, but the uſe of theſe hot-beds being but little known at that time, they were made but by two or three perſons, who had learned the uſe of them in Holland and Flanders, where the gardeners ſeldom make any other hot-beds; but in England there were very few hot-beds made of Tanners Bark before the Ananas plants were introduced into this country, which was in 1719, ſince which time the uſe of theſe hot-beds has been more general, and are now made in all thoſe gardens where the Ananas plants are cultivated, or where there are collections of tender exotic plants preſerved; and the gardeners here are now better ſkilled in the making and managing of theſe hot-beds than in moſt other countries, which might render it leſs neceſſary to give a full deſcription of them here; but yet, as there may be ſome perſons in the remote parts of England, who have not had an opportunity of informing themſelves of the uſe of Tanners Bark for this purpoſe, I ſhall inſert the ſhorteſt and plaineſt method of making and managing theſe hot-beds, as it is practiſed by the moſt knowing perſons who have long made uſe of theſe hot-beds; and firſt, I ſhall begin with the choice of the Tan.

The tanners in ſome parts of England do not grind the Bark to reduce it into ſmall pieces, as is commonly practiſed by the tanners near London, where there is great difference in the ſize of the bark, ſome being ground much ſmaller than the other, according to the different purpoſes for which it is intended; but in many places the Bark is only chopped into large pieces, which renders it very different for the uſe of hot-beds; for if the Tan is very coarſe, it will require a longer time to ferment than the ſmall Tan; but when it begins to heat, it will acquire a much greater degree, and will retain the heat a much longer time than the ſmall; therefore where there is choice, the middling ſized Tan ſhould be preferred, for it is very difficult to manage a hot-bed when made of the largeſt Tan; the heat of which is often ſo great, as to ſcald the roots of plants, if the pots are fully plunged into the bed; and I have known this violent heat continue upward of two months, ſo that it has been unſafe to plunge the pots more than half their depth into the Tan, till near three months after the beds have been made; therefore where the perſons, who have the care of theſe beds, do not diligently obſerve their working, they may in a ſhort time deſtroy the plants which are placed in the beds: on the other hand, if the Tan is very ſmall, it will not retain the heat above a month or ſix weeks, and will be rotten and unfit for a hot-bed in a ſhort time; ſo that where the middle-ſized Tan can be procured, it ſhould always be preferred to any other.

The Tan ſhould be always ſuch as has been newly taken out of the pits, for if it lies long in the tanners yard before it is uſed, the beds ſeldom acquire a proper degree of heat, nor do they continue their heat long; ſo that when it has been more than a fortnight or three weeks out of the pit, it is not ſo good for uſe as that which is new. If the Tan is very wet, it will be proper to ſpread it abroad for two or three days, to drain out the moiſture, eſpecially if it is in autumn or winter ſeaſon, becauſe then, as there will be little ſun to draw a warmth into the Tan, the moiſture will prevent the fermentation, and the beds will remain cold; but in the ſummer ſeaſon, there is no great danger from the moiſture of the Tan. The heat of the ſun through the glaſſes will be then ſo great, as ſoon to cauſe a fermentation in the Tan.

Theſe Tan-beds ſhould be always made in pits having brick-walls round them, and a brick pavement at the bottom, to prevent the earth from mixing with the Tan, which will prevent the Tan from heating. Theſe pits muſt not be leſs than three feet deep, and ſix feet in width, but ſeven is better; the length muſt be in proportion to the number of plants they are to contain, but if they are not ten feet in length, they will not retain their heat long; for where there is not a good body of Tan, the outſide of the bed will ſoon loſe its heat, ſo that the plants which are there plunged, will have no benefit of the warmth, nor will the middle of theſe beds retain their heat long, ſo that they will not anſwer the purpoſe for which they are intended.

When the Tan is put into the bed, it muſt not be beaten or trodden down too cloſe, for that will cauſe it to adhere, and form one ſolid lump, ſo that it will not acquire a proper heat; nor ſhould it be trodden down at the time when the pots are plunged into the beds, to avoid which there ſhould be a board laid croſs the bed, which ſhould be ſupported at each end, to prevent its reſting upon the Tan, upon which the perſon ſhould ſtand who plunges the pots, ſo that the Tan will not be preſſed down too cloſe. When the Tan is quite freſh, and has not been out of the pits long enough to acquire a heat, the beds will require a fortnight, or ſometimes three weeks, before they will be of a proper temperature of warmth to receive the plants; but in order to judge of this, there ſhould be three or four ſticks thruſt down into the Tan, about eighteen inches deep, in different parts of the bed, ſo that by drawing out the ſticks, and feeling them at different depths, it will be eaſy to judge of the temper of the bed; and it will be proper to let a few of theſe ſticks remain in the bed after the plants are plunged, in order to know the warmth of the Tan, which may be better judged of by feeling theſe ſticks, than by drawing out the pots, or plunging the hand into the Tan.

When the Tan is good, one of theſe beds will retain a proper degree of heat for near three months; and when the heat declines, if the Tan is forked up and turned over, and ſome new Tan added to it, the heat will renew again, and will continue two months longer; ſo that by turning over the Tan, and adding ſome new Tan every three months or thereabouts, as the bed is found to decline of its heat, they may be continued one year, but every autumn it will be proper to take out a good quantity of the old Tan, and to add as much new to the bed, that the heat of the bed may be kept up in winter; for if the heat is ſuffered to decline too much during the cold ſeaſon, the plants will ſuffer greatly; to prevent this, there ſhould always be ſome new Tan added to the bed in winter, when

[f] Browne.

Digitized by Google

when the heat is found to decline; but the Tan ſhould be laid in a dry place a week or ten days to dry, before it is put into the bed, otherwiſe the moiſture will chill the old Tan in the bed, and prevent the fermentation; ſo that unleſs the Tan is turned over again, there will be little or no heat in the beds, which often proves fatal to the plants which are plunged in them; therefore whoever has the management of theſe beds, ſhould be very careful to obſerve conſtantly the warmth of the Tan, ſince, upon keeping the beds in a due temperature of warmth, their whole ſucceſs depends; and where this caution is not taken, it frequently happens that the Ananas plants run into fruit very ſmall, or the plants are infected by inſects, both which are occaſioned by the growth of the plants being ſtopped by the decline of the heat of the Tan; therefore great regard muſt be had to that, eſpecially in winter.

The great advantages which theſe Tan-beds have of thoſe which are made of horſe-dung, are the moderate degree of heat which they acquire, for their heat is never ſo violent as that of horſe-dung, and they continue this heat much longer; and when the heat declines, it may be renewed, by turning the beds over, and mixing ſome new Tan with the old, which cannot be ſo well done with horſe-dung; and likewiſe the beds will not produce ſo great ſteams, which are often injurious to tender plants, ſo that theſe Tan-beds are much preferable to thoſe of horſe-dung for moſt purpoſes.

Tan, when it is well rotted, is alſo an excellent manure for all cold and ſtiff lands; and if it is laid upon Graſs ground in autumn, that the rains in winter may waſh it into the ground, it will greatly improve the Graſs; but when it is uſed new, or in the ſpring of the year, when dry weather comes ſoon after, it is apt to cauſe the Graſs to burn, which has occaſioned the diſuſe of Tan in many places; but if properly uſed, it will be found an excellent dreſſing for all ſtiff lands.

[It may be agreeable to thoſe who live where there are plenty of Oaks, and yet perhaps at a diſtance from tanners, to be informed that Oak leaves anſwer very well the purpoſe of Tan in hot-houſes.

Being raked into heaps, carry them to ſome place near the hot-houſe; fence them with hurdles, or any thing elſe, to keep them from being blown about; tread them well, and water them if they are brought in dry. Make the heap ſix or ſeven feet thick, and cover it with mats. In a few days the heap will come to a ſtrong heat; in five or ſix weeks they will be properly prepared for the hot-houſe. In getting them into the Pine-pits, if they appear dry, water them again; and tread them well, till the pits are quite full. Then cover the whole with Tan two inches thick, and tread it till the ſurface becomes ſmooth and even. On this place the Pine-pots, beginning with the middle row firſt, and filling up the ſpaces between the pots with tan, as when tan only is uſed.

The leaves will retain a conſtant and regular heat for twelve-months without ſtirring or turning. After this the Pines will have no occaſion to be moved, except when their pots are to be ſhifted, &c. when a little freſh Tan ſhould be added. Without a covering of Tan, the leaves by their caking will be apt to ſhrink from the ſides of the pots, and let the heat eſcape.

Oak leaves are ever preferable to Tanner's Bark; for they always heat regularly and conſtantly, never heating with violence, or turning cold after the furious heat is gone off: there is a ſaving in point of expence; and the decayed fermented leaves make good garden manure; whereas rotten Tan is of no value, for that purpoſe.

Leaves mixed with dung make excellent hot-beds, preſerving their heat much longer than when made from dung only[t].

Lin. ſyſt. 740. *ſuppl.* 360.

Leaves aceroſe, calyxes four-leaved.]

DESCRIPTIONS, &c.

1. Stem ſtrong, woody, riſing to the height of twelve or fourteen feet, ſending out many woody branches at the top, which may be trained to a regular head. Leaves in ſhape like thoſe of the broad-leaved Sallow, having a downy ſurface like Sage, and their under ſides white; in ſmell they reſemble Roſemary leaves when bruiſed. The flowers are produced in ſpikes at the extremity of the ſhoots, and being of a dull purple colour, do not make any great appearance. They appear in autumn, and continue great part of the winter. It retains the leaves all the year.

[Receptacle flattiſh, villoſe, with the hairs ſhorter than the calyx. Seeds ſmall, ovate, woolly, crowned with the permanent corollet, woolly on the outſide and continuous with the external integument of the ſeed. No down except a copious wool common to the ſeed and corollet. Bergius is miſtaken in attributing

Digitized by Google

buting a ſuperior germ to the flower; and Linneus in aſſigning a feathered down to the ſeeds[b].

Native of the Cape of Good Hope; alſo of China, according to Miller.—Cultivated 1690, in the Royal garden at Hampton Court.

2. This reſembles the preceding very much, but is void of ſmell, and entirely ſmooth all over. It varies with wider and narrower, entire and toothed leaves.

3. This is a ſtiff branching ſhrub, ſeldom attenuated at the top. Leaves like thoſe of Heath, cluſtered, linear, very ſhort. Flowers cluſtered, lateral, bigger than the leaves, on ſhort peduncles. Calyx-leaves oval. Corollas few, minute, concealed within the ſnow-white down of the receptacle, which is much larger than the flower.

Theſe are both natives of the Cape of Good Hope[i].]

PROPAGATION AND CULTURE.

Theſe plants are too tender to live through the winter in the open air in England, but requiring no artificial heat, may be placed with Myrtles, Oleander, &c. in winter, and in ſummer may be expoſed to the open air in a ſheltered ſituation.

They may be increaſed by cuttings, planted in may, in pots filled with light earth, and if they are plunged into a moderate hot-bed, it will promote their putting out roots; ſcreen them from the ſun until they have taken root, which will be about the middle of july; when each ſhould be tranſplanted into a ſeparate pot, and placed in the ſhade until they have taken new root: after which ſet them with other hardy exotic plants in a ſheltered ſituation to the middle or end of october, when they ſhould be removed into the greenhouſe, placing them where they may have a large ſhare of air in mild weather. Being very thirſty plants, they muſt be often watered. They muſt be ſhifted every year, and as they increaſe in ſize, into larger pots.

DESCRIPTION, *&c.*

Not larger than the finger nail. Green not pellucid, rough with white riſing dots. Leaf cordate-lanceolate, at firſt green, afterwards dark purple, blackiſh underneath. Fructification at the end, on the under ſide, the ſize of a Vetch. Calyx black; opening, containing the fruit covered with a yellowiſh ſkin, and filled with a yellowiſh pulp which rubs to powder between the fingers, and ſtains them[k].

Native of Italy, Spain, Conſtantinople, Flanders, Saxony about Dreſden, and England near Dawliſh in Devonſhire: flowering from march to may.

DESCRIPTIONS, *&c.*

1. Trunk ſtraight, with a ſmooth deciduous bark. Wood very hard, tough, and of a fine grain. Leaves thickly ſet, linear, ſmooth, evergreen. Flowers axillary, enveloped with imbricate bractes: the male on one tree, ſulphur-coloured, without a calyx; the female on another, with a ſmall green calyx, ſuſtaining the oval flattiſh ſeed, which calyx at length becomes red, ſoft, full of a ſweet ſlimy pulp[l].

The ſingular fructification of this tree is differently deſcribed. According to Gærtner, the calyx is imbricate with four or ſeven rounded, concave ſcales. The receptacle in the male is elongated into a column, to which are faſtened about ten anthers, after they open becoming lobed and peltate:—in the female, firſt orbicular, narrow, fungoſe; then ſubhemiſphe-

rical, membranaceous; finally fleſhy, berried, ſcarlet. Pericarp a bony obovate nut, mucronate at the tip, of a turgid lenticular form, ſmooth, dark-coloured, one-celled, valveleſs, involucred with the receptacle of the flower enlarged, ovate-globular, pervious at the tip, fleſhy and ſcarlet. Seed of the ſame ſhape with the cavity of the nut, but with a mamillary proceſs at the baſe, pale.

The fruit in ſome degree reſembles a ſmall acorn whilſt it is young, but as it advances, the ſcarlet cup becomes more fleſhy, and is elongated till it covers the whole ſeed or nut, except a round hole at the tip.]

Mr. Miller aſſerts, that though the male and female flowers are commonly on different trees, yet they are ſometimes found upon the ſame. I have never obſerved this, but it is not improbable.

The Yew-tree is a native of Europe, North America, [and Japan. Its proper ſituation is in mountainous woods, or more particularly the cleſts of high calcareous rocks. Cæſar mentions the *Taxus* as very common in Gaul and Germany. England formerly poſſeſſed great abundance, and it is now not very uncommon in a wild ſtate, in ſome parts of the country. Of planted trees there are yet many in church-yards. In Ireland, it was evidently very plentiful in former times, being at preſent common in a foſſil ſtate, but it is not now found there except in cultivation [m].

The Yew, ſays Mr. Gilpin, is a pure native of Britain: and Mr. Pennant informs us, that it is to be found wild upon the hills that bound the waters of the Winander, and on the face of many precipices of different places in this kingdom [n].

Mr. Lightfoot ſays, that it is found here and there in the Highlands of Scotland in a truly wild ſtate.

In ſome parts of Buckinghamſhire it comes up in great abundance from the berries ſpontaneouſly.

The accounts of large Yew-trees yet remaining in England are numerous.

Mr. Lyſons mentions one in the church-yard at Totteridge, the girth of which, at three feet from the ground, is twenty-ſix feet: and another in Woodford church-yard, which girths at the ſame height eleven feet nine inches; and at four feet and a half from the ground fourteen feet three inches: the ſpread of its boughs forms a circumference of about one hundred and eighty feet [o].

At Waltham in Eſſex, were two large Yew-trees in which they uſed to hang the bells.

There is one of an extraordinary ſize at Peterſham: and another with a thick and ſturdy trunk at Lord Newberry's, in the old palace garden at Richmond, planted three days before Queen Elizabeth was born.

The aged Yew groves at Mickleton in Surrey could not eſcape the notice of Mr. John Toland, in his pleaſant deſcription of Epſom, 8vo. 1711.

Mr. Evelyn ſays, "he that in winter ſhould behold ſome of our higheſt hills in Surrey, clad with whole woods of theſe trees (the Box and the Yew) for divers miles in circuit, as in thoſe delicious groves of them, belonging to the late Sir Adam Brown of Bech-worth caſtle, from Box-hill, might eaſily fancy himſelf tranſported into ſome new or enchanted countrey [p]."—Theſe woods and groves are now no more.

The ſame author mentions "a Yew-tree in the church-yard of Crowhurſt in Surrey, which was ten yards in compaſs. Another in Braburne church-yard, not far from Scots-Hall in Kent, which being fifty-eight feet eleven inches in circumference, will bear near twenty-feet diameter: not to mention the goodly planks, and other conſiderable pieces of ſquared and clear timber, which had been hewed and ſawn out of ſome of the arms only torn from it by impetuous winds. Such another monſter is alſo to be ſeen in Sutton church-yard near Wincheſter [q].

Several fine old trees are to be ſeen on ſome ſandy rocks about two miles from Withyam, and five from Tunbridge [r].

Near the church at Hedſor in Bucks, is a fine growing Yew-tree, which meaſures twenty-ſeven feet circumference [s]. There are other large trees on the chalk hills of the ſame county: and a ſhady walk of them in the garden of Bradenham houſe near Weſt Wycombe, the branches of which would make excellent bows.

At Mill Hill, Hendon, in Middleſex, are four beautiful Yew trees. Dr. Trinder, whoſe property they are, favoured me with the following account of them on the 20th of April, 1797.—"Their poſition is nearly rhomboidal, in a little field belonging to me, in ſize about two acres and a half, and near the ten mile ſtone from London. The tradition is, that there were many more Yews in this field, which ſeems probable from the hollows that appear therein. I meaſured them this morning round the ſound and ſolid wood. The trees are in good preſervation, ſhowing but ſmall ſymptoms of decay.

N° 1. in girth 9 feet.
2. —— 8 feet.
3. —— 7½ feet.
4. —— 7 feet.

An apprehenſion that Dr. Trinder had an intention of felling thoſe magnificent and venerable trees, attracted the attention of the late Michael Collinſon, and induced him to write a feeling letter to the learned and benevolent proprietor in their behalf.

Other remarkable Yews that are mentioned are, Sir Francis Vincent's at Stoke. One at Iſley by Oxford, four yards and ſix inches round. Talbot's Yew in Takerſley pariſh. One in Martley church-yard, Worceſterſhire, about twelve yards in circumference. In the church-yard at Aſhill in Somerſetſhire are two very large Yew-trees; one fifteen feet round, with a vaſt ſpread of branches, extending N. and S. fifty-ſix feet. The other divides into three large trunks juſt above the ground, but many of the arms are decayed [t]. Two trees are now growing on the hill above Fountain's abbey, near Ripon, which in 1770 meaſured in circumference from thirteen feet to twenty-ſix feet ſix inches [u]. In the church-yard at Aberiſtwith are eleven Yew-trees, the largeſt twenty-four feet, and the ſmalleſt eleven and a half in circumference. In Mamkilad church-yard are twelve fine trees, the largeſt of which is twenty-five feet in circumference [x]. Doubtleſs there muſt be many large ancient Yew-trees remaining in Wales.

Mr. Pennant mentions one in Fontingal church-yard, in the highlands of Scotland, the ruins of which meaſured fifty-ſix feet and a half in circumference. And Mr. Lightfoot informs us, that at Glenure, near Glen-Creran, in Upper Lorn, there are the remains of an old wood of Yew.

In Ireland, there is a Yew-tree at Macruſs Abbey, having one great ſtem, two feet in diameter, and fourteen feet high, with a vaſt head of branches ſpreading on every ſide, and filling the area of the cloiſters [y].

This catalogue might probably be much increaſed by a diligent reſearch into County hiſtories, and the works of travellers.

The comparative value of a Yew with other trees, in former times, may be ſeen from the following table, taken from the ancient laws of Wales.

A conſecrated Yew, its value is a pound.
An Oak, its value is ſix ſcore pence.
A Miſtletoe branch, its value is three ſcore pence.
Thirty pence is the value of every principal branch in the Oak.
Three ſcore pence is the value of a ſweet Apple-tree.
Thirty pence is the value of a ſour Apple tree.
Fifteen pence is the value of a wood Yew tree.
Seven pence halfpenny is the value of a Thorn tree.
Four pence is the value of every tree after that.

The great value ſet upon a conſecrated Yew, in the above table, in compariſon with a common tree of the ſame kind, induces me, among other reaſons to think, that the Yew was commonly planted in church-yards, rather from motives of ſuperſtition, than on account of its utility in making bows, as many have ſuppoſed: for a ſingle tree would have afforded a very ſcanty ſupply for this purpoſe. Our forefathers were particularly careful in preſerving this funereal tree, whoſe branches it was uſual to carry in ſolemn proceſſion to the grave, and afterwards to depoſit therein, under the bodies of their departed friends. Our learned Ray ſays, that our anceſtors planted the Yew in church-yards, becauſe it was an evergreen tree, as a ſymbol of that immortality which they hoped and expected for the perſons there depoſited. For the ſame reaſon this and other evergreen trees are even yet carried in funerals and thrown into the grave with the corpſe in ſome parts of England; and in Wales, planted, with flowers, upon the grave itſelf.

The wood of the Yew is red and veined, very hard and ſmooth, much uſed by turners, inlayers, and cabinet-makers. For cogs of mills, handles of tools, poſts to be ſet in moiſt grounds, and everlaſting axle-trees, there is none to be compared with it. It is likewiſe uſed for the bodies of lutes, &c., bowls, wheels, and pins for pullies, &c.[a]—ſpoons, cups, and flood-gates for fiſh-ponds, which hardly ever decay[a].

Formerly, ſays Mr. Gilpin[b], the Yew was, what the Oak is now, the baſis of our ſtrength. Of it the old Engliſh yeoman made his long-bow; which, he vaunted, nobody but an Engliſhman, could bend. In ſhooting he did not, as in other nations, keep his left hand ſteady, and draw his bow with his right: but keeping his right at reſt upon the nerve, he preſſed the whole weight of his body into the horns of his bow. Hence aroſe the Engliſh phraſe of *bending a bow*; and the French of drawing one.

So great was the demand for Yew in the days of archery, that our own ſtock could not ſupply the Bowyers, and they were obliged by ſtatute to import ſtaves of it for making Bows; ſometimes at a very high price.

By the 5th Edward IV. it was directed that every Engliſhmen in Ireland, and Iriſhmen dwelling with Engliſhmen, ſhall have an Engliſh bow of his own height, made of Yew, Wych, Hazel, Aſh, or Awburne (perhaps Alder[c].) But "as for Braſell (ſays Roger Aſcham) Elme, Wych and Aſhe, experience doth prove them to be but mean for bowes, and ſo to conclude, *Ewe* of all other things is that, whereof perfite ſhootinge would have a bowe made[d]."

All Venetian ſhips, with every butt of Malmſey or Tyre wine, were to import ten bow ſtaves, as the price had riſen from 40*s.* to 8*l.* a hundred.

33 Hen. VIII. c. 9. recites the great price of Yew bows made of Elke (probably Elbe) Yew; and reduces it to 3*s.* 4*d.*

By one of the ancient ſtatutes a bow of foreign Yew may be ſold for no more than 6*s.*

8 Eliz. c. 10. regulates the price of bows; and 13 Eliz. c. 14. enacts that bow ſtaves ſhall be brought into the realm from the Hanſe towns and the eaſtward.—From the end however of the reign of Hen. VIII. archery ſeems to have been chiefly conſidered as a paſtime[e].

Mr. Gilpin, contrary to general opinion, is a great admirer of the form and foliage of this tree. "The Yew, ſays he, is of all other trees, the moſt tonſile. Hence all the indignities it ſuffers. We every where ſee it cut and metamorphoſed into ſuch a variety of deformities, that we are hardly brought to conceive, it has a natural ſhape; or the power which other trees have, of hanging careleſsly or negligently. Yet it has this power in a very eminent degree; and in a ſtate of nature, except in expoſed ſituations, is perhaps one of the moſt beautiful evergreens we have:

[a] Evelyn. [a] Withering. [b] Foreſt ſcen. 1. 92. [c] Barrington in Archæologia, 7. 48, 53. [d] Works, ed. Benn. 133. [e] Archæol. 7. 54, 55, 61, 65.

We ſeldom however ſee the Yew in perfection. In the New Foreſt it formerly abounded: but it is now much ſcarcer. Still in many parts of the foreſt, ſome noble ſpecimens are left. One of theſe is a tree of peculiar beauty. It immediately divides into ſeveral maſſy limbs, each of which, hanging in grand looſe foliage, ſpreads over a large compaſs of ground, and yet the whole tree forms a cloſe compact body: that is, its boughs are not ſo ſeparated as to break into diſtinct parts. It cannot boaſt the ſize of many other trees on record, but it has ſufficient ſize for all the purpoſes of landſcape, and in point of picturesque beauty it probably equals any of them. It ſtands not far from the banks of Lymington river, and occupies a ſmall knoll, ſurrounded with other trees, ſome of which are Yews, but of inferior beauty. If ſuch trees were common, they would recover the character of the Yew among the admirers of pictureſque beauty[f].

Dr. Hunter mentions a variety with ſhort leaves which appears very ornamental in plantations.

It has been much debated whether the Yew-tree be poiſonous or not; there cannot now be any doubt of its being ſo. Mr. White in his hiſtory of Selborne, has given ſome authentic information on the ſubject, as well as on other particulars relative to this intereſting tree.

"In the church-yard of this village, ſays he, is a Yew-tree, whoſe aſpect beſpeaks it to be of a great age: the body is ſquat ſhort and thick, and meaſures twenty-three feet in the girth, ſupporting an head of ſuitable extent to its bulk. This is a male tree, which in the ſpring ſheds clouds of duſt, and fills the atmoſphere around with its farina. As far as we have been able to obſerve, the male trees become much larger than the females; and moſt of the Yew-trees in the church-yards of this neighbourhood are males; but this muſt have been matter of mere accident, ſince men, when they firſt planted Yews, little dreamed that there were ſexes in trees.

In a yard, in the midſt of the ſtreet, till very lately grew a middle-ſized female tree, which commonly bore great crops of berries. By the high winds uſually prevailing about the autumnal equinox, theſe berries, then ripe, were blown down into the road, where the hogs ate them. It was remarkable, that though barrow-hogs and young ſows found no inconvenience from this food, yet milch-ſows often died after ſuch a repaſt: a circumſtance that can be accounted for, only by ſuppoſing that the latter, being much exhauſted and hungry, devoured a larger quantity.

But the twigs and leaves of Yew, eaten in a very ſmall quantity, are certain death to horſes and cows, and that in a few minutes. An horſe tied to a yew-hedge, or to a faggot-ſtack of dead Yew, ſhall be found dead before the owner can be aware that any danger is at hand: the writer has been ſeveral times a ſorrowful witneſs to loſſes of this kind among his friends; and in the iſle of Ely had once the mortification to ſee nine young ſteers or bullocks of his own all lying dead in an heap from browzing a little on an hedge of Yew in an old garden, into which they had broken in ſnowy weather. Even the clippings of a Yew hedge have deſtroyed a whole dairy of cows when thrown inadvertently into a yard. And yet ſheep and turkies, and as park-keepers ſay, deer, will crop theſe trees with impunity.

Some intelligent perſons aſſert, that the branches of Yew, while green, are not noxious: but among the number of cattle that we have known fall victims to this deadly food, not one has been found, when it was opened, but had a lump of green Yew in its paunch. True it is, that Yew-trees ſtand for twenty years or more in a field, and no bad conſequences enſue: but at ſome time or other, cattle, either from wantonneſs when full, or from hunger when empty, will be meddling, to their certain deſtruction[g].

According to Linneus, horſes and cows refuſe the Yew, but ſheep and goats eat it. It ſhould ſeem that ſheep feed on it with impunity, ſince the lower part

[f] For. ſcen. p. 92, 93. [g] P. 324.

of

Digitized by Google

of the trees, in ſheep-walks where the boughs come near the ground, are as much formed into ſhapes by their browzing, as any other tree or ſhrub: it is however ſo common to find a ſheep dead, that the cauſe is ſeldom enquired into[h]. Sheep are ſaid to have been killed by eating the bark. It is a common notion, that the loppings in a withering or half dried ſtate are moſt detrimental to cattle[i]. This may be true, but yet it is certain from what has been ſaid above, that the freſh leaves are often fatal to them. And this contradicts the aſſertion of Theophraſtus, that ruminating animals eat Yew-leaves with impunity[k]. Though perhaps they are killed by them leſs frequently, and not ſo ſuddenly as horſes and aſſes, which by eating a handful or two of leaves from the extremities of the branches, have been known to die in a quarter of an hour after, ſuddenly, and without any apparent ſymptoms or pain, not diſtended by wind, nor inflamed. Some cows die in the ſame eaſy manner; but others vomit, are very ſick, and languiſh a long time. Six or eight ſheep periſhed by browzing on this tree. A horſe and a mule died by eating five ounces each of the leaves; the former, who took them faſting, died within an hour; the latter at the end of three hours, he had taken them after eating[l].

Yew-leaves are certainly fatal to the human ſpecies. Evelyn, from Aubrey, relates a caſe of two women who died from a drink of it: and Dr. Percival of Mancheſter mentions another of three children, who were killed by a ſpoonful of the green leaves, which was given them for worms: they died without agony or any of the uſual ſymptoms of vegetable poiſons. The ſame quantity of the dried leaves had been given the day before without any effect[m].

A clergyman, who was curate in Suſſex, informed me, that a young lady and her ſervant, his pariſhioners, being ſeized with an ague, were adviſed to take a decoction of Rue, which they unhappily miſtaking for Yew, ſent to the church-yard, where a large old tree grew, and gathered a quantity of the leaves, of which they made a decoction, and drank it upon going to bed. The next morning they were both found dead. This was ſunday: on the thurſday following, the clergyman was called upon to bury them: he performed the office on the ſervant, but the young lady had ſo fine a bloom on her countenance, that they entertained hopes of her being in a ſtate of ſuſpended animation, and accordingly tried the experiments uſual in ſuch caſes, but without ſucceſs: they determined however not to bury her at that time, but kept her till the enſuing ſaturday, and even then the corpſe remained totally unchanged. What made it more remarkable was, that the accident happened in november, and the weather was of that damp murky kind in which fleſh keeps the worſt.

Reſpecting the fruit, Theophraſtus ſays it is eaten by ſome perſons, being ſweet and harmleſs. The berries are certainly not ſo deleterious as the leaves; I was fond of ſucking them in my youth, but ſpit out the ſtones. The ſows, I preſume, mentioned by Mr. White, ſwallowed the whole fruit, and in large quantities. They are eaten by birds, after the haws are conſumed, or deſtroyed by froſt. Dioſcorides ſays they occaſion the flux: and that a drink of the leaves brings on a coldneſs of the whole body, ſuffocation and death in a little time. Cæſar, in his gallic war relates, that Cativulcus king of the Eburones killed himſelf by a draught of Yew.—Gerarde with his uſual ſimplicity relates, that when he was young, and went to ſchool, he and divers of his ſchool-fellows did eat their fills of the berries of this tree.

Mr. Boutcher aſſerts upon his own experience, that the wooden parts of a bed made of Yew, will not be approached by bugs.

An anonymous writer in the Gentleman's Magazine ſuggeſts that the Yew afforded branches for the proceſſions on Palm-Sunday. In the eaſtern counties, the children gather the branches of the Sallow, which is then in flower, and carry them about on that feſtival.]

The only uſe this tree is fit for in gardens, is to form hedges for the defence of exotic plants; for which purpoſe, when it is neceſſary to have hedges, it is the moſt proper of any; the leaves being ſmall, and the branches ſo cloſe together, that if carefully ſhorn, they break the winds better than any other ſort of fence, becauſe they are not reverberated, as they are againſt walls and pales. [But they have this diſadvantage, that they are a harbour for ſnails and other vermin.

If the only uſe of the Yew in gardens be for hedges: in plantations, notwithſtanding its ſombrous hue, it may be placed ſo as to be an ornament, among other evergreen trees; and where a diſagreeable object is to be concealed, nothing is more effectual than the Yew, which with proper care may be removed even when it is of a conſiderable ſize.

In the ſouth of England almoſt every church-yard has its tree, and ſome have two; but in the north few are to be found.

2. The fruit reſembles the acorns of the Oak, and is aſtringent. It is eaten in deſerts, is ſaid to be very wholeſome, and notwithſtanding its aſtringent taſte, to be laxative to the bowels. An oil expreſſed from it is uſed in cookery. The wood is in requeſt among the cabinet-makers.—Native of Japan, here and there near Nagaſaki and in Nipou.

3. Branches round, knotted from the fallen leaves, flexuoſe, erect, aſh-coloured, ſmooth. Leaves ſcattered, elliptic, entire with a thick rib, ſmooth, pale beneath, patulous, a finger's length. Flowers among the leaves, axillary, dioecous. Ament male, cylindric. Berry ovate, ſmooth, green, ſize of a large pea, one-celled, one-ſeeded, growing black as it dries. Seed one, filling the berry, ovate, white. The wood is uſed by the cabinet-makers.—Native of Japan near Nagaſaki, &c. It flowers in june.

4. Branches round, ſmooth, aſh-coloured. Leaves ſeſſile, about eight in a whorl, blunt, entire, ſmooth; above green, convex, with a groove in the middle; beneath concave, with the margin and two lines raiſed, pale; ſpreading, a finger's length and more.—Native of Japan[n].

Loureiro's *Sebifera glutinoſa* is perhaps the ſame with *Taxus macrophylla* of Thunberg. It is certainly very nearly allied to this genus.]

PROPAGATION AND CULTURE.

Sow the berries in autumn, as ſoon as they are ripe, without clearing them from the pulp, upon a ſhady bed of freſh undunged ſoil, covering them about half an inch thick with the ſame earth. In the ſpring clear the bed carefully from weeds, and if the ſeaſon prove dry, refreſh the bed with water occaſionally, to promote the growth of the ſeeds, many of which will come up the ſame ſpring, but others will remain in the ground until autumn or ſpring following; but where the ſeeds are preſerved above ground, until ſpring before they are ſown, the plants never come up until the year after.

In this bed, conſtantly well cleared from weeds, the plants may remain two years; when they ſhould be removed, in autumn, into a ſpot of freſh undunged ſoil, divided into beds four or five feet wide. Set them in rows a foot aſunder, and ſix inches from each other, obſerving to lay a little mulch upon the ſurface of the ground about their roots, as alſo to water them in dry weather until they have taken root, after which they will require no farther care, but to keep them clear from weeds in ſummer, and to trim them according to the purpoſe for which they are deſigned.

In theſe beds they may remain two or three years, according as they have grown, when they ſhould be removed, in autumn, into a nurſery; placing them in rows at three feet diſtance, and the plants eighteen inches aſunder in the rows; and trimming them in ſummer according to the deſign for which they are intended. In three or four years they may be tranſplanted where they are to remain; always ob-

ſerving

Digitized by Google

ſerving to remove them in autumn where the ground is very dry, but on cold moiſt land it is better in the ſpring. Theſe trees are very ſlow of growth.

[Mr. Boutcher adviſes, that the ſeeds ſhould be diveſted of their pulp before they are ſowed. In this caſe ſome will appear the following ſpring; but as theſe will be much the ſmaller part, he adviſes the ſeeds to be mixed with earth till ſpring.

The Yew may likewiſe be propagated by cuttings of one or two years growth, planted in a ſhady border, the beginning of april, or the end of auguſt: torn branches are preferable for this purpoſe. In two years they will be fit for removal to another nurſery, where they may remain three years, and ſo on, according to the ſize required. No tree is more patient of being tranſplanted old than the Yew; ſo that you may at once form with it hedges ſeven or eight feet high. It ſhould be a rule never to clip theſe hedges in autumn.

DESCRIPTION, *&c.*

Trunk erect, growing to an immenſe ſize: bark aſh-coloured. Branches croſs-armed, numerous, ſpreading: young ſhoots four-ſided; ſides channelled. Leaves oppoſite, ſpreading, ovate, a little ſcolloped, above ſcabrous, beneath covered with ſoft white down; larger at a diſtance from the flowers, and on young trees from twelve to twenty-four inches long, and from eight to ſixteen broad. Petiole ſhort, thick, laterally compreſſed. Panicle terminating, very large, croſs-armed: diviſions dichotomous, with a ſeſſile fertile flower in each cleft; the whole covered with a hoary farinaceous ſubſtance. Common peduncle quadrangular, with the ſides deeply channelled, and the angles obtuſe. Bractes oppoſite, lanceolate, two at each ſubdiviſion. Flowers ſmall, white, very numerous, fragrant. Calyx and corolla oftener ſix-cleft than five-cleft. Nectary very ſmall; often wanting. Stamens oftener ſix than five. Stigma two-cleft: diviſions obtuſe and ſpreading. Nut exceeding hard, four-celled[o].

In the Supplementum Plantarum of the younger Linneus it is ſaid that the bark is like that of the Alder; the larger leaves pendulous, parabolic, acute, for the moſt part oblique at the baſe, ſilvery beneath, ſmooth above with very minute white dots; the common peduncle erect; calyx white-tomentoſe; corolla ſcarcely bigger than the calyx, pubeſcent on the outſide with black dots interſperſed; nectary red-orange; anthers tawny; germ white-villoſe; drupe ſize of a hazel nut.

Loureiro deſcribes the bark as ſmooth, and the branches aſcending; leaves very large, ovate, acute, quite entire, oblique at the baſe, with ribs oppoſite, curved in, thick; flowers white, terminating, in large, upright racemes, regularly divided; corolla five-parted; drupe ſmall, roundiſh, three-celled, covered with the inflated calyx, which is five-cleft and gaping at the top.

According to Gærtner, the drupe is hirſute all over with roughiſh curled aſh-coloured villoſe hairs; the rind friable; the ſhell bony, marked with four raiſed narrower ribs, and as many thicker rounded ſwellings, and perforated at the axis. Seed one in each of the four cells, lens-ſhaped ſwelling a little, having an umbilical chord from the top to the bottom, faſtened to the vertex of the cells.

Native of the vaſt foreſts in Java and Ceylon, Malabar, Coromandel, Pegu, Ava, the confines of Cochinchina and Cambodia, &c. On the coaſt of Coromandel it flowers in the hot ſeaſon; and the ſeed is ripe in auguſt and ſeptember. Lord Cornwallis and Colonel Kyd begun ſome time ago to introduce it into Bengal, where it thrives well.

The wood of this tree has by long experience been found to be the moſt uſeful timber in Aſia: it is light, eaſily worked, and at the ſame time both ſtrong and durable: that which grows near the banks of the Godavery is beautifully veined, and very cloſely grained; it is particularly fit for furniture, gun-carriages, &c. where ſmall timber is wanted. For ſhip-building the Teak is reckoned ſuperior to any other ſort of wood, being light, ſtrong, and very durable, either in or out of the water. Pegu produces the largeſt quantity, the large rivers there enable the natives to bring it down to the ſea ports from the interior mountainous parts of the country where it grows, at a cheap rate, which enables them to ſell it lower than in any other part of India[p].

The trade between Calcutta, Madras and Rangoon (the principal port of Pegu) has of late years rapidly increaſed, particularly on account of Teak timber, the produce of Ava and Pegu, whence Calcutta and Madras draw all their ſupplies of wood for ſhip-building, and various other purpoſes: it being conveyed from the Malabar to the Coromandel coaſt, or to Calcutta, at an expenſe ſo great as to preclude the attempt. The commerce in this article is ſo extenſive, as to require an annual return of Indian commodities to the amount of £.200,000 ſterling. And it is produced in the foreſts of the Birman and Pegu empires in inexhauſtible abundance.

A durable veſſel of burthen cannot be built in the river of Bengal, without the aid of Teak plank. Within the laſt ſix years (previous to 1795) ſome of the fineſt merchant ſhips ever ſeen in the river Thames, have arrived from Calcutta, where they were built of Teak timber. Madras alſo is ſupplied from Rangoon, with timber for all the common purpoſes of domeſtic uſe; and even Bombay, although the coaſt

of Malabar is its principal ſtore-houſe, finds it worth while, annually to import a large quantity of planks from Pegu[q].

This tree was introduced at Kew in 1777, by John Walſh, Eſq.[r]

DESCRIPTIONS, *&c.*

1. Root compoſed of yelloviſh woody fibres, ſpreading out wide. Stalks and branches ſlender, trailing, eight or nine inches long. Leaves ſmall, ovate, grayiſh, ſmooth and pretty ſtiff, having one longitudinal nerve running through the middle. Flowers terminating, in ſhort thick bunches, reflexed like thoſe of Heliotrope.

[Stem proſtrate, ſmooth, round, ſcarcely branched. Leaves glaucous, elliptic, quite entire, narrower at the baſe, thick, hard, ſolid. Flowers in a cloſe corymb, white. Styles three, converging at the baſe[t]. Capſule ovate, contracted at top into a point, three-ſided, having a depreſſed ſtreak along the middle of each ſide. Seeds about twelve, ovate-globular, ſomewhat kidney-ſhaped, ſcarcely or very ſlightly compreſſed, dotted all over with very minute raiſed dots, but ſmooth and of a very dark colour not ſhining; faſtened to a ſhort, free central receptacle[u].

Native of the South of France, Spain, Switzerland, Italy and Barbary.—It flowers from june to auguſt; and was cultivated by Mr. Miller in 1739[w].

2. Native of Barbary, where it was found by Shaw; and is diſtinguiſhed by its larger conjugate leaves.]

DESCRIPTIONS, &c.

1. This is a large tall leafy tree, with ſpreading branches in whorls. Leaves at the ends of the branches in cluſters, ſpreading, obovate or ſubcordate, marked with a notch, ſomewhat tomentoſe beneath, on ſhort roundiſh petioles. Racemes among the leaves, very many, round. Bractes oblong, caducous, cordate. Racemelets cylindrical. Hermaphrodite flowers few, more remote, at the baſe of the racemelet, ſmaller than thoſe of the Currant[r]. The fruit is a drupe, three inches long, egg-ſhaped, grooved, containing an oblong kernel, that has the taſte of an Almond, and may be uſed for the ſame purpoſes, but it has not ſo much oil. At Banda and Batavia it appears in the deſert, and is much liked by Europeans. Rheede ſays that the Catappa bears ripe fruit three times in a year. This tree is commonly planted near houſes, in wide areas, and ſeats are placed under it, for the enjoyment of the cloſe extenſive ſhade which it affords. The timber is fit for ſhip-building, being light and laſting many years in ſalt water. The bark and leaves yield a black pigment, with which the Indians dye their teeth, and Indian ink is made[s].

Native of the Eaſt Indies. Introduced in 1778, by Meſſ[rs]. Kennedy and Lee[t].

2. This alſo is a lofty widely-branching tree, with a ſtraight ſtem clear of branches to a great height; the branches moſtly oppoſite, round, ſpreading, ſmoothiſh, with a cinereous cloven bark. Leaves terminating in cluſters, ovate and obovate, bluntiſh, quite entire, ſpreading, ſmooth, even, a ſpan long, on round ſpreading petioles, covered with a browniſh pile, and ſcarcely an inch in length. Peduncles from the axils of the upper leaves, ſimple, round, filiform, erect, bent down at the top, ſmooth, a ſpan long. Raceme quite ſimple, with the flowers ſcattered and whitiſh: the males on the upper part, pedicelled; the hermaphrodites below, numerous, up to the middle of the raceme, very like the others, but really ſeſſile; the germ itſelf being inferior, and performing the office of a pedicel.

It differs from the preceding, in having the leaves only half the ſize, and without any pubeſcence on the lower ſurface; the nut only one third of the ſize, oval, not at all grooved or margined, but as it were appendicled with an acute, compreſſed, membranaceous apex.

Native of the Society and Friendly iſles in the South Seas. In the former it is cultivated near their huts and in their burial places. In the language of Otaheite it is named *Auwiri*, or *e-Tara-iri* and *e-Tara-beiriri*, and is accounted ſacred to their idols. The wood is uſed in building boats, and making drums, benches, &c. The kernels are eaten, and have the flavour of almonds[b].

3. This tree has a very large trunk, and grows to a vaſt height, covered with a gray or very light-brown bark, ſeeming to be looſe and come off in long pieces; it has here and there ſome knobs or eminencies on its ſurface, the leaves are very large and long. It grows in all the inland great woods of the iſland of Jamaica[c].

4. This alſo is a native of Jamaica[d].

5. This tree ſcarcely exceeds three or four times the height of a man, and is not much diffuſed. Branches ſcattered, covered with an aſh-coloured bark. Leaves moſtly oppoſite, quite entire; the younger ones ſilky-hirſute. Under the leaf on the upper ſide of the petioles are two glands, and ſometimes two others in the very baſe of the leaf, eſpecially in the tender leaves. Peduncles racemed, with the flowers ſeſſile in whorls, at the ends of the branchlets. Calyx bell-ſhaped, ſhort, five-toothed, outwardly naked, yelloviſh, inwardly bearded. Glands at the bottom oblong, denſely bearded. Filaments twice as long as the calyx. All the flowers are hermaphrodite, but thoſe which are fertile may eaſily be diſtinguiſhed from the barren ones, by having the germ thickened at the baſe.—Native of the Eaſt Indies, where it was found by Koenig[e].

6. Bark ſmooth, or very minutely cloven, brown. Branches in whorls, leafy at the end, ſpreading, ſimple, hairy. Leaves in cluſters, petioled, repand, hairy, green with blood-red netted veins. Stipules none. Raceme horizontal, immediately below the leaves, ſimple, ſhort, male flowers with one hermaphrodite. Germ inferior obclavate or ovate-oblong, contracted at the neck. Drupe boat-ſhaped or concave, convex on the other ſide. Nut bony, very hard, ovate, obtuſe, ſharp. The bark on the wood of the officinal Benzoin which Thunberg brought over reſembles that of this tree very much[f]. But that is now aſcertained to be a ſpecies of Styrax.

Native of the Eaſt Indies. Cultivated in 1757, by Mr. Miller[g].

Terminalis. See *Dracæna*.]
Ternatea. See *Clitoria*.

GENERIC

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-parted, upon which two ſmaller *ſcales* are incumbent: all the *ſegments* are orbicular, concave, and permanent.

COR. one-petalled, bell-ſhaped: *tube* none: *border* five-parted: *ſegments* orbicular, concave, emarginate, longer than the calyx.

STAM. *Filaments* numerous, filiform, inſerted in a double row into the baſe of the corolla, and ſhorter than it. *Anthers* linear, erect, length of the filaments.

PIST. *Germ* ſuperior, roundiſh. *Style* cylindric, length of the ſtamens. *Stigma* capitate.

PER. *Berry* juiceleſs, ovate, even, two-celled.

SEEDS about eight, convex on one ſide, flat on the other.

ESSENTIAL CHARACTER.

Cal. five-parted. *Cor.* one-petalled, wheel-ſhaped, with the border bell-ſhaped, five or ſix-parted. *Anthers* thick at the tip. *Berry* juiceleſs, two-celled.

SPECIES.

1. Ternſtroemia meridionalis.
   Lin. ſyſt. 487. *ſpec. ed. Willd.* 2. 1128. *ſuppl.* 264. *Vahl ſymb.* 2. 60. *Swartz prodr.* 81. *obſ.* 207. *Mutis amer. t.* 9.
   Leaves obovate emarginate quite entire, peduncles axillary.
2. Ternſtroemia elliptica.
   Lin. ſpec. ed. Willd. 2. 1128. *Vahl ſymb.* 2. 61. *Swartz prodr.* 81.
   Leaves elliptic quite entire, peduncles lateral.

   Cleyera japonica. *Thunb. jap.* 224.
   Leaves ovate-lanceolate ſerrulate at the tip, peduncles lateral.
5. Ternſtroemia dentata.
   Lin. ſpec. ed. Willd. 2. 1129. *Swartz prodr.* 81.
   Taonabo dentata. *Aubl. guian* 1. 569. *t.* 227.
   Leaves oblong acuminate tooth-ſerrate, peduncles axillary and lateral.

DESCRIPTIONS, *&c.*

1. This is a tree with determinate branches, and more ſimple ſtiffiſh branchlets, with an aſh-coloured bark. Leaves alternate, ſubpetioled, coriaceous, perennial, oval, obtuſe, ſubemarginate, ſomewhat recurved at the edge, quite entire, veinleſs. Stipules none. Peduncles thick, compreſſed-ancipital, ſhorter by half than the leaves, drooping. Calyx rigid, almoſt cartilaginous. Corolla moſtly five-parted, ſeldom ſix-parted, white; firſt globular, then bell-ſhaped. Berry dry, falling when ripe without ſplitting. Seeds blood-red, ſilky[h].

Swartz remarks, that the flowers are whitiſh below, but yellow above; and the ſeeds ſcarlet.

According to Vahl it differs little from the next ſpecies: the leaves are ſhorter, acute at the baſe, rounded at the top and emarginate; and the peduncles are commonly longer than the leaves.

Found in New Granada by Mutis; and ſince in Jamaica, Nevis and Dominica by Swartz.

2. The branches have a ſmooth wrinkled bark. Leaves at the top of the branches, ſcattered, alternate, two inches long and more, quite ſmooth, coriaceous, a little bent back at the edge, having numerous minute raiſed dots ſcattered over both ſurfaces, narrower at the baſe, above veinleſs, ſhining. Petiole ſhort, flat above, convex beneath. Peduncles towards the top, a little above the leaves, ſcattered, an inch long, one-flowered, purpliſh. Calyx-leaves blunt, coriaceous[i].

Willdenow remarks, that the leaves are rather obtuſe than acute.

[h] Linn. ſuppl. [i] Vahl.

Native of the Weſt Indies, Guadeloupe, St. Vincent's, &c.

3. This is a tree of about twenty-five feet in height, and branching in a ſcattered manner at the top: the leaves are alternate, ovate, of an obſcure green, ſmooth, and marked with rough dots on the edges: the flowers are yellowiſh and ſtand on longiſh foot-ſtalks.

Native of Guiana, in the woods of Serpent mountain[k].

4. Stem arboreous, branched, ſmooth all over. Branches and branchlets ſubverticillate, three, four or five together, cinereous, wrinkled, directed one way, upright. Leaves at the very ends of the final branchlets, in a ſort of whorl, four, five or ſix together, unequal, oblong-ovate, obtuſe, thick, evergreen, bright green above, paler beneath, flat, an inch and half long. Petioles half round, grooved above, red, a line in length. Flowers axillary, one, two, or three together, on drooping, one-flowered peduncles, half an inch long.—Native of Japan; flowering in the autumnal months[l].

5. A tree, of the height of about twenty feet, ſpreading into ſeveral ſtraight but bending branches at the top: theſe branches divide into alternate, leafy branchlets: the leaves are ovate, alternate, ſmooth, ſerrated, and terminate in a long point: the flowers ſpring ſingly from the branchlets and the boſoms of the leaves, and are of a yelloviſh colour[m].

Native of the woods of Guiana, flowering in auguſt and ſeptember.

Leaves oblong acute almoſt quite entire ſomewhat rugged beneath, panicle terminating.

DESCRIPTIONS, *&c.*

1. Calyx-leaves often ſix. Capſule ovate, attenuated, ſmooth, opening longitudinally on one ſide. Seed one, ſmall, black, girt below by a toothletted aril[n].—Native of the Eaſt Indies. See DELIMA.

2. A ſhrub, with long downy twigs, and alternate, ſharp-pointed, toothed leaves, which are of a bright green above, and downy beneath: the flowers are white. It is a native of Guiana, flowering in january.

3. A ſhrub, with ſeveral rough ſtems or twigs, ſubdividing into long branches and branchlets, which riſe to the branches of the neighbouring trees, and, bending over them, hang downwards to the ground: the branches, branchlets, and even the leaves are very rough: the latter ſtand alternate, and are roundiſh and ſlightly undulated on the edges: the flowers, according to Aublet, are male and female, and are of a white colour.

Native of Guiana, where it grows in woods, ſometimes ſo very plentifully as to be extremely inconvenient to thoſe who endeavour to walk in them[o].

4. A ſhrub, with a climbing ſtem, and alternate, ovate, toothed, pointed leaves: the flowers are rather ſmall, and are ſucceeded by rounded or globoſe capſules.—Native of Surinam.

5. A ſhrub, riſing with a ſtraight ſtem: leaves ovate, lanceolate, and toothed: flowers borne at the extremities of the branches.—Native of Surinam[p].

6. See *Doliocarpus Calinea.*

7. See *Mappia guianenſis.*

8. Branches round, ſmooth. Branchlets moſtly two-parted, ſomewhat hairy, rugged. Leaves alternate, three or four inches long, ſomewhat ſhining, marked with lines above along the nerves, beneath in a manner ribbed with the raiſed nerves; the nerves beneath and the rib on both ſides villoſe; they are veined, rugged eſpecially the younger ones, bluntiſh; ſometimes obſcure remote toothlets run from the nerves a little beyond the edge: the younger leaves when examined with a magnifier appear to have minute whitiſh ſcales ſcattered over the upper ſurface; the older ones are marked with impreſſed dots. Petiole ſhort, convex beneath, channelled above from a thin upright margin. Racemes a little above the axils of the upper leaves, and from the end of the branchlets, compound, longer than the leaf. Partial peduncles and pedicels alternate, filiform, villoſe, purpliſh. Bracte ovate, membranaceous, acute, at the baſe of the partial peduncles. Calyx five-leaved: leaflets roundiſh, the three outer ſmaller, ſhort, the two inner larger, concave, ſmooth, the edges appearing to be ſubciliate when examined with a magnifier. Corolla four-petalled: petals roundiſh, a little plaited and waved about the edge, two ſomewhat leſs than the others. Filaments length of the petals, ſmooth. Anther on each ſide by the ſide of the filament towards the top. Germ ovate, acute, ſmooth. Style length of the filaments. Stigma flat, ſubpeltate. Suppoſed to have been found in the iſland of Trinidad by von Rohr.

9. Leaves petioled, paler underneath, two inches long and more[q]. See EURYANDRA.]

10. This has a woody ſtalk riſing to the height of twelve or fourteen feet, covered with a gray bark, and ſending out ſeveral ſlender woody branches which twine about any neighbouring ſupport. Leaves oblong-ovate, near ſix inches long, and two inches and a half broad, ſlightly indented on their edges towards their points, and having many tranſverſe veins running from the midrib to the edges; they are placed alternate on the branches, ſtand upon ſhort foot-ſtalks, are of a grayiſh colour on their upper ſurface, and brown on their under. The flowers are produced in panicles at the end of the branches; theſe panicles are compoſed of three or four ſhort thick ſpikes, which branch out from the lower part of the principal ſpike, which is much longer and thicker than the others. The flowers have ſix thin purple petals, of the ſame length as the calyx, and very fugacious. The four germs become ſo many oval capſules, which are reflexed, open lengthwiſe on the upper ſide, and have each one oblong ſeed incloſed. Mr. Miller affirms, that this ſhrub is very different from the *Fagus americana,* &c. of Plukenet: [but that is continued as a ſynonym by Gærtner, Willdenow, &c.

Capſules acuminate both ways, ſpreading horizontally, coriaceous, ſmooth, very dark cheſtnut-coloured, one-celled. Seed ovate, ſomewhat wrinkled and angular, black, ſhining, very minutely dotted; ſurrounded by a fleſhy membranaceous aril, which is white, quite entire below, faſtened to the navel, above divided longitudinally by a cleft, and thence towards each ſide deeply cloven into linear parallel ſegments: the ſeed is faſtened to the bottom of the capſule[*].

Native of South America.] Mr. Miller ſays, it grows naturally at La Vera Cruz, where it was diſcovered by Dr. Houſtoun, who ſent it to England. He received it alſo from the iſland of Bermuda, where it was found by Dr. Creſſy.

11. Branchlets flexuoſe, with an aſh-coloured bark, ſmooth, ſomewhat angular. Leaves alternate, attenu-

[n] Vahl. [o] Aublet. [p] Roland. [q] Vahl. [*] Gærtner.

Digitized by Google

ated at the baſe, obſcurely ſerrate at top with a few teeth, two or three inches long, veined, ſmooth on both ſides, on very ſhort petioles. Peduncles ſolitary or two together, an inch long. Flowers in a ſort of raceme, on one or two-flowered pedicels. Calyx-leaves ſix, roundiſh. Styles two, awl-ſhaped. Capſules four, roundiſh, ventricoſe, mucronate, very ſmooth, ſhining. Seed one, ſmall, black, ſhining, covered below up to the middle with a whitiſh aril toothletted at the edge.—Native of the Eaſt Indies[t].

12. Branches round, ſmooth. Leaves alternate, petioled, coriaceous, attenuated at the baſe, rounded at the tip, moſtly quite entire at the edge, but ſometimes having an obſcure tooth or two at the tip, parallel-netted veined, ſmooth and ſhining above. Calyx four-leaved. Corolla ſeems to be five-petalled. Filaments widening a little at the top. Anther on each ſide. Capſules four, one-ſeeded. Seed black, wholly covered with a whitiſh aril. Panicle ſimple. Peduncles three-flowered.—Native of Guinea[u].

We have here many diſtinct genera of various authors united under one, from their agreement in the general characters. As *Delima* of Linneus, *Rhinium* and *Mappia* of Schreber, *Tigarea*, *Calinea* and *Soramia* of Aublet, *Doliocarpus* of Rolander, and *Faryandra* of Forſter. Willdenow ſuſpects, that *Aſſa indica* of Houttuyn, (*ſyſt.* 4. *p.* 40. *t.* 26.) is a ſpecies of this genus.]

PROPAGATION AND CULTURE.

The ſeeds being procured from the countries where the plant naturally grows ſhould be ſown in pots filled with light earth, and plunged into a moderate hot-bed of tanners bark, where they muſt be treated in the ſame way as other exotic ſeeds from the ſame countries: and as the plants ſeldom come up the ſame year, the pots ſhould be removed into the ſtove before winter, and plunged into the tan-bed between the other pots of plants, where they ſhould remain till ſpring, when they ſhould be taken out and plunged into a freſh hot-bed of tanners bark, which will bring up the plants if the ſeeds were good. When the plants are fit to remove, they ſhould be each planted in a ſeparate ſmall pot filled with light earth, and plunged into a good bed of tan, ſhading them from the ſun till they have taken new root; after which their treatment muſt be the ſame as for the Annona, and the like tender exotic plants, which require to be kept always in the tan-bed.

TETRAGONIA. (*Abbreviated by Linneus, from* Tetragonocarpus *a name of Commelin's, given from the four-cornered form of the fruit.*)

Lin. gen. n. 627. *Reich. n.* 683. *Schreb. n.* 859. *Gærtn. t.* 127. 179. *Juſſ.* 317.

Claſſ. 12. 4. Icoſandria Pentagynia.

Nat. order of *Succulentæ*. *Ficoideæ* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* four-leaved, ſuperior: *leaflets* four, ovate, bent down and flat, rolled back at the edge, coloured, permanent.

COR. none, unleſs the calyx be called ſo.

STAM. *Filaments* twenty, capillary, ſhorter than the calyx. *Anthers* oblong, incumbent.

PIST. *Germ* roundiſh, five-cornered, inferior. *Styles* four, awl-ſhaped, recurved, length of the ſtamens. *Stigma* longitudinal of the ſtyle, pubeſcent.

PER. *Drupe* coriaceous, four-cornered with four longitudinal wings, the oppoſite angles narrower, not opening.

SEED one, bony, four-celled: *kernels* oblong.

OBS. *The firſt flower adds a fifth part of the number in every part of the fructification: hence, according to the general rule, it is placed in the order pentagynia.*

ESSENTIAL CHARACTER.

Cal. three to five-parted. *Pet.* none. *Drupe* inferior, incloſing a nut from three to eight-celled.

Herbaceous froſty, leaves ovate ſeſſile, fruits unarmed.]

DESCRIPTIONS, &c.

1. Stems ſlender woody, riſing three or four feet high if ſupported, otherwiſe trailing, covered with a light gray bark, and dividing into a great number of trailing branches, which when young are ſucculent, of an herbaceous colour, and covered with ſmall pellucid drops, which reflect the light, ſomewhat like the Diamond Ficoides. As the branches grow older, they become more woody. Leaves narrow, thick, ſucculent, about half an inch long, and a tenth of an inch broad, concave and blunt-pointed; they are placed alternately, and at their baſe comes out a cluſter of ſmaller leaves, which have the like pellucid drops with the ſtalks. Flowers axillary, at every joint towards the ends of the branches, ſolitary, or two or three together. Calyx-leaves five, ſpreading and a little reflexed, green without and yellow within. Stamens about forty, terminated by oblong proſtrate anthers which fill up the middle of the flower. [In the axils of the leaves are numerous ſmaller leaves, or rudiments of branches. The flowers are ſolitary or digeſted into a terminating raceme[v].

The fruit is an inferior juiceleſs drupe, with eight wings, alternately larger and ſmaller, but all rounded, leafy-compreſſed and coriaceous: ſhell in the upper part of the drupe, bony, ovate-globular, having alſo eight rounded wings alternately larger and ſmaller, four-celled, valveleſs; cells very ſmooth within, cheſtnut-brown. Seeds ſolitary, attenuated upwards and elongated from a ſubglobular baſe, ſmooth, cheſtnut-ruſt-coloured, faſtened by a ſhort umbilical chord to the top of the cells. Embryo inverted, curved and hooked[w].

This and all the ſpecies except the two laſt are natives of the Cape of Good Hope.—It was cultivated in 1712, by Biſhop Compton; and flowers from july to ſeptember[x].]

2. This has larger ſtalks than the preceding, but they branch out in like manner; the branches trail upon the ground; the young branches are very ſuccu-

[t] Vahl. [u] Willdenow. [v] Linn. mant. [w] Gærtner. [x] Hort. kew.

lent,

Digitized by Google

lent, and almoſt as thick as a man's little finger. The leaves are two inches long, and an inch broad; their ſurface covered with very ſmall pellucid drops, as are alſo the young branches. Flowers larger, upon pretty long foot-ſtalks, three or four from the ſame point. Calyx and anthers of a pale ſulphur colour.

[Cultivated by Mr. Miller in 1758. It flowers from july to ſeptember[y].]

3. This has large fleſhy roots. Branches weak and trailing, generally decaying about midſummer, and new ſhoots produced late in autumn. The leaves come out in bunches; they are oval, plane, and not ſo thick and ſucculent as in the other ſorts; they are little more than an inch long, and half an inch broad. The flowers are produced from the wings of the leaves in february: they are like thoſe of the ſecond ſort, and have long ſlender foot-ſtalks.

[Axils moſt commonly without any rudiments of branches. Peduncles three, one-flowered from the axils of the leaves; which are obovate-lanceolate[z].

Cultivated in 1759, by Mr. Miller. It flowers in june and july[a].

4. 5. Theſe were found at the Cape by Thunberg.

6. Root biennial. Stem herbaceous, near the root dividing into diffuſed branches, rendered angular by the petioles running down them, ſcarcely a foot long. Leaves ſucculent, ſpreading, an inch in length: petioles ſhorter by half than the leaves. Peduncles axillary, ſolitary, filiform, covered with ſhining bladders, purple, very ſhort. Flowers pendulous, appearing as if froſted with cryſtalline bladders. Calyx three-leaved or four-leaved, yellowiſh green within. Stamens commonly three, ſeldom four. Germ flat beneath, three-ſided; the angles echinate with many conical proceſſes. Styles three. Nut three-celled. Found at the Cape by Maſſon, and introduced in 1774. It flowers from may to auguſt[b].

7. Stem herbaceous, even, procumbent, branched, ſomewhat angular with raiſed ſtreaks from the decurrent margins of the petioles, a little thicker than a gooſe quill, weak. Branches numerous, elongated, round, ſpreading. Leaves alternate, bluntiſh, quite entire, horizontal, ſhorter than the internodes, an inch and half long. Petioles ſlender, flattiſh above, an inch long. Peduncles ſubſolitary, axillary, one-flowered, very ſhort. Flowers yellow. Calyx four-parted, ſeldom five-parted, coloured within, one wider and more rounded than the reſt. Stamens ſixteen or twelve. Germ very ſmall. Styles ſix, ſeldom five. Drupe rude, turbinate or obconical, fleſhy, four-cornered or five-cornered towards the top, horned with the acute angles being more produced. Nut bony, with cells correſponding to the number of ſtyles; containing one ovate white kernel. The whole plant is ſtudded with very minute cryſtalline dots, as in ſome ſpecies of Atriplex, Chenopodium and Meſembryanthemum[c].

According to Scopoli, the ſtem is a foot high, upright, with ſpreading branches from the very bottom, moſtly ſimple, covered with ſmall confluent tubercles. Leaves thickiſh, tubercled; the tubercles on the back more ſhining; waved or ſubſinuate. Petioles channelled, ſpreading. Flowers ſolitary from the axils, ſeſſile or ſhortly peduncled. Calyx four-toothed, with ſhining granules ſcattered over it, and from the baſe of each tooth a petal-ſhaped lamiella, of a ſubovate form, granulated, and of a yellowiſh-green colour. Stamens to ſixteen, four from each angle, alternate with the teeth of the calyx. Styles five. Fruit four-cornered, four-horned, four-celled, with one ſeed in each cell; ſometimes five-celled, and even eight-celled. Seeds oblong, ſlightly gibbous, ſmooth, yellow on the outſide, white within.

Thunberg, who at firſt took the Japoneſe plant to be a ſpecies diſtinct from this, deſcribes it as wholly ſucculent and ſmooth: the ſtem angular, decumbent, ſimple, a foot high. Leaves ſubcordate, ovate, ſomewhat angular, acute, entire, dotted all over with very ſmall pores, two inches long, the upper ones gradually ſmaller, on ſhort petioles widening by degrees into the leaf. Flowers axillary, ſolitary, on peduncles half a line in lengh. Calyx four-parted. Drupe four-cornered, four-horned, the ſize of a pea.

Gærtner deſcribes the fruit as a juiceleſs inferior drupe, ſubturbinate, rhomb-compreſſed, obſcurely grooved, crowned with the converging four-toothed calyx, four-horned: rind herbaceous-membranaceous, ending above in the calyx, below in the peduncle, but within between the baſe of the ſhell and the origin of the peduncle having an almoſt hemiſpherical cavity either quite empty, or with a cellular-cobwebby ſubſtance in it. Shell ſomewhat bony, ſhorter by half than the fruit; the naked ferruginous ſix or eight-tubercled top prominent within the cavity of the calyx, the reſt covered with the rind, four-horned, eight-grooved, ſix or eight-celled. Seeds ſolitary, hooked and doubled together, narrowing upwards, red-ferruginous. Embryo inverted, yellowiſh, curved and hooked.

Native of New Zealand, by the ſides of woods in buſhy ſandy places; alſo within the tropics on the ſhore of the iſland Tongatabu: and in Japan. Though not uſed by the inhabitants, it is a very good pot-herb. By the orders of Captain Cook, whilſt they were in port it was ſerved to the ſailors boiled every day at breakfaſt and dinner[d].

It is a biennial plant, and was introduced in 1772, by Sir Joſeph Banks. It flowers here in auguſt and ſeptember[e].

8. Root annual. Plant a ſpan high, the whole covered with cryſtalline papillæ. Stem in a manner upright, round, the thickneſs of a reed. The bottom branches only oppoſite, all the reſt alternate, dichotomous at the top, ſpreading a little. Leaves alternate, except the two lower which are oppoſite, acute, quite entire, three-nerved, ſomewhat fleſhy, ſoft, bright green on both ſides, ſpreading, gradually ſmaller upwards, from eighteen to thirty lines in length, and from ten to fifteen lines in breadth. Flowers ſolitary, or very ſeldom two together, the uppermoſt remote from the axil; the reſt axillary, ſubſeſſile, erect, tawny. Peduncles round, growing in length when bearing fruit. Calyx four-parted, as it were four-leaved. Stamens about ſixteen, inſerted into the baſe of the calyx: anthers roundiſh, two-celled, ſubpeltate. Germ turbinate-quadrangular, as it were the baſe of the calyx running down, and of the ſame ſubſtance, in the centre of which the germ properly ſo called is almoſt immerſed, ovate and pubeſcent. Styles four, diverging, upright, pubeſcent. Drupe dry, ſpongy, obovate-turbinate, quadrangular, umbilicate, one-celled, cinereous, brown within, pubeſcent, four lines long and three wide. Seed a four-lobed nut, ſometimes as it were beaked at the top, four-celled.

Found in Chancaye a province of Peru by Dombey, whence he ſent the ſeeds to the Paris garden, where it flowers and fruits during the ſummer, growing up and periſhing in a few months[f]. It was introduced at Kew in 1788, by Monſ. Thouin[g].]

PROPAGATION AND CULTURE.

1—6. Theſe may be propagated by cuttings, which ſhould be cut off from the plants a few days before they are planted, that the part where they are cut may be healed, otherwiſe they will rot, for the leaves and ſtalks are very full of moiſture. The beſt time to plant theſe cuttings is in july, that they may have time to make good roots before winter. Theſe cuttings may be planted on a bed of freſh earth, and if they are ſhaded from the ſun in the heat of the day, it will be of ſervice to them. They ſhould be frequently refreſhed with water, but they muſt not have it in too great plenty, for that will rot them. In about ſix weeks after planting, the cuttings will be ſufficiently rooted to tranſplant, therefore they ſhould be taken up, and planted into pots filled with

[y] Hort. kew. [z] Linn. mant. [a] Hort. kew. [b] Idem. [c] Forſter, eſcul. [d] Forſter, eſcul. [e] Hort. kew. [f] L'Heritier. [g] Hort. kew.

Digitized by Google

light freſh undunged earth, and placed in a ſhady ſituation until they have taken new root, after which time they may be placed with other hardy exotic plants in a ſheltered ſituation, where they may remain till the middle or latter end of october; at which time they ſhould be removed into the green-houſe, and placed where they may enjoy as much free air as poſſible in mild weather; for they only require to be protected from the froſt, being pretty hardy with reſpect to cold, but they ſhould not have too much moiſture in winter. If theſe plants are planted in the full ground in the ſummer ſeaſon, they will grow prodigiouſly rank and large; as they alſo will, if they are permitted to root into the ground through the holes at the bottom of the pots; therefore the pots ſhould be frequently removed to prevent it, for when they grow too freely, their leaves will be very full of moiſture; which, together with the weight of the fruit, which is always produced at the extremity of the branches, will weigh the branches upon the ground, and render the plants very unſightly. The plants of this kind commonly grow very ſtraggling; therefore the more their roots are confined in the pots, the more cloſe and ſtinted will be the heads of the plants; which is what they ſhould always be kept to, in order to render them ſightly. The flowers of theſe plants have no great beauty, but as their whole appearance is ſingular, they may be allowed a place in collections of plants; eſpecially as they require no great trouble in the cultivation.

The firſt and ſecond ſorts may alſo be propagated by ſeeds, ſown in a gentle hot-bed or in a warm border of light freſh earth, where ſometimes they will remain a whole year before the plants come up. When they are about four inches high, take them up and plant them in pots; treating them in the ſame manner as has been directed for the cuttings.

The third ſort never produces ſeeds in England, but will grow from cuttings planted early in the ſpring, with the ſame facility as the others.

[The two laſt ſpecies are more tender, eſpecially the eighth, and muſt be kept in the tan-ſtove. They are propagated only by ſeeds.

Tétragonia ivæfolia. See *Haloragis.*

TETRAGONOCARPOS. See *Tetragonia.*

TETRAGONOLOBUS. See *Lotus.*

TETRAGONOTHECA. See *Polymnia.*

TETRAHIT. See *Galeopſis.*

TETRALIX. See *Erica.*

TETRANTHUS. (*So named from having four flowers within one common calyx.*)

Lin. gen. Schreb. n. 1354. *Swartz prodr.* 115.

Claſſ. 19. 5. Syngeneſia Polygamia Segregata.

Nat. order of *Capitatæ.* Cinarocephalæ Juſſ.

GENERIC CHARACTER.

CAL. *Common* five-leaved, four-flowered: *leaflets* linear, erect, ciliate, at the baſe of the florets.

Perianth proper one-leafed, tubulous, attenuated at the baſe, compreſſed, oblique at the throat, ciliate at the edge, one-flowered, many times longer than the common calyx.

COR. *Compound,* uniform, equal. *Corollets* four, hermaphrodite.

Proper one-petalled, funnel-form; *tube* gradually widening; border five-cleft, unequal; the two upper ſegments ſmaller and leſs divided, the three lower more ſpreading, oblong, obtuſe.

STAM. *Filaments* five, from the baſe of the corollet, half the length of the tube. *Anther* tubulous.

PIST. *Germ* from the bottom of the perianth, under the filaments, oblong. *Style* longer than the ſtamens and corolla, filiform, divided beyond the middle. *Stigmas* reflexed, linear, obtuſe.

PER. none. *Perianth proper* unchanged, permanent, including.

SEED oblong, ſtriated, crowned with the membranaceous ciliate margin of the apex.

REC. very ſmall, naked.

ESSENTIAL CHARACTER.

Cal. common four-flowered. *Perianth* proper one-leafed. *Seeds* crowned.

SPECIES.

1. Tetranthus littoralis.
Swartz prodr. 116.

DESCRIPTION, *&c.*

It is an annual plant, native of Hiſpaniola.

TETRAPHIS. One of Hedwig's genera of Cryptogamia Muſci, or Moſſes. Species of Mnium according to Linneus.]

TEUCRII FACIE. See *Coldenia.*

TEUCRII SPECIES. See *Veronica.*

TEUCRIUM. (*So named from Teucer, ſon of Scamander, and father in law of Dardanus, king of Troy.*)

Lin. gen. n. 706. *Reich. n.* 764. *Schreb. n.* 960. *Tournef. t.* 93. *Juſſ.* 112. Polium *Tournef. t.* 98. Chamædrys *Tournef. t.* 97.

Claſſ. 14. 1. Didynamia Gymnoſpermia.

Nat. order of *Verticillatæ.* *Labiatæ* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, half-five-cleft, acute, almoſt equal, gibbous at the baſe on one ſide, permanent.

COR. one-petalled, ringent: *tube* cylindric, ſhort, ending in an incurvated throat: *upper lip* erect, acute, deeply two-parted beyond the baſe, the ſegments at the ſides diſtant: *lower lip* ſpreading, trifid: the lateral ſegments of the ſame form with the upper lip, almoſt erect; the middle one very large, and ſomewhat rounded.

STAM. *Filaments* four, awl-ſhaped, longer than the upper lip of the corolla and aſcending in the cleft of it, prominent. *Anthers* ſmall.

PIST. *Germ* four-parted. *Style* filiform, ſituation and ſize of the ſtamens. *Stigmas* two, ſlender.

PER. none. *Calyx* unchanged, foſtering the ſeeds at the bottom.

SEEDS four, roundiſh.

OBS. *The upper lip of the corolla, divided beyond the baſe and gaping, reſembles a corolla deſtitute of an upper lip.*

Teucrium *of Tournefort has a bell-ſhaped calyx, and the ſegment of the lower lip of the corolla concave.*

Polium *of Tourn. has the flowers collected into heads, terminating the branches.*

Chamædrys *of Tourn. has the flowers from the axils of the leaves, calyx tubular.*

Marum *of Boerhaave has the leaves of Serpyllium; and an acrid odour.*

ESSENTIAL CHARACTER.

Cor. upper lip two-parted beyond the baſe, divaricating where the ſtamens are.

Polium montanum album non ſerratum viride, longis anguſtiſque foliis, caule incano. *Barr. rar.* 354. *t.* 1081.
Heads terminating tomentoſe, leaves linear quite entire hoary, ſtem erect.

DESCRIPTIONS, *&c.*

1. This very much reſembles T. Botrys, but the plant is ſmooth. Root perennial. Flowers ſolitary, on peduncles ſhorter than the flower: calyxes bell-ſhaped, and not gibbous at the baſe: corollas pearly-white, incumbent on the leaf. The older ſtems are proſtrate and creeping. Leaves twice trifid. Seeds rugged [a].

Native of the Levant, and of Apulia, in moiſt ground.—Cultivated in 1728, by Mr. Miller. It flowers in july and auguſt [b].

2. Native of the Levant, it ſeems doubtful whether it be ſufficiently diſtinct from the preceding [c]. The flowers are in a raceme, larger, and blueiſh. But it varies with a bright red corolla.]

3. Root annual. Stems four-cornered, hairy, about a foot long. Leaves at every joint, oppoſite, hairy and cut almoſt to the midrib; and the ſegments cut into three points. The flowers come out from the axils in whorls, three together on each ſide, upon

[a] Linn. ſpec. [b] Hort. kew. [c] Linn. ſyſt.

ſhort foot-ſtalks: they appear in june and july. The ſeeds ripen in auguſt and ſeptember.

[Stem much branched and very leafy, ſtraight but often decumbent at the baſe. Leaves two, three or five-cleft, unequal, ſometimes entire, obtuſe; the lower on longer, the upper on ſhorter petioles. Whorls two, four, ſix or eight-flowered, ſometimes even nine-flowered, on ſhort peduncles. Corolla roſe-coloured or purple, the middle ſegment of the lower lip dotted with red. Calyx very gibbous [d].

This plant has a pleaſant aromatic odour. In character and qualities it lies between the Chamædrys and Chamæpitys, being leſs acrid than the latter, more aromatic and leſs bitter than the former: it may therefore be uſed ſucceſsfully in fevers, rheumatiſm, gout, and other maladies which depend upon the weakneſs of the ſtomach, and the tenacity of the humours [e].

Native of the South of Europe, and of Barbary about Algiers. Cultivated here before 1633; for Johnſon, in his edition of Gerarde's herbal, ſays that he has often ſeen it in gardens.

4. Root ſmall, branched, annual. The whole herb hairy, viſcid, aromatic and bitter. Stem much branched, four-cornered, leafy, often red. The two or three firſt leaves are entire; all the reſt are deeply three-cleft. Flowers axillary, ſolitary, oppoſite, ſubſeſſile, yellow dotted with red. The middle ſegment of the lower lip is obcordate. The upper lip, inſtead of being deeply divided and divaricated, with the ſtamens projecting between the lobes, as in the genuine Teuciums; is very ſhort and notched, as in the genus Ajuga. Hence Haller conſidered it as a Bugula, which is his name for that genus; and he has been followed by Schreber, Scopoli, Allioni, Roth, Willdenow, Smith, Withering and Relhan. Dr. Smith indeed acknowledges, that the habit of Chamæpitys is unlike that of Linneus's Ajugas; but at the ſame time remarks, that his Teucrium Iva, which belongs to the ſame genus, is the connecting link between them, by its pubeſcence and the denticulation of its leaves approaching Ajuga alpina, which is moreover a bitter aromatic plant [f]. The whole plant has a highly aromatic odour: and was much eſteemed formerly in the ſame diſorders as the preceding. It is an ingredient in the Portland powder.

Native of many parts of Europe, the Levant, Barbary and Virginia. In England it abounds in Kent and Surry, but is otherwiſe a ſcarce plant. It is found near Purfleet in Eſſex; about Rocheſter and Dartford, &c. Rochill. On the lays about the borders of Triplow-heath, Cambridgeſhire.

5. This is an annual plant native of Spain and Portugal. According to Schreber, it is confounded by Moriſon and Miller with T. multifiorum.—It was cultivated in 1768, by Mr. Miller; and flowers in june and july [g].

6. Stems often many in one tuft, decumbent at the baſe, four-cornered, ſimple. Leaves oppoſite, petioled, numerous; the lower bipinnate, the upper pinnate; pinnules diſtinct, linear-ſubulate, unequal, ſmooth or pubeſcent. Flowers in whorls, looſely racemed, ſolitary or in pairs from the axils, each on a ſhort pedicel. Lower bractes many-parted, longer than the calyx; upper three-parted; ſegments awl-ſhaped. Calyx bell-ſhaped, half-five-cleft; ſegments lanceolate, acute, equal. Corolla the ſame ſize as in T. fruticans; white and villoſe: tube cloven above; the two upper lobes ovate, erect: lower lip three-lobed; the middle lobe very large, ovate, concave [h].

Native of Spain, Portugal, the ſouth of France about Marſeilles, and Algiers in Barbary.

Teucrium delphinii folio, non ramoſum of Shaw, belongs to this ſpecies; and conſequently T. mauritanum of Linneus is to be expunged [i].]

7. Annual, with a ſingle woody root, ſending out a few fibres. Stalks about ſix inches high, cloſely ſet with very hairy narrow leaves, indented towards

[d] Pollich. Krock. Desfont. [e] Villars.
[f] Smith brit. & Engl. bot. [g] Hort. kew.
[h] Desfontaines. [i] Idem.

Digitized by Google

their points. The flowers come out from the axils, to which they ſit very cloſe; they are large, of a bright purple colour, and appear in july. Mr. Miller has another ſpecies (T. moſchatum n. 15.) which ſeems to be a variety of this. The leaves are narrower and entire, and the flowers are ſmaller.

[It is a very villoſe hoary plant. The ſtems are branched at the baſe and procumbent. Leaves in cluſters, moſtly obtuſe, gradually widening from the baſe to the end, ſome quite entire, others remotely ſerrate, and others having a tooth or two only at the tip. Flowers ſolitary. Corolla large, roſe-coloured, often abortive. The whole plant ſmells of muſk [k].

It has the ſame qualities with the Chamæpitys, but poſſeſſes a more volatile principle, and deſerves a place among the ſudorifics [l].

Native of the ſouth of Europe, and of Barbary. Vahl found it flowering at the beginning of october on the rocks about Marſeilles, and in various places of the kingdom of Tunis in april.

8. Found by Shaw in Barbary, but not different from T. pſeudo-chamæpitys, his figure being of that plant in a monſtrous or unnatural ſtate [m]. See n. 6. The leaves however are multifid in this, whereas in Chamæpitys they are ſimply trifid.]

9. This has a ſhrubby branching ſtalk, riſing ſix or eight feet high, and covered with a hoary bark. Leaves oppoſite, ovate, ſeſſile or on very ſhort petioles, near an inch long, and half an inch broad, ſmooth and of a ſhining green above, and hoary beneath. Flowers axillary from the upper part of the branches, one on each ſide at a joint, on ſhort peduncles. Calyxes ſhort and hoary. Corollas pale blue.

Native of Spain, Sicily, and Corſica, near the coaſt; [alſo in Barbary. Ray found it near Syracuſe, and in ſeveral other parts of Sicily; alſo at Capo Paſſaro. His friend Mr. Willughby found it in his way from Naples to Rome. Cluſius gathered it in Andaluſia, near Cadiz, and Gibraltar; flowering in february.—It was cultivated here in 1640, as appears from Parkinſon [n].

Dillenius figures a variety, which is a little more branched, and has ſmaller ſhorter leaves; the flowers are paler, the ſtamens ſomewhat longer, the anthers ſmaller and brown, whereas in the larger ſort they are violet.]

Mr. Miller mentions a variety with variegated leaves, which is preſerved in ſome gardens.

10. This is a ſhrubby plant, growing ſeven or eight feet high, and may be trained to a much greater height [o]. The flowers are ſomewhat ſhorter and ſmaller, though the leaves are larger; they are not blue but purpliſh, with more conſpicuous veins and ſtreaks: the anthers are of a duſky greeniſh colour [p].]

The leaves are broader of a rhomboid form, more hairy and whiter on their under ſide.

[Native of Spain. Cultivated in 1714, by the Ducheſs of Beaufort. It flowers from june to ſeptember. Schreber and Desfontaines conſider this as a variety of the fruticans, and Willdenow raiſed it from ſeeds which were ſent him for the fruticans.

11. Roots annual, long, twiſted, putting forth capillary branchlets. Stem erect, hirſute. Branches ſpreading, numerous. Leaves villoſe, decurrent into a ſhort petiole, deeply ſerrate, the lower obovate, the middle and upper lanceolate. Flowers axillary, ſolitary, ſeſſile or ſubſeſſile. Calyx round, gibbous at the baſe below, villoſe, five-toothed; teeth ſmall, ovate, acute, almoſt equal, mucronate. Corolla pale yellow, the ſize as in T. Chamædrys: the two lower ſegments linear, purple, blunt; the upper middle lobe larger, roundiſh.—Native of Barbary, near Maſcar, in clayey fields.

12. This is a hoary, tomentoſe, erect ſhrub, with very numerous filiform branches. Leaves white, paler above, nearly the ſize of T. marum, petioled, obovate or ovate-rhombed, nerved beneath. Flowers ſmall, axillary and terminating, ſubſeſſile, ſhorter than the leaf: calyx ſlender, elongated, white, five-toothed; teeth acute, almoſt equal: corolla violet-coloured. The whole plant breathes a very ſweet odour.

Native of Barbary, near Caſſa, in cleſts of rocks [q]: alſo of Spain.

13. Leaves acuminate, white beneath. Flowers in threes or ſolitary. Calyxes ſpiny [r].

Native of Candia and Egypt. Schreber excludes the ſynonym of Bauhin [s].]

14. This has a low ſhrubby ſtalk, ſending out many ſlender woody branches, in warm countries riſing three or four feet high, but in England rarely half that height. The ſtalks are very hoary, and have ſmall leaves placed oppoſite at each joint, about the ſize of thoſe of Thyme, and pointed at both ends, green above, hoary underneath, having a grateful ſcent, but ſo piercing as to cauſe ſneezing. The flowers grow in looſe whorled ſpikes at the ends of the branches; they are very downy, and of a bright red colour; appear in july and auguſt, but produce no ſeeds in England.—Native of Spain.

At the beginning of this century, many of theſe plants were growing in the Royal gardens at Kenſington, which were near three feet high, and clipped into conical forms. Cats are very fond of this plant, and where there are but few will deſtroy them.

[It appears from Parkinſon to have been cultivated here in 1640 [t].

The leaves and younger branches of Marum, when recent, on being rubbed between the fingers, emit a volatile aromatic ſmell, which readily excites ſneezing, but to the taſte they are bitteriſh accompanied with a ſenſation of heat and acrimony. Judging from the ſenſible qualities of this plant, it may be ſuppoſed to poſſeſs very active powers, and on this conſideration it is ſtrongly recommended by Wedelius, as an important remedy in many diſeaſes requiring medicines of a ſtimulant, aromatic, and deobſtruent quality: his opinion ſeems in ſome meaſure to have been ſince verified by actual experience of its efficacy. At preſent however Marum is here chiefly uſed as an errhine, and is an ingredient in *Pulvis aſari compoſitus*. The doſe of the powdered leaves is from a ſcruple to half a dram, which Murray adviſes to be given in wine [u].

15. The deſcription of T. niſſolianum in Miller's Dictionary, n. 8. ſeems to agree better with this ſpecies:] It is a perennial plant, having ſome reſemblance of the Chamædrys, but the roots do not creep. The ſtalks are taller and more erect, the leaves are narrower, pointed at both ends, and not ſo deeply indented; the indentures are ſharper, and only towards the point; the flowers come out in bunches from the axils, along the greater part of the ſtalk; they are longer than thoſe of Chamædrys, and of a brighter red colour.—Native of Spain. [It was cultivated by Mr. Miller in 1731 [x].

16. Stem half a foot high, villoſe. Leaves three-nerved. Flowers ſolitary, lateral, directed one way. Found in Siberia by Laxmann [y]. It is a native alſo of Hungary and Sclavonia.

17. Leaves naked on both ſides, ovate, ſerrate. Bractes under the forking two, lanceolate, mucronate, quite entire, length of the calyx, as in Satureia montana.—Native of Siberia. Perennial [z].

18. Stems diffuſed, roundiſh, pubeſcent, perennial at the baſe. Leaves oppoſite, naked, not ſhining, erect, nerved, longer than the internodes. Flowers oppoſite, on very ſhort peduncles. Calyxes tubular, half-four-cleft, narrow. Corollas three times ſhorter than the leaves, without any rudiment of an upper lip, or lateral teeth at the baſe.—Native of the Levant [a].

19. Stem erect, ſtraight, a foot high, four-cornered, browniſh, brachiate, naked; with ſhorter branches. Firſt leaves lanceolate with a right angle at the baſe, petioled, wrinkled, bluntiſhly ſerrate or acutely

Digitized by Google

acutely crenate, the notches ſeparated by a right angle, ſoft, ſpreading, above ſomewhat wrinkled and dark green, beneath tomentoſe netted veined and pale green. Flowers axillary, ſolitary, one-flowered, ſhortly peduncled, directed one way. Calyx like that of Ocymum or Scutellaria, with the upper lip cordate, recurved at the edge, acute; lower four-toothed, equal. Corolla white, or ſcarcely fleſh-coloured; without any upper lip, the lower lip trifid, with the middle lobe larger, recurved, emarginate but ſcarcely crenate. Stamens hardly longer than the throat: filaments hairy; anthers brown with ſaffron-coloured pollen. Stigmas acuminate, ſcarcely longer than the ſtamens [b].

Native place not known. Conjectured to be the Eaſt Indies.—Introduced in 1777, by Monſ. Thouin. It flowers from june to october [c].

20. Stem four-cornered, erect, a foot and half high, ſmooth, little branched, annual or perhaps biennial. Leaves obtuſe, inodorous, oppoſite. Peduncles one-flowered, axillary, ſolitary, oppoſite. Flowers ſmall, inodorous. Corolla white: the middle ſegment of the lower lip ſubovate, acute and large; the lateral ones ovate-acuminate. Seeds black.

Native of Cuba in moiſt hedges and meadows; flowering in december and the following months [d].

Miller deſcribes his chamædrifolium, which ſeems to be the ſame plant, thus—] Annual, with an erect ſtalk a foot and half high, four-cornered and ſmooth. Leaves about an inch and half long, and three quarters of an inch broad, upon ſhort foot-ſtalks. Flowers axillary, two at each joint, upon ſhort ſlender peduncles: calyx ſhort, cut at the brim into five very acute points: corolla ſmall and white. They appear in july, and the ſeeds ripen in autumn. It was diſcovered by Dr. Houſtoun at La Vera Cruz.

[21. The whole plant is obſcurely pubeſcent. Stems ſuffruticoſe. Spike terminating, like that of T. hircanicum, but ſhorter and yellowiſh. Its native place not known [e].]

22. This is a perennial plant, very like our Scorodonia or Wood Sage; but does not creep at the root as that does; the ſtalks are erect: the leaves are white on their under ſide, and deeply ſerrate; flowers yellow in terminating racemes.

[The plant from Canada has narrower leaves, equally ſerrate, tomentoſe beneath, flat: the ſpike is compoſed of whorls or ſcattered flowers, with a very ſmall bracte under each. But the garden plant has larger wrinkled leaves, unequally ſerrate, ſcarcely pubeſcent beneath; and flowers in a ſubſpiked raceme, of ſix-flowered, ſix-leaved whorls, with ſerrate bractes [f].

Native of North America. Cultivated in 1768 by Mr. Miller. It flowers in auguſt and ſeptember [g].]

23. This is alſo a perennial plant. The ſtalk is annual, riſes near a foot high, and is terminated by a long ſpike of red flowers, which appear in july and auguſt.

[Schreber could not diſcover the two lipped calyx and doubly-crenate leaves of Gouan: nor do Medicus's ſpecimens correſpond with Gronovius's deſcription [h].—Native of Virginia.

24. This ſeldom riſes above two feet and a half in height; the ſpikes of flowers are ſtiff, ſtraight and thick. It is a native of Jamaica, and pretty frequent in the lower parts of St. Mary's, where it grows very luxuriantly [i]. It was introduced here in 1778, by William Wright, M. D.; and flowers from auguſt to october [k].

Mr. Miller has a ſpecies, which he names veſicarium (n. 17.) But whether it be the ſame with this I am not able to ſay. He thus deſcribes it.] It is an annual plant, with a ſlender, upright, four-cornered ſtalk which riſes three feet high, and divides into ſeveral ſmooth branches. Leaves ovate-lanceolate, three inches long, and an inch broad, bright green on their upper ſide, but pale on their under, unequally ſerrate, upon long foot-ſtalks. Flowers axillary and terminating, in long bunches; they are pretty large, white, and have bladdered calyxes.

[25. Leaves like thoſe of Betonica officinalis. Spikes very long, with the flowers thickly heaped ſpirally on every ſide, from the laſt forkings of the ſtem [l].

Native of Perſia. Introduced in 1763, by John Earl of Bute. It flowers from auguſt to october. Perennial [m].

26. Leaves very large, like thoſe of Sida. Teeth of the calyx very blunt. Structure of the corolla almoſt as in T. betonicum; colour yellow [n].

Native of Madeira, where it was found by Maſſon, and introduced in 1777. It flowers in april and may [o].

27. Root perennial, creeping. Stems a foot and half or two feet high, four-cornered, nearly upright, hairy, leafy, hard, often purple, panicle-racemed. Leaves oppoſite, wrinkled, hairy, veiny and wrinkled like Sage, ſomewhat glutinous, ſtrong-ſmelling, bitter. Flowers in pairs, on long oppoſite naked racemes, pedicelled: calyx a little woolly, upper lip broad, bent back, pointed, lower with four very ſhallow clefts terminating in pointed teeth bent inwards: corolla ſtraw-coloured, woolly; tube longer than the calyx, upper lip none, but the top of the tube ſlightly cloven. Stamens violet-coloured. Seeds blackiſh, ſhining, almoſt covered with croſs rigid hairs [p].

Native of Europe and Morocco, in woody and hilly ſituations, among buſhes and under hedges, where the ſoil is dry and ſtony: in ſuch places frequent in moſt parts of Great Britain; flowering from july to ſeptember.

Mr. Laurents, in his obſervations on the huſbandry of Flanders remarks, that in ſmell and taſte, the Scorodonia or Wood-ſage, (which would be more properly named Sage-leaved Germander,) reſembles hops. It is called *Ambroiſe* in Jerſey, and in that iſland, when cyder fails, they malt their barley at home, and inſtead of hops, uſe to very good purpoſe, the *Ambroiſe* of their hedges [q]. Rutty ſays, that when this herb is boiled in wort, the beer ſooner becomes clear than when hops are made uſe of [*]. Dr. Withering relates that upon trial it gave too much colour to the liquor.

28. This has the appearance of the preceding, but differs in having a ſhrubby and more hairy ſtem, with the lower leaves tomentoſe beneath and hoary.

Native of Barbary, on mount Lazar near Mayane in Algiers [r].

29. Stems ſuffruticoſe, ſcarcely a foot high. Leaves ovate or cordate-ovate, unequally ſerrate, bluntiſh, ſmall, reflexed at the edge, veined beneath. Flowers oppoſite, peduncled. Calyxes nearly like thoſe of Scutellaria, as in *T. hircanicum*, with the upper lip ſubcordate, ſpreading, acute. Corolla purple with the lower lip very concave. It has the odour of Nepeta or Cat-mint [s].

According to Loureiro, it is three feet high, whitiſh, ſmooth. Leaves acute, deeply crenate. Flowers violet-coloured, in erect terminating ſpikes. Calyx ovate, five-cleft [t].

Native of the South of France, Candia, and Cochinchina. In the latter, the inhabitants boaſt much of its medical qualities. It was cultivated in 1731 by Mr. Miller, and flowers in june and july [u].

30. This is a handſome underſhrub, about three feet high. Stem upright, branched, round, cloven, cinereous: branches oppoſite, ſpreading, flowering and brachiate at the top: ſhoots four-cornered, hoary-green, pubeſcent. Leaves oppoſite, broad-lanceolate, ſharp at both ends, ſerrate but entire at the baſe, ſparingly nerved, the midrib and veins prominent beneath, marked with lines above, beneath glaucous and ſoftly ſubpubeſcent, flat, ſpreading very much, the older ones reclining, from two to four inches long. Petioles three times ſhorter than the leaves, round, cinereous or hoary, ſubpubeſcent. Racemes terminating and at the ſame time from the axils of the

upper

Digitized by Google

upper leaves, digeſted into a ſort of brachiate panicle, erect, peduncled, ſimple or in a manner ternate, bracted, pubeſcent, from four to ſix inches long. Flowers oppoſite, pedicelled, in the axils of the bractes, ſolitary, ſpreading, ſmelling like apples, purple. Bractes oppoſite, ſeſſile, lanceolate, entire, ſpreading very much, longer than the pedicel, of the ſame colour with the leaves. Seeds wedge-ſhaped, angular on one ſide, round on the other, hirſute, cinereous[x].

Native of Madeira. Introduced in 1775 by Sir Joſeph Banks. It flowers from may to auguſt[y]. Monſ. L'Heritier ſays, it was found in the ſame iſland alſo by Maſſon, and introduced by him into England, and thence into France.

This ſpecies, heterophyllum and abutiloides are intermediate between Teucrium and Ajuga. Perhaps on account of the tube of the corolla being very much lengthened out, and the upper lip ſcarcely emarginate and not cloven, they would more properly range with the Ajugas, unleſs we ſhould ſink that genus in Teucrium[z].

31. Root perennial, creeping. Stems ſpreading or even proſtrate, little branched, four-cornered, grooved, leafy, hairy. Leaves numerous, oppoſite, ſeſſile, tapering and entire at the baſe, ſerrated upwards, hairy; at the top of the branches, they are ſometimes oval-lanceolate and nearly entire. Flowers axillary: the lower ones frequently ſolitary, the upper in pairs, pedicelled. Calyx hairy, purpliſh, with five nearly equal teeth. Corolla pale purple or pink, ſmaller and leſs handſome than thoſe of Chamædrys[a].

Native of many parts of Europe. In England not common. Mr. Ray obſerved it plentifully in the fens of the Iſle of Ely. I gathered it in the way from Cambridge to Hiſton on the firſt of auguſt 1760. It is found alſo at Waterbeach, Cottenham, &c. Dr. Sibthorpe gathered it on the banks of the Iſis near High-bridge, and on Eynſham-common, Oxfordſhire. It flowers in july and auguſt.

The freſh leaves are bitter and ſomewhat pungent. Powdered they deſtroy worms. A decoction of the plant is a good fomentation in gangrenous caſes[b]. It has a ſtrong diſagreeable ſcent, ſomewhat approaching to Garlick; whence its name of Scordium (from Σκορδον, Garlick). It was once in high eſteem as an antiſeptic and alexipharmic, to which it certainly had no claim. Bergius ſtates it to be antiputredinous, tonic, diaphoretic, diuretic and reſolvent. Others recommend it to be employed externally in antiſeptic cataplaſms and fomentations. Cullen ſays, it has a bitter, joined with ſome volatile parts, but that neither of theſe qualities is conſiderable enough to retain it in the preſent practice[c].

Sheep and goats are ſaid to eat this plant: horſes, cows and ſwine to refuſe it. If cows compelled by hunger eat it, their milk gets a garlick flavour[d].

32. Root perennial, creeping. Stems buſhy, almoſt upright, ſix or eight inches high, round, leafy, hairy. Leaves hairy, attenuated at the baſe, where they are entire, in the other parts deeply cut: from each axil a bunch of ſmaller leaves. Flowers from the upper axils, often three together, but ſometimes ſingle, oppoſite, pedicelled, forming a leafy ſpike. The upper part of the ſtem and the calyx are duſky purple. The upper ſegment of the calyx is broadeſt, the two lower ones narroweſt, beſet on the outſide with white globules. Corolla reddiſh purple, with white globules alſo on the outſide. Seeds naked[e].

Retzius deſcribes the ſtems as decumbent, with ſtraight diſtinct hairs; the leaves acute, gaſh-ſerrate, rough-haired on both ſides, about the length of the internodes. Bractes hairy on both ſides; the lower like the leaves; the upper quite entire, concave, acute; thoſe in the middle with fewer ſerratures. Flowers directed one way; the lower by twos, the upper by threes from each bracte. Calyx hirſute. Corolla pale purple, with the lower lip truncate, hollow. Genitals purple. Withering alſo affirms that the lower lip is truncate: but it is not ſo in the garden ſpecimens now before me; nor are the leaves hairy on the upper ſurface.

Native of many parts of Europe, the iſlands of the Archipelago, and Paleſtine near Jeruſalem. In England ſcarcely indigenous, being found chiefly on ruins of old buildings. Ray mentions his having found it more than once, but doubted whether it grew ſpontaneouſly. James Sherard found it plentifully on the ruins of Winchelſea Caſtle. Dr. Stokes, in the area of Cariſbrook Caſtle in the Iſle of Wight. Mr. Dickenſon, on the rubbiſh of Whittington Caſtle, near Oſweſtry, in Shropſhire. Mr. Crowe and Dr. Smith, on Norwich city-walls, between Magdalen and St. Auſtin gates. Dr. Sibthorp, on walls by Whitney, on the right-hand ſide of the old road leading to Burford. Dr. Abbot, at Warden in Bedfordſhire. The late canon Holcombe, near St. David's.

Ray ſays that it occurs on the borders of corn fields far from any houſe, but ſtill dared not aſſert it to be indigenous.

The Chamædrys or Germander has been eſteemed chiefly as a mild aperient and corroborant: and was recommended in uterine obſtructions, intermitting fevers, rheumatiſm and gout. Of the laſt mentioned complaint the Emperor Charles the Fifth is ſaid to have been cured, by a vinous decoction of it, with ſome other herbs, taken for ſixty ſucceſſive days. It has been employed in various forms and combinations, of which the Portland powder is one of the moſt celebrated inſtances. Its qualities ſeem nearly allied to thoſe of Marrubium or Horehound, and therefore it may be equally uſeful in aſthmatic affections, coughs and infarctions of the lungs[f].

Dr. Withering ſays, that the plant is bitter with a degree of aroma, and may be uſed with advantage in weak and relaxed conſtitutions.

β. Retzius deſcribes this variety, as a lower plant, the ſtems decumbent, and ſomewhat tomentoſe, eſpecially at the joints: leaves obtuſe, leſs deeply ſerrate, ſhining, ciliate near the baſe, longer than the internodes: the manner of flowering, bractes, calyx and corolla as in the other, except that the bractes are blunt, and the colour of the corolla and genitals white. The odour alſo is weaker.

γ. This alſo is deſcribed as a ſmaller lower plant than the common, with procumbent and more hairy ſtems; the leaves ſmaller and of a paler green; the calyxes more hairy, greener, and not at all tinged with purple[g].

33. This is eaſily known by its heterogeneous leaves, of different colours on the ſeveral branches. Flowers purple. It is a ſhrub, native of Madeira[h]. Cultivated in 1759, by Mr. Miller. It flowers in june[i].

34. Root perennial, putting forth runners, whence riſe ſtraight ſmooth blackiſh ſtems. Leaves petioled, oblong, acutely crenate, nerved, ſmooth, ſhorter than the internodes. Flowers axillary, two on each ſide, purple. Calyxes brown[k]. It differs from T. Chamædrys, by the ſtem being a foot high, erect, ſmooth; not a palm high, diffuſed and hairy[l].

Stems upright or decumbent, ſimple or ſparingly branched, often purple. Leaves ſhining on the upper ſurface; the lower running into the petiole, bluntly toothed; the upper quite entire, ſharpiſh. Flowers two, four or ſix together, in whorls, moſtly directed one way, on pedicels ſhorter than the leaf, very ſhortly pubeſcent. Calyx oblong, ſomewhat gibbous at bottom, purpliſh, with five ovate, acute teeth. Corolla roſe-coloured[m].

Mr. Miller compares it with the next ſpecies.] It has a ſhrubby ſtalk like that, not riſing ſo high, but branching out more, and covered with a ſhort hairy down: the lower leaves ovate, crenate, of a lucid green on their upper ſide, but a little hoary on their under: the leaves between the flowers ſpear-ſhaped and entire: the ſpikes of flowers much longer, the

Digitized by Google

flowers themſelves larger, and their colour more inclining to a yellow.

[Native of the South of Europe and Mount Atlas.—Cultivated in 1730 by Mr. Miller. It flowers from june to ſeptember[n].

35. Stem ſhrubby, branched, pubeſcent, often procumbent at the baſe. Leaves ovate, ſhining above, pubeſcent beneath, crenate, obtuſe, petioled; the upper ones quite entire. Whorls from two to ſix-flowered, diſtinct. Flowers pedicelled. Calyx pubeſcent tubular, five-cleft: ſegments acute, almoſt equal. Corolla pale yellow: the two upper ſegments long, linear, greeniſh, compreſſing the anthers on both ſides, the middle ſide ones ſmall, acute, ſtraight; the lower lobe ovate, concave, quite entire: tube deeply cloven at top. Filaments bowed. Anthers ſaffron-coloured[o].

Schreber is of opinion that the ſynonym from Moriſon does not belong to this ſpecies.]

According to Miller it is two feet high, and ſends out many woody branches. Leaves a little waved, little more than an inch long, and three quarters of an inch broad near the baſe, upon ſhort foot-ſtalks. The upper part of the branches for ſix or eight inches are adorned with flowers from the axils, two or three from each joint; they are of a dirty white colour, and appear in july; under each whorl ſtand two ſmaller leaves, which are entire and concave.

[β. The hairy variety remarked by Desfontaines, has the whorls cluſtered; the bractes and calyxes very villoſe.

Native of the South of Europe, and of Barbary.—It appears from Parkinſon that it was cultivated here in 1640[p].

36. Stem branched. Leaves like thoſe of T. hircanicum, obtuſe, petioled, pubeſcent. Whorls from four to ſix-flowered. Flowers on ſhort pedicels. Calyx villoſe, oblong, five-toothed: teeth ovate, acute, almoſt equal. Corolla purple, the ſame ſize as in T. Scordium. Stamens ſtanding out, on bowed filaments. Bractes ſix to eight, whorled, ovate, acuminate, petioled, villoſe: the lower ones toothed; the upper ones quite entire. It flowers early in the ſpring, and is found on the uncultivated hills near Maſcar and Tlemſen[q].

37. This and the following ſpecies are treated ſeparately by Miller, under their old name of Polium. Of theſe he has fifteen ſpecies, ſome of which are varieties, and others not taken up by Linneus.

Mr. Miller thus deſcribes this ſpecies] Root compoſed of many woody fibres, which ſpread wide. Hence ariſe ſeveral weak trailing, woody ſtalks eight or nine inches long, ſending out many branches. Leaves ſmall, of a deep green. Flowers white, appearing in june and july; but ſeldom ſucceeded by ſeeds in England. There is another ſort (or variety) with much ſmaller leaves, hoary on their under ſide.

[Native of Germany, France, Switzerland, Auſtria, Piedmont.—Cultivated in 1711, as appears from Salmon's herbal[r].

38. This is allied to the preceding. Leaves quite entire, acute, in cluſters. Flowers white[s]. It is the ſecond Polium of Miller's ſecond volume of his Dictionary publiſhed in 1739; and was therefore at that time cultivated by him[t]: but he omitted it in the later editions of his book.

Jacquin deſcribes it as having a perennial woody root. Stems many, ſpread in a ring, ſhrubby. Branches round, annual, aſcending, half a foot long, appearing villoſe with a magnifier. Leaves lanceolate-linear, ſharpiſh, quite entire, ſubſeſſile, ſmooth and green above, wrinkled and hoary beneath, ſlightly rolled back at the edge. Heads of flowers cloſe, erect; pedicels very ſhort, but lengthened in fruiting. Calyx mucronate, often tinged with purple. Corolla white.—Native of Auſtria, in mountains.]

39. This has ſlender ſhrubby ſtalks, which trail cloſe upon the ground; they have a purple bark, and

[n] Hort. kew. [o] Desfontaines. [p] Hort. kew. [q] Desfontaines. [r] 880, n. 3. Hort. kew. [s] Linn. ſpec. & ſyſt. [t] Hort. kew.

are covered with white hairs: the leaves are round at the top, but at their baſe are contracted in form of a wedge, ſo as to reſemble at firſt ſight the leaves of Ground-Ivy, but they are hairy, and of a thicker conſiſtence: the flowers are collected in round bunches at the end of the branches; the corolla is large, and one half of it is purple, the other white. It flowers great part of the ſummer, but ſeldom produces ſeeds here. It grows naturally on the Pyrenean mountains. [Cultivated in 1731, by Mr. Miller[u].

40. Stems ſuffruticoſe, round, procumbent. The whole plant tomentoſe and hoary. Leaves oblong, lanceolate or almoſt linear. Flowers ſeſſile, cloſe and lying over each other, ſmall. Bractes the length of the calyx. Corolla yellow: the middle ſegment concave, entire[x].

Native of the South of Europe, the Levant, and Barbary.—It appears from Turner's herbal, that it was cultivated here in 1562[y]. Linneus has ſeveral varieties, ſome of which other authors conſider as diſtinct ſpecies. Mr. Miller has multiplied the varieties very much.]

α. The common Yellow Poley has the ſtalks rather herbaceous and trailing, about ſix inches long and hoary: leaves woolly, about half an inch long, ſome wedge-ſhaped, others oblong ending in obtuſe points, and crenate towards their ends: flowers collected in oblong thick ſpikes at the end of the branches, of a deep yellow colour, and appearing at the beginning of june. It grows naturally in Spain.

Narrow-leaved Yellow Poley (n. 3.) has woody ſtalks, erect, branching, and covered with a hoary down, riſing ſix or eight inches high: leaves linear, woolly, about half an inch long, having ſometimes two or three ſlight indentures on their edges: flowers collected in roundiſh ſpikes at the end of the branches; they are bright yellow, have woolly calyxes, and appear in june and july. This grows naturally in Spain and Portugal.

[Schreber ſeparates this under the name of Teucrium aureum; and Villars, under that of T. tomentoſum. According to the latter it is ſmaller than the white, the ſtems more cottony, the leaves cut on the ſides and at the end, a little like thoſe of the Chamædrys, but as ſmall again, of a deep yellow, and the lower lip hollowed like the bowl of a ſpoon and lengthened out: the whole plant is covered with a yellowiſh cotton, which is more apparent at the top where the flowers are.

β. According to Villars the White Poley is intermediate between the preceding variety and the capitatum, which is our next ſpecies. The ſtems are a foot long and trailing; the leaves are a little cottony, entire on the ſides, but toothed at the end; the flowers are pretty large, white tinged a little with purple.]

Miller deſcribes it, as having a trailing branching ſtalk, which at the bottom is woody, but the branches herbaceous and woolly: the leaves linear-lanceolate and woolly, indented on their edges: the flowers produced in a corymb at the end of the branches, ſmall and white; appearing in june and july. It grows naturally in the South of France and in Italy.

Some of his other ſpecies may probably be reduced to this: as Polium latifolium, n. 7. which has a woody erect branching ſtalk, near a foot high, very hoary, and branching out towards the top; the leaves lanceolate, indented on their edges, and woolly on their under ſide; the flowers white, ſmall, and growing in cluſters at the end of the branches. This and the next flowers in june and july, and grow naturally in Italy and Spain.

P. erectum, n. 8. riſing with a ſhrubby ſtalk nine or ten inches high, branching out towards the top in form of a corymb; the leaves linear, and reflexed on the edges; the flowers collected in roundiſh woolly heads at the end of the branches, white and ſmall.

And perhaps P. ſpicatum, n. 10. which has ſlender ſhrubby ſtalks, riſing a foot and half high, ſmooth and white ſending out a few ſhort branches towards the top; leaves ſmall, linear, growing in cluſters;

[u] Hort. kew. [x] Desfont. & Scopoli. [y] Hort. kew.

Digitized by Google

the flowers collected in long cylindrical ſpikes, which ſtand in bunches at the top of the ſtalks, and ſometimes come out in bunches on the ſides; they are ſmall and white, and appear in july and auguſt.—Native of Sicily.

[γ. Villars conſiders this and the next variety, as mere varieties of the album.

δ. This is made a ſeparate ſpecies by Schreber and Willdenow.—Native of the ſhore of the Adriatic [z].

41. Shrubby branched at the baſe. Branches round, tomentoſe, erect. Leaves ſeſſile, linear-lanceolate, obtuſe, often ternate. Flowers corymbed, headed, cloſe. Calyxes villoſe-tomentoſe. Corolla ſmall, pale yellow or white [a].

It has the habit of Origanum Majorana, but it is tomentoſe and has narrow leaves [b].—Native of France, Spain, Barbary and Siberia.]

β. This has an erect branching ſtalk, which riſes a foot high; the lower part becomes woody, but the upper is herbaceous; the leaves are linear-lanceolate, about an inch long, crenate, of a pretty thick conſiſtence, and a little woolly; the flowers collected in a corymb at the end of the branches, white, appearing in july and auguſt.

[According to Villars, it does not creep like the others; the ſtems riſe a foot or more, and are terminated by a lengthened ſpike, which is often interrupted; the villoſe leaves are more pointed, in other reſpects they reſemble thoſe of the white Poley; the flowers alſo are white.

Gerard conſiders this as a variety of T. Polium. Alſo remarks, that beſides other differences, it flowers much later.

Native of the South of France and Italy.—Cultivated by Mr. Miller in 1731 [c].

42. Native of Spain. Tournefort's plant is conſidered as a new ſpecies under the name of Teucrium Libanitis, n. 67.

43. Flowers two axillary peduncled, one from each ſide of the ſpine [d].

Teucrium mucronatum, which Linneus had made a diſtinct ſpecies, is only a variety, with white reſupine corollas, and very ſhort ſtamens [e].

This is an annual plant, native of the hills and fields of Portugal.

44. This is a procumbent ſhrub, allied to T. capitatum: but it has the leaves and calyxes ſcarcely tomentoſe, the peduncles leafy, and the corollas violet-coloured.—Native of Barbary, in the uncultivated fields near Maſcar [f].

45. Herbaceous: the whole plant very ſmooth. Leaves like thoſe of the campanulatum, the uppermoſt three-parted, with the ſegments quite entire. Calyxes bell-ſhaped, five-cleft; the ſegments lanceolate, with a raiſed line along the back.—Native of Buones Ayres.

46. Stems a ſpan high, aſcending, hoary, muricated from the fallen leaves; the younger branches tomentoſe. Leaves on theſe only, ſeſſile, green with a ſlender nap, which is thicker underneath, ſoft, rolled back a little, obtuſe. Peduncles three from the uppermoſt axils on each ſide, the height of the ſtem. There is a ternate leaf at the baſe of each head of the ſame ſtructure with the ſtem-leaves. Calyxes tomentoſe, bluntly toothed.—Native of Spain and Barbary.

47. This is a ſmall ſhrub, covered wholly with a thick white wool, which becomes yelloviſh towards the top, and is very much branched; the branches are proſtrate and diffuſed. Leaves ſeſſile, cluſtered, obtuſe. Flowers at the end of the branches, oppoſite, in cluſters. Calyxes larger than in the other ſpecies, ſubglobular, obtuſe. Seeds wrinkled [g].

It differs from T. Polium, in having ſolitary looſiſh flowers ſcarcely in heads; and not in round heads; the leaves alſo are linear not oblong [h].

Found in Spain, on mountains near Saguntum and Guadalaxara, by Vahl.

[a] Willdenow. [b] Desfontaines. [c] Linn. ſpec. [d] Hort. kew. [e] Linn. ſpec. [f] Linn. ſyſt. [g] Desfontaines. [h] Vahl. [i] L'Heritier.

48. Differs from inflatum by its hairineſs, leaves very hairy on both ſides and narrower, with teeth longer towards the baſe, bractes lanceolate-acute, and teeth of the calyx mucronate.—Native of Tongatabu in Auſtralaſia [i].

49. Stem ſhrubby, upright, round, five feet high, with ſpreading branches. Leaves ovate-oblong, blunt, ſmooth, oppoſite, petioled. Corolla pale, five-cleft, with a ſhort tube, and the ſegments blunt, the upper ones divaricating. Stamens very long.—Native of Cochinchina, by hedges.

50. Stem ſhrubby, eight feet high, ſmooth, round, branched. Leaves ovate-oblong, acute, quite entire, petioled, ſmooth, oppoſite. Flowers white.—Native of Cochinchina among buſhes, where the natives uſe it as tea, to promote digeſtion, and to relieve an overloaded ſtomach [k].

51. Stem four-cornered, rough-haired, branched, leafy. Leaves oppoſite; the larger cut with a lobe, the ſmaller with a ſharp tooth on each ſide, in other parts entire, rugged above, tomentoſe beneath, with a yelloviſh nap ſcarcely perceptible. Peduncles oppoſite, the length of the internodes. Calyx bell-ſhaped, ſpreading, five-toothed: teeth lanceolate, almoſt equal; pubeſcent. Corolla purpliſh, with the lip pubeſcent on the outſide, deeply three-lobed, the middle lobe reflexed, concave, emarginate. Stamens long. Style longer. Stigma bifid, one ſegment ſhorter, both reflexed. Seeds roundiſh, wrinkled, large in proportion to the calyx.—Native of the Cape of Good Hope [l].

52. Like the orientale in the leaves and inflorescence; but differs in having the racemes more elongated, the peduncles longer, and the corollas ſcarcely longer than the calyxes, which in that are much longer. Found by Tournefort in Armenia.

53. This is a ſhrub reſembling Lavandula Stoechas. Leaves hoary on both ſides, rolled back at the edge, veined beneath. Peduncles long, ſolitary, in the axils of the upper leaves. Calyxes hoary, bluntly toothed. Corolla large, pubeſcent on the outſide.—Native of Candia on the coaſt [m].

54. Stem ſhrubby. Leaves ſmall, ſhining, hoary beneath, acute, floral ones the length of the calyx. Corolla purple, with linear elongated earlets.—Native of Spain [n].

55. Stem erect, grooved, ſmooth, a foot high and more: branches from divaricate-erect, rod-like. Leaves acute, ſmooth, pale beneath, an inch or more in length, on petioles only half the length of the leaves. Racemes ſubdiſtich, erect, unequal, the longeſt a finger's length. Bractes lanceolate, acute, entire, ciliate and rugged, a little longer than the peduncle. Peduncles capillary, one-flowered, ſcarcely a line in length. Calyxes angular, ſlightly awned, ciliate and rugged. Corollas narrow, twice as long as the calyx. It varies with doubly ſerrate, unequally ſerrate, and gaſhed leaves [o].

Thunberg took it for the virginicum, to which it is near allied, but leſs in ſtature, with the leaves doubly ſerrate and rounded at the baſe, not gradually attenuated into the petiole: the flowers alſo are ſmaller and drooping, the raceme compound at the baſe, the bractes linear and of the ſame length with the calyx [p].—Native of Japan.

56. Root perennial, woody. Stem erect, pubeſcent, ſomewhat clammy. Leaves unequally crenulate, rounded at both ends, ſilky-hoary above, whitiſh beneath, ſhortly petioled, like thoſe of Sage, but ſmaller. Raceme ſhort. Calyx hairy, half-five-cleft; teeth lanceolate, the upper tooth a little wider than the reſt. Corolla villoſe on the outſide, with a tube the length of the calyx.—Native of Portugal.

57. Root perennial. Stem woolly, higher than in Scordium. Leaves wrinkled, leſs deeply crenate, covered with white wool: branch-leaves ſmaller. Flowers larger.—Native of Candia.

58. Stem ſhrubby, ſmooth, denſely hairy on both

[k] Forſter. [l] Loureiro. [m] Willdenow. [n] Schreber. [o] Willdenow. [p] Retzius. [q] Thunberg.

ſides

Digitized by Google

TEU

ſides from the point where the leaves meet. Leaves on ſhort petioles, entire at the baſe, but cut in front with obtuſe notches bent back at the edge; they are ſmooth and ſhining with the midrib bearded at the baſe, blunt and hard: the floral leaves are almoſt lanceolate, more hairy than in flavum, as are alſo the calyxes. The flowers are ſmaller. Corolla purple, with ſmaller earlets, which are blunt but not truncate. —Native of Barbary.

59. Stem ſhrubby, a finger's length, covered with a white nap, branched. Leaves cluſtered, ovate or ovate-lanceolate, hoary, bent back at the edge and obſcurely crenate all round; they are ſmall and on very ſhort petioles. Flowers four or five, erect, ſeſſile. Calyx even, hoary, mucronate. Corolla purple.—Native of the kingdom of Valentia in Spain.

60. Stem ſhrubby, decumbent or hanging from the rocks. Leaves leſs than in pyrenaicum, ſlightly cut out like reniform leaves at the baſe, the reſt of the circuit almoſt orbicular, deeply and bluntly crenate, bent back at the edge, the upper ſurface green, but covered with ſoft hoary hairs, which on the lower ſurface are denſer and longer, chiefly adhering to the veins and filling the interſtices between them. Corymbs roundiſh, few-flowered. Floral leaves lanceolate, naked above, obtuſe, ſhorter than the calyx. Calyx angular with ten ſtreaks, villoſe, acuminate.—Native of Valentia, on the rocks of the higheſt mountains.

61. This alſo is a native of the kingdom of Valentia on mountains.

62. This is confounded with Yellow Germander, (which is not diſtinguiſhed from the white by Linnæus, but is made a ſeparate ſpecies by Schreber and Willdenow, under the name of aureum.) It agrees with that in ſtature, in the whiteneſs and delicacy of the wool on the ſtem and leaves, and in having the leaves crenate with a narrower entire baſe, which however is wider on the flowering branches: but it differs in having the leaves narrower and lanceolate, (on the young ſhoots linear;) the heads ſmall and few-flowered; the calyx ſhorter, clothed not with hairs, but with a cloſe nap, neither angular nor keeled; the tops not of a gold, but of an elegant ſulphur colour. Schreber ſaw only three conglobate heads at the top of the ſtems. Barrelier has ſeveral lateral ones in his figure.—Native of the South of France.—This is perhaps Polium anguſtifolium of Miller, n. 3.

63. This differs from the white Poley (40. β.) in having a more ſlender ſtalk; the leaves not ſhorter but very narrow, obſcurely crenate, covered with a very thin nap, which is a little cloſer and hoary on the under ſide, blunt at the end; heads numerous, ſmaller, hoary, on almoſt equal leafy branchlets; flowers ſmaller. The floral leaves equal to the calyx, which is covered with a thin whitiſh nap, and has the mouth blunt, more cloſely tomentoſe.—Native of Valentia.

64. Root woody. Stem aſcending, clothed with a thin white nap. Leaves long, narrower at the baſe, cut into ſmall reflexed notches from the middle, wrinkled, green but becoming hoary with a thin nap, more ſo on the under ſurface, obtuſe, the upper ones ſhorter and twice as broad. Heads roundiſh, few-flowered, at the top of the ſtem, and at the ends of the branches, which are elongated and trifid. Floral leaves longer than the calyx. Flowers erect, the lower ones ſpreading. Calyx angular, cloſely tomentoſe. Corolla white. It is larger than T. pſeud-hyſſopus (40. ε.); greener and the flowers bigger; of the ſame ſize as in Yellow Poley (40. α.) The leaves are ſometimes in threes.—Native of Portugal.

65. The whole plant is covered with a very thick white nap. Stem a ſpan high, procumbent at the baſe, with aſcending branches, and very ſhort branchlets, cloſely leafy, ſpringing on every ſide from the axils. Leaves obtuſe, with a few indiſtinct notches towards the tip. Heads ſmall, one terminating and others lateral, on peduncles of a middling length. Floral leaves ovate, obtuſe. Calyx minute, tomentoſe. Corolla white.—Native of Spain[a].

[a] Schreber.

66. Native of Valentia. Shrubby. Leaves narrow-lanceolate or linear.

67. Shrubby. Stem erect. Leaves like thoſe of Roſemary. Spikes ovate or roundiſh, leafy. Flowers red.—Native of Spain[a].

68. Shrubby.—Native of Spain.

69. Shrubby.—Native of the higheſt mountains of the kingdom of Valentia, eſpecially by the Carthuſian monaſtery called *Porta Coeli*, whence the trivial name.]

PROPAGATION AND CULTURE.

1. Sow the ſeeds in the ſpring where the plants are to remain; when they come up, thin them where they are too cloſe, and keep them clean from weeds. They ripen their ſeeds the firſt year, but if they are in a warm ſituation will live through the winter.

3. This is propagated in the ſame way; but if the ſeeds be ſown in autumn, or permitted to ſcatter when ripe, they will ſucceed better than if ſown in the ſpring, and the plants will come earlier to flower.

4. If the ſeeds be permitted to ſcatter, the plants will come up better than if ſown, and require no care but to thin them, and keep them clean from weeds.

5. Part the roots in autumn, or ſow the ſeeds at that ſeaſon. It loves an open ſituation expoſed to the ſun, but will thrive in almoſt any ſoil which is not too moiſt.

7. Sow the ſeeds in autumn, or permit them to ſcatter, in which way they ſucceed beſt.

9, 10. Theſe may be increaſed by cuttings planted in the ſpring on a bed of freſh light earth; ſhading and watering them until they have taken root; and keeping them clear from weeds until the following autumn, when they may be tranſplanted into pots, taking them up with a ball of earth about their roots, and watering them until they have taken new root. During the winter they muſt be kept in the greenhouſe with hardy exotics.

14. This ſort is eaſily propagated by ſlips or cuttings, planted during the ſummer months on a bed of light loamy earth, covering them down cloſe either with bell or hand-glaſſes, and ſhading them from the ſun. When they have made good roots tranſplant them either into ſeparate ſmall pots, or on a warm border, at about ſix inches diſtance every way: ſhading them from the ſun, and watering them until they have taken new root; after which they will require no other care, but to keep them clean from weeds. Theſe plants will live through the winter in the open air, on a dry ſoil and in a warm ſituation, when the froſts are not very ſevere; but in hard winters they are frequently killed, if not protected by mats or other covering.

20. 24. Sow the ſeeds in ſmall pots in autumn, and plunge them into the tan-bed in the ſtove between the other pots; in ſpring plunge them into a hot-bed, which will bring up the plants. When theſe are fit to remove, plant each in a ſeparate pot, plunge them into a hot-bed, and treat them in the ſame way as directed for tender plants from the Weſt Indies.

22, 23. Sow the ſeeds in autumn on a bed of light earth. They may alſo be increaſed by parting the roots, and are hardy enough to thrive in the open air.

27. Wood Sage may be propagated by ſeeds or parting the roots; it will grow in any ſoil or ſituation, but being common in woods and thickets, is rarely admitted into gardens.

29. This may be propagated by ſeeds or cuttings, in the ſame manner as n. 9 & 10. but the plants ſhould have a dry ſoil and a warm ſituation, otherwiſe they will not live through the winter in the open air in England. [A plant or two of this and other doubtful ſpecies, ſhould be kept in the greenhouſe during winter for ſecurity.

30. 33. Theſe may be increaſed both by ſeeds and cuttings; and muſt have the protection of the greenhouſe in winter.]

31. Water Germander may be propagated by its creeping roots, or planting the young ſhoots in the

[a] Cavanilles.

ſpring.

Digitized by Google

ſpring, in the ſame manner as Mint, Penny-royal, &c. and ſhould have a moiſt ſoil.

32. Common Germander propagates very faſt by its creeping roots, and will thrive in almoſt any ſoil or ſituation. Tranſplant it in autumn.

34. 35. Theſe may be increaſed by cuttings in the ſame manner as n. 9. 10. Alſo by ſeeds, which they generally produce in plenty. Sow them on a bed of light earth in april; the plants will come up in ſix weeks, and may be tranſplanted in autumn where they are deſigned to remain.

37 to 41. All theſe are abiding plants; they may be propagated by ſeeds, which muſt be procured from the countries where they naturally grow, becauſe they ſeldom perfect their ſeeds in England. Theſe ſhould be ſown upon a bed of frreſh light earth in the ſpring, and when the plants come up, they muſt be carefully kept clean from weeds; about the middle of july the plants will be fit to remove, when they may be carefully taken up, and part of them planted on a warm border of dry rubbiſhy ſoil, obſerving to ſhade them from the ſun, and water them till they have taken new root; after which they will require no other culture but to keep them clean from weeds. My adviſing theſe and many other aromatic plants, which are natives of the warmer parts of Europe, to be planted in rubbiſh, is founded upon long experience of their abiding much longer, and reſiſting the cold of our winters much better, than when they are in better ground, where they grow much freer, are fuller of moiſture, and therefore more liable to be killed by froſt.

The other part of the plants may be planted in ſmall pots, filled with freſh, light, undunged earth, and placed in the ſhade till they have taken new root; then they may be removed into an open ſituation, where they may remain till the beginning of november, when they ſhould be placed under a common frame, to ſecure them from the froſt in winter, which ſometimes deſtroys theſe plants; by this method the ſpecies may be preſerved.

Theſe plants may be mixed advantageouſly with Marum and other aromatic plants, upon the ſloping ſides of banks expoſed to the ſun, or upon little hillocks in a ſheltered ſituation, where by the variety of their hoary branches they will make a pretty appearance, and reſiſt the cold much better than when they are planted in a good ſoil.

They may alſo be increaſed by cuttings or ſlips, planted at the beginning of april, juſt before they ſhoot, upon a border expoſed to the eaſt: if the ſeaſon prove dry, they muſt be watered and ſhaded until they have taken root; and being kept clean from weeds, at Michaelmas the plants ſhould be removed where they are deſigned to remain. But it will be proper to put a plant of each ſort in a pot, that they may be ſheltered in winter.

[TEUCRIUM. See *Ajuga, Bartſia, Dryas, Prafium, Scutellaria, Trichoſtema, Veronica.*

THALIA. (*So named by Linneus, in memory of John Thalius, a phyſician at Nordhuys; author of* Plantæ Hercyniæ, 1588.)

Lin. gen. n. 8. *Reich. n.* 8. *Schreb. n.* 10. *Juſſ.* 63. Cortuſa. *Plum.* 8.

Claſſ. 1. 1. Monandria Monogynia.

Nat. order of *Scitamineæ. Cannæ* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth*, ſcales three, very ſmall, ovate, ciliate, permanent, crowning the germ.

COR. *Petals* five, ſuperior, ſhrivelling, in a double row: *three outer* longer, oblong, waved, connate at the baſe, ſpreading: *two inner* ſmaller, from erect ſpreading, oblong, connate with each other and the nectary at the baſe.

Nectary petal-ſhaped, oppoſite to the ſmaller petals, lanceolate, acuminate, concave.

STAM. *Filament* one, awl-ſhaped, inſerted into the nectary. *Anther* club-ſhaped.

PIST. *Germ* turbinate, crowned with the calyx. *Style* filiform, bent in. *Stigma* leafy, bent in.

PER. *Drupe* oblong, gibbous, one-celled.

SEED one, awl-ſhaped, bent in. (*Nut* bony, two-celled?)

ESSENTIAL CHARACTER.

Cal. three-leaved. *Cor.* five-petalled: two inner petals leſs. *Nect.* lanceolate, concave. *Drupe* with a one-celled nut.

SPECIES.

1. Thalia geniculata.

Corollas five-petalled, nectary lanceolate.

2. Thalia cannæformis.

Lin. ſpec. ed. Willd. 1. 16. *Forſt. prodr. n.* 3. *Symes Ava* 473. *cum ic.*

Corollas ſix-petalled, nectary bifid erect.

DESCRIPTIONS, &c.

1. Leaves alternate, ovate-oblong, with tranſverſe parallel nerves: petioles round, furniſhed with a joint, below membranaceous and ſheathing[s].

Stem taller than a man, quite ſimple. The American Indians uſe it for a dart wherewith to kill animals[t].

The ſynonyms from Browne, Sloane, Ray, Plukenet and Bauhin appertain to Maranta arundinacea.

Linneus, not having ſeen this plant, made out the character from Plumier's figure.

Rottboell's plant, referred to above, is perhaps different from this, and ſeems to be very nearly allied to the next ſpecies[u].—Native of South America.

2. Culm ſolid, round, ſmooth, branched. Branches jointed, divaricating. Leaves on the ſtem, alternate, ſpreading, oval, quite entire, ſmooth, with numerous lateral, aſcending, parallel nerves. Petiole jointed, round above, membranaceous below, ſheathing, embracing, oppoſite to a branchlet. Stipule ſolitary, oppoſite to the petiole, often the length of the ſheaths, awl-ſhaped, channelled at the back: beſides this, there are ſometimes ſcattered ſtipules below the leaves. Panicle pendulous, oppoſite to a leaf: rachis flexuoſe, jointed, compreſſed; joints glume-bearing at the end: glumes two-valved, two-flowered, permanent, involving the peduncle; lower valve length of the peduncle, harder, embracing the upper, which is thinner and coloured: peduncle coloured, club-ſhaped, bifid, fleſhy: flowers white, ſolitary, ſitting on the tips of the pedicel; each having the rudiment of another at the baſe. Calyx three-parted, ſuperior, very ſhort, coloured: ſegments erect, acuminate. Corolla one-petalled, irregular: tube three-cornered: border double; three outer ſegments equal, lanceolate, ſpreading, acuminate, waved; of the inner ſegments two wider, ſpreading; the third ſhort, cowled, covering the genitals. Filament petaloid, two-parted: ſegments ſickled-ſhaped. Anther club-ſhaped, growing to the margin of the right ſegment of the filament. Germ inferior, ſmall. Style cylindric, length of the filament, growing to the tube of the corolla at the baſe, curved in at the tip, free. Stigma concave[x].

Native of Mallicollo, one of the New Hebrides, in Auſtralaſia; and found in the Andaman iſles, and Rangoon, in the kingdom of Pegue, by Dr. Buchanan[y].

Seeds even; leaves tripinnate, pinnules gaſhed ſerrate.

DESCRIPTIONS, *&c.*

1. The root conſiſts of a few ſimple fibres, and creeps juſt below the ſurface by horizontal runners. It is a delicate little plant, ſcarcely a ſpan high, and truly alpine. Root-leaves on long purpliſh foot-ſtalks, firſt ternate, and again either ternate or pinnate; leaflets roundiſh or wedge-ſhaped, varying much in breadth, with ſeveral blunt notches or lobes, ſhining green above, glaucous beneath, often purpliſh, ſmooth, veiny, a little revolute. Stem ſimple, erect, round, about twice as long as the leaves, glaucous or purpliſh, ſmooth, naked or more luxuriant ſpecimens having one ſeſſile leaf, more or leſs compound, about the middle. Raceme very ſimple, at firſt drooping, but afterwards erect, compoſed of eight or ten alternate flowers, each on a ſlender pedicel ſubtended by a ſimple bracte, of which ſome of the lowermoſt approach to the texture and colour of the leaves; the reſt are membranous. Petals four, acute, white or purple. Stamens eight or ten, (Linneus ſays twelve,) capillary, often purpliſh, with oblong vertical anthers. Germs two or four, ſcarcely ever more, (Linneus ſays eight,) roundiſh, green; each with a whitiſh, lanceolate, divaricated, downy ſtyle, or rather ſeſſile ſtigma. Seeds almoſt even.

Native of Lapland, Wales and Scotland, in wet black mould in the clefts of rocks, or on the ſpongy margins of little rills, on very high mountains, and not rare in ſuch ſituations. It is perennial, and flowers early in ſummer [a].]

2. Stem about ſix or ſeven inches high. Leaves downy, compoſed of a great number of ſmall leaflets, which are bluntly indented, and have a fetid ſcent. Flowers in looſe panicles, ſmall, and of an herbaceous white colour. [Haller ſays it has all the habit of Thalictrum minus, and can ſcarcely be diſtinguiſhed from it: but it has a ſmell like that of Geranium Robertianum, approaching to that of cat's urine; the leaves are ſomewhat hairy on both ſides, pulpy and ſofter; the petals themſelves are ſomewhat hairy, in the young plant they are reddiſh, but in the adult whitiſh; it is alſo lower, almoſt a foot high, and leſs leafy.

Native of the South of France, Switzerland, the Valais and Piedmont.

Cultivated by Mr. Miller in 1739. It flowers from may to july [a].]

3. This has knobbed roots. Leaves ſmall, obtuſe, indented in three parts at their points, of a grayiſh colour and ſmooth. The ſtalks riſe a foot and half high, and are naked almoſt to the top, where they divide into two or three ſmall ones, under each of which is placed one leaf, every diviſion is terminated by a ſmall bunch of pretty large flowers, diſpoſed almoſt in form of an umbel, each compoſed of five white petals.

[Native of Spain. Cultivated here in 1713. It flowers in june [b].

Loureiro has a ſpecies, which he names *Thalictrum ſinenſe.* The root is a roundiſh, ſolid and very white tuber; but he ſays it differs from this in the form both of the root and leaves. The ſtem is ſuffruticoſe, quite ſimple, a foot high, round and ſtraight: the leaves linear-lanceolate, quite entire, ſmooth, ſeſſile, alternate: the flowers white, ſolitary, terminating: the petals five, rounded, ſpreading.—Native of China.

4. Height three feet. Stems ſuffruticoſe, dark purple, branched. Leaves reſembling thoſe of Columbine, but glaucous. Flowers in many pale-purple heads, five-petalled [c], white.

There is a variety of this, which is ſomewhat ſmaller, and has pale purple filaments, which in the other are white [d].

Native of North America. Cultivated in 1683, by Mr. James Sutherland. It flowers from may to july [a].

5. Height ſcarcely a foot. Stem ſtraight. Leaflets nodding, by which mark the plant is very diſtinguiſhable in its habit. Flowers four-petalled, with about forty white ſtamens, with yellow anthers. Styles in the female flowers briſtle-ſhaped, longer than in the other ſpecies [e].]

The ſtalks are naked to the top, where they have one leaf, compoſed of many leaflets of a grayiſh colour, indented at their points. The flowers are produced in ſmall terminating bunches.

[Native of North America. Cultivated in 1759 by Mr. Miller. It flowers in june and july [a].

6. Stems four feet high and more, round, upright, the thickneſs of a finger at the baſe, hollow, leafy, branching very much, purple below, ſmooth. Sheaths of the leaves ſtriated. Petioles round. Leaves wide, many-pinnate: leaflets like thoſe of Columbine, ſmooth on both ſides, veined, obtuſe, gaſhed above, deep green on the upper ſurface, and glaucous on the lower. Flowers panicled, ſweet-ſmelling: petals four, oblong, obtuſe, concave, pale, ſpreading very much. Filaments twelve to fourteen, twice as long as the petals. Piſtils from three to five. Seeds lanceolate, acute, brown, ſtraight, ſomewhat ſtriated. It flowers from the middle of june to the middle of july.—Native of Hungary [b].

It approaches in habit to Th. minus, but is of a larger ſtature, with wider leaflets leſs deeply cut, and the flowers are erect not drooping [f].

7. This is neareſt related to the minus, but it is twice or thrice as large. The leaves are broader and more lobed, of a dark green above and glaucous beneath. Stem purpliſh, panicled, the flowering branches growing two or three together, the partial flower-ſtalks generally umbellate. Flowers drooping, with

[a] Engl. bot.

[a] Hort. kew. [b] Idem. [c] Raius ex Cornuto. [d] Moriſon & Parkinſon. [e] Hort. kew. [f] Linn. ſpec. [g] Hort. kew. [h] Jacquin. [i] Willdenow.

four

four purpliſh-green petals. Stamens capillary, with long yellow anthers. Germs furrowed, with ſeſſile downy ſomewhat arrow-ſhaped ſtigmas [k].

Crantz, who ſeems firſt to have deſcribed this plant, particularly notices its differing from Th. minus, in its branches growing three together, the darker colour of its leaves, the grayer green of their under ſurface, and their pellucid veins.

Dr. Withering ſays, that in the ſpecimen before him, the leaves were trebly winged, the leaflets urn-ſhaped and three-cleft at the end, the petals four and purpliſh, the ſtamens fourteen to eighteen, and the piſtils from five to ſeven.

According to Jacquin, the ſtamens are from fifteen to twenty, and the piſtils from four to ſeven. He obſerves that it approaches to the ſibiricum, but in that the fruit is different, the ſtem is green not purpliſh, the leaflets are finely ſerrate and very much ſmaller than even thoſe of Th. minus [l].

Native of Auſtria and Hungary in woody places. It has lately been diſcovered in England by Mr. Robſon, on a buſhy hill at Baydales near Darlington, and alſo on the margin of Ullſwater in Cumberland. He ſays that it frequently attains the height of four or five feet. It flowers in june and july.

Dr. Smith remarks, that Dodonæus's figure referred to under Th. flavum (n. 15.), and copied in Ger. emac. 1251. 1. bears a much greater reſemblance to this than to that ſpecies.

8. This is a middle ſpecies between majus and minus, differing in leaves and ſtature from elatum, with which it agrees in the fructification. The whole plant is ſmooth; the ſtems are two feet high and obſcurely angular; the lower leaves are many-pinnate, with oblong ſharpiſh leaflets, having few gaſhes, and pale green beneath. Native of Hungary on hills [m].

Willdenow remarks, that it differs from the minus in having the leaflets wedge-ſhaped, the upper ones undivided and lanceolate, and the flowers almoſt upright never truly drooping.

9. Root fibrous. Stem almoſt upright, a foot high, flexuoſe, grooved; glaucous with a blueiſh bloom, leafy, panicled. Lower leaves very large, patulous, tripinnate almoſt from the baſe; leaflets cordate or wedge-ſhaped, trifid, ſometimes gaſhed, ſmooth, glaucous. Panicle ſpreading, compound. Flowers pedicelled, drooping. Petals four, elliptic, glaucous-purple. Seeds grooved [n].

Mr. Woodward remarks, that the leaflets are broad and blunt, generally trifid at the extremity, though the upper ones are oval-lanceolate and entire; and that the panicle is branched, bearing a few ſcattered flowers at firſt nodding, but afterwards erect.

Pollich numbered twenty ſtamens; and four or five germs as far as nine. Krocker, eighteen or twenty ſtamens, and three, four, five to eight piſtils. Villars reckons as far as twenty-four ſtamens.

Linneus's character of ſix-parted leaves has puzzled many perſons; Dr. Smith interprets it to mean, that the leaves are compounded in a ſix-fold order, which is generally near the truth; not, as ſome have underſtood it, that the leaflets are in ſix diviſions, which can never be the caſe, unleſs by accident, as they have a central lobe, and conſequently an odd number of diviſions.

Native of many parts of Europe, in meadows. In Britain, it occurs in various parts of the country in calcareous ſoils; but being found only in ſuch it is by no means a common plant. It is alſo met with in Ireland on ſandy ſhores about Newcaſtle near Mourne, and ſeldom flowers before july [o].

β. Lhwyd obſerved it with broader leaves in Wales; but being tranſplanted into Richardſon's garden in Yorkſhire, it proved not to be different. Pollich remarks that it varies with broader, larger and ſmaller leaves.

10. Native of North America. Introduced in 1774, by John Fothergill, M. D. It flowers in july [p].

[k] Engl. bot. [l] Withering. [m] Jacquin. [n] Smith brit. [o] Engl. bot. and Templeton M. S. [p] Hort. kew.

11. This has the habit of Th. minus or purpuraſcens, but the leaflets are ſix times ſmaller and glaucous, the colour of Rue or Fumitory. Stem green, very greatly panicled. Panicle brown at the diviſions. It flowers later, with the flavum and dioicum [q].

Willdenow adds, that the wild plant is only half the ſize of the minus, but in the garden it becomes much larger, and approaches in habit to the medium; from which however it differs in having all the leaflets three-parted, and the flowers drooping.

Native of Siberia and Armenia.—Introduced in 1775, by Monſ. Thouin. It flowers in june and july [r].

Gærtner deſcribes the fructification as conſiſting of from five to eight capſules, which are of a ſpongy coriaceous texture, ſmall, ovate, beaked, grooved, one-celled, valveleſs; containing one ovate ſeed, attenuated above, of a ruſſet bay colour, having a brown tubercle at the baſe. Common receptacle very narrow: the proper one a very ſlender umbilical chord deſcending from the vertex of the capſule to the baſe of the ſeed.

12. This differs from all the preceding ſpecies, which it reſembles by its nodding flowers, in the ſtructure of its petiole. Leaves ſuperdecompound as in the reſt; the lateral leaflets moſtly ovate, acute, quite entire, but the terminating and upper lateral ones trifid or elſe bifid. Petiole much widened at the baſe, with orbicular membranaceous wings toothed at the edge. On the partial petioles of the leaves there are alſo ſmaller orbicular toothed earlets, by which mark this ſpecies is eaſily diſtinguiſhed. Native of Siberia [s].

13. This has the habit of Th. minus, but it is lower by half where that is three feet high. Stem purple without any bloom. Flowers purple. Stamens yellow. It differs from Th. minus in not having the leaflets at all purple at the tip. It flowers earlier. Flowers as in Th. minus; with four petals, fourteen ſtamens, and eight piſtils. Native of Canada [t].]

14. Stems from two to three feet high. Flowers ſmall, collected in terminating panicles, and of an herbaceous white colour.

[Petals four; ſtamens ſixteen; piſtils ſeven [u]. Stamens from ten to twelve, according to Scopoli.

It is allied to the next ſpecies, and in Willdenow's opinion, perhaps only a variety of it, he having frequently obſerved among the ſtems of the cultivated plant, ſome with wider leaves, approaching to thoſe of the flavum.

Native of Germany, Switzerland, Carniola and Italy.—Cultivated in 1739 by Mr. Miller. It flowers in june and july [x].

15. Root yellow. Stem two or three feet high, upright, ſimple below, panicled above, ſmooth, ſo ſtrongly furrowed as to be almoſt angular, leafy. Leaves alternate, twice compounded in a ternate order; their common footſtalk with a ſhort ſheathing baſe, and a toothed intrafoliaceous ſtipule; leaflets ſomewhat wedge-ſhaped, commonly trifid, but ſometimes undivided, entire, varying much in breadth and ſharpneſs, veiny, glaucous beneath. (According to Mr. Woodward, the lower leaflets are very irregular, ſometimes wedge-ſhaped, trifid at the extremity, ſometimes oval, entire or with a ſort of lobe on one ſide; upper leaflets lanceolate, entire or trifid.) Panicle erect, much branched, ſomewhat leafy, contracted, compoſed of many, upright, yellowiſh-white flowers, with yellow anthers. Petals four. Germs ſeſſile, deeply furrowed. Styles none. Stigmas ſhort, oblique, heart-ſhaped, downy [y].

According to Linneus, the flowers have twenty-four ſtamens, and from ten to ſixteen piſtils. Haller ſays, from ſeventeen to twenty ſtamens, and from ſeven to ten or twelve ſeeds. Pollich agrees with him in the number of ſtamens, and ſays that he has reckoned ten germs. Krocker affirms, that there are from ſeventeen or twenty-four to ſeventy and even ninety ſtamens, and from ten to ſixteen piſtils.

Dr.

Digitized by Google

Dr. Smith having compared our ſpecimens with original ones of Jacquin's nigricans from himſelf, found no ſpecific difference between them. Scopoli ſuſpected that they might be the ſame. Jacquin thus deſcribes his nigricans.—Stems three or four feet high, erect, ſtriated, hollow. Baſes of the petioles ſtriated, and dilated into membranes. Leaflets lanceolate, acute, deep green above, paler beneath and wrinkled a little with prominent veins, ſmooth on both ſides, ſome quite entire, others thrice or twice cut, eſpecially in the lower leaves, which are alſo wider than thoſe of the upper ones. Panicle cloſe, terminating, erect. Flowers yellowiſh, odorous, not drooping. Petals four, ſmall, leſs coloured. Stamens ſixteen to thirty. Piſtils from two to five at moſt. Seeds as many, brown, ſubovate.

Native of Europe: frequent with us in wet meadows, and on the banks of rivers and ditches; flowering in june.

A cataplaſm made of the bruiſed leaves is a ſlight bliſter, and has been known to give relief in the ſciatica. The root dyes wool yellow; and has been formerly uſed to cure the jaundice, probably from its colour. Cows, horſes, goats and ſheep eat it, but ſwine are not fond of it.

It has the Engliſh name Meadow Rue from its place of growth, and a certain vague reſemblance to Garden Rue, to which it has no affinity.

The narrow-leaved variety mentioned by Lightfoot, and figured by Moriſon (f. 3.) is neither rare nor important. It is ſtill diſtinct enough from Linneus's anguſtifolium [z].

β. Mr. Miller has a ſpecies, which he names *ſpeciоſum*: it is a mere variety of this. [He deſcribes] the ſtalks as angular and five feet high, better furniſhed with leaves, the leaflets of which are very narrow, ſome ending with two, others with three points, of a bright green colour. The flowers are yellow, and are formed into many panicles which terminate the ſtalks. It grows naturally in the meadows about Montpelier: [according to Willdenow, in Spain.

16. This differs from flavum in having the herb half as ſmall again, the flowers nodding not erect; the petals green not white, the filaments fourteen and purple not ſeventeen and white, the panicle thinner, the leaves narrower; beſides the ſtipules between the firſt ramification of the leaves there are no ſcales, whereas in flavum there is a torn ſcalelet on each ſide [a].

The anguſtifolium of Villars is this ſpecies, as appears from ſpecimens ſent by him to Willdenow [b].

Native of Sweden, Denmark and France.—Introduced in 1778, by Monſ. Thouin. It flowers in may and june [c].]

17. Stems upright, channelled, five or ſix feet high, having at each joint pinnate leaves, compoſed of many linear fleſhy leaflets, which are for the moſt part entire, and end in acute points. The flowers are of a yellowiſh white colour; they appear in july, and are ſucceeded by ſmall angular capſules, with one ſmall oblong ſeed in each, which ripens in auguſt.

[Linneus doubts whether this be ſufficiently diſtinct from T. flavum; and in his quaint phraſeology ſays, that it ſeems to be a daughter of time.—Native of France about Paris, and of Spain. Cultivated by Mr. Miller in 1739 [d].]

18. Root thick, fibrous. Stems taper, riſing three feet high. Leaves like thoſe of Columbine. Flowers in large terminating panicles.

[Petals four, ſtamens ſixty, piſtils ſixteen, according to Linneus; or, as Crantz ſays; ſtamens fifty-ſix or fifty-ſeven, piſtils ſeven, eight, or ten; or, as Haller, ſtamens forty to ſixty, ſeeds ſix to twelve; or, as Scopoli, ſtamens ſixty-five to eighty-five, germs ſeven to nine, twelve and ſixteen.]

It varies with a green ſtalk and white ſtamens, and with a purple ſtalk and ſtamens of the ſame colour.

[Native of Scania, Switzerland, Auſtria, Carniolia, Ingria, Sileſia, the South of France, and Italy.—Cultivated by Mr. Miller in 1731. It flowers from may to july [e].

Retzius refers the atropurpureum of Jacquin to this ſpecies, and profeſſes not to know whither the aquilegifolium of that author ought to be referred. Jacquin thus deſcribes his atropurpureum.—Stems three feet high, ſhining, hollow, round, marked with lines, very dark purple with a glaucous bloom before flowering, afterwards partly dark green. Leaves triternate, leaflets like thoſe of Columbine but ſmaller, veined, ſmooth but not ſhining, dark green above, ſomewhat glaucous and netted beneath, widening towards the end, and there variouſly cut into lobes. Petioles round, firm, ſpreading, purpliſh green. Petals four, roundiſh, blunt, very concave, dark purple and ſtriated on the outſide, white within, caducous. Filaments about ſixty, pale purple. Germs from ten to ſixteen. Fruit ſmooth, pendulous, triangular. It flowers from the end of may to the end of june.

19. This is very like the preceding, but it is lower, and has white flowers. Petals four, ſtamens ſixty, piſtils eight [f]. Willdenow adds, that the ſeeds are by no means contorted, but agree exactly with thoſe of aquilegifolium; the imperfect ſeeds however are twiſted. Native of Siberia.

20. Root-leaves two, ſuperdecompound as in the other ſpecies, but far leſs. Leaflets ovate, obtuſe, often three-lobed. Scape ſcarcely a foot high, ſtriated, leafleſs, ſometimes but ſeldom having a ſingle decompound leaf and a lateral peduncle. Flowers heaped into a ſort of terminating umbel. Petals four, deciduous, rounded. Stamens numerous, with membranaceous filaments, more widening above, fleſh-coloured. Germs ſeſſile. Native of Dauria [g].

Retzius remarks that the ſtamineum of the ſupplement is not at all different from this.

21. Stem with one or two leaves. Both root-leaves and ſtem-leaves three-parted, with bipinnate leaflets: pinnas ſubcordate, three or five-toothed. This ſpecies is very diſtinct by its awl-ſhaped ſtyles, dilated on each ſide at the baſe into a vertical ſemiorbicular wing. Native of Siberia [h].

22. The root conſiſts of many capillary bundles. Root-leaves very many, on long petioles, ternate-ſuperdecompound, ſmooth, erect: leaflets gaſhed, ſerrate, ſomewhat wedge-ſhaped, patulous, paler beneath. Scape ſtriated, erect, divided at top. Flowers in whorls, peduncled. Native of Japan [i].]

PROPAGATION AND CULTURE.

Theſe plants are generally propagated by parting their roots, in ſeptember, when the leaves begin to decay, and they may take freſh root before froſt comes on. They may be planted in almoſt any ſoil or ſituation, provided it be not very hot and dry; but they moſtly prefer a freſh light ſoil, and a ſhady ſituation. Moſt of them creep ſo much as to be troubleſome in a garden; therefore it is better to confine their roots in pots plunged in the ground. The third, fourth and eighteenth, are moſt frequently cultivated in gardens; their roots not creeping ſo much as ſome of the others, and the flowers having ſome beauty to recommend them.

DESCRIPTIONS, *&c.*

1. Root thick, fleſhy, in ſhape of a carrot, blackiſh on the outſide, but white within, bitter and very acrid, with a little aromatic taſte. Stem ſpongy, riſing about two feet high, dividing upwards into two or three ſmall branches, each terminated by a large umbel of yellow flowers.

[Leaves large, villoſe, multifariouſly decompound: leaflets wrinkled, unequal, linear or linear-lanceolate, paler beneath, reflexed at the edge. Petioles round, ſheathing at the baſe. Stem cylindrical, ſmooth and even, the thickneſs of a finger, having a glaucous meal ſcattered over it. Sheaths large, concave, entire at the baſe of the petioles. Umbels large, regular, globular: umbellets diſtinct, round[k]. Fruit compreſſed, ovate-oblong, deeply emarginate at both ends, terminated by the receptacle of the ſtamens which is permanent waved and peduncled, below that with the five calycine leaflets curved upwards like little horns, in the other parts winged, bipartile. Seeds two, with four membranaceous wings, of which the two ſide ones are very wide, longer than the ſeed, the two dorſal ones are very narrow, waved, and the length of the ſeed: between theſe wings are three raiſed longitudinal compreſſed ſtreaks, but not membranaceous: the ventral part is flat without any furrow[l].

Native of Spain, Portugal, the South of France, Italy and Algiers.—Cultivated in 1739 by Mr. Miller. It flowers in june and july[m].

Desfontaines remarked a variety, which had the ſeed only half the ſize of the common one.]

2. The leaves of this ſort are cut into many narrow ſegments, almoſt as ſmall as thoſe of the garden Carrot, but rough and hairy; their ſegments are always oppoſite, and narrower at their baſe than their points. The ſtalks riſe about two feet high, and are terminated by umbels of ſmall yellow flowers which appear in july; theſe are ſucceeded by flat bordered ſeeds, which ripen in the beginning of ſeptember. Native of Spain and Italy.

3. The root of this is about the thickneſs of a man's thumb; the bark is yellow and wrinkled, the inſide white and abounds with an acrid milky juice: the leaves are finely divided like thoſe of Fennel, hairy and ſitting cloſe to the root: the ſtalk riſes from two to three feet high: it is naked, and branches into two or three, each terminated by a ſmall umbel of flowers, which are large, yellow, and appear in july: they are ſucceeded by flat ſeeds, having cartilaginous borders, which ripen in ſeptember. Native of Apulia [and the Levant.

4. Leaves ſhining ſmooth; the primary ones on long petioles, ovate or ovate-lanceolate, quite entire, to which ſucceed others, ternate, quinate or ſeptenate, finally three or four times decompound: leaflets narrow-lanceolate or linear, acute, very ſmooth, ſhining above, pale beneath, decurrent into the petiole. Petioles round, ſheathing at the baſe. Sheath large. Stem thick, ſmooth, erect, ſlightly ſtriated. Umbel hemiſpherical: umbellets diſtinct, round. Sheaths concave, leafleſs at the baſe of the peduncles. Petals pale yellow. Seed elongated, ſemicylindrical, ſtriated at the back, having a yellowiſh membranaceous wing at the edge on each ſide. The bruiſed root is good for reſolving tumours. Native of Barbary[n].]

5. This has a ſlender tap root, ſhaped like that of Parſley. The leaves at the bottom are heart-ſhaped. The ſtalk is ſingle and does not branch; it riſes near two feet high, is of a purple colour and ſlender; at each joint is one ternate leaf, the leaflets ovate and crenate. The ſtalk is terminated by a ſmall umbel of purple flowers, which appear in july, and are ſucceeded by compreſſed channelled ſeeds, ripening in ſeptember.

Native of North America. The ſeeds were ſent to Mr. Miller by Dr. Benſel from Philadelphia. Gronovius thought this plant very like that which is figured by Kæmpfer under the name of Nin-ſi.

[6. Leaves bifariouſly or trifariouſly decompound; with the outmoſt ſegments ſmall, acute, unequal; moſt of them three-toothed at the end, but ſome ſimple. Stem erect, ſlightly ſtriated, ſparingly branched, ſmooth. Umbels flat, peduncled. Umbellets diſtinct. Rays unequal. Univerſal involucre five or ſeven-leaved: leaflets linear, pinnatifid at the end, often three-forked, ſeldom ſimple: partial involucre ſimple, ſlender. Corolla pale yellow. Flowers in the centre male, abortive, ſmaller, on ſhorter pedicels. Seeds ſemicylindrical. Native of Barbary, near Bone by the ſea coaſt[o].

Mr. Miller has two other ſpecies:]

Thapſia maxima, n. 2. which he ſays has a large thick root, of a dark colour on the outſide: the leaves very thick, hairy on their under ſide, ſpreading circularly on the ground, and divided into very broad hairy leaflets: the petioles are decurrent: the ſtalks riſe four or five feet high, are large, jointed and full of pith, having one leaf at each joint, ſhaped like

[k] Desfontaines.

[l] Gærtner. [m] Hort. kew. [n] Desfontaines. [o] Idem.

Digitized by Google

thoſe at the bottom, but ſmaller as they approach the top. The ſtalk is terminated by a large umbel of yellow flowers which appear at the end of june, and the ſeeds ripen about two months after. Native of Spain, all over Old Caſtile, quite to the Pyrenees.

Thapſia altiſſima, n. 6. has a large taper root; the leaves ſpread circularly near the ground, are branched into ſeveral, and theſe again are divided into many very large lucid leaflets, ſtanding alternately on ſhort footſtalks; the ſtalk riſes near eight feet high, and is terminated by an umbel of yellow flowers, which appear in july, and are ſucceeded by bordered compreſſed ſeeds, which ripen in ſeptember.

Thapſia maxima, latiſſima folio *Baub. pin.* 148. is given as a ſynonym of the former; and Th. montana omnium maxima, foliis lobatis *Tilli hort. piſan.* 164. as a ſynonym of the latter.

PROPAGATION AND CULTURE.

Theſe plants are all propagated by ſeeds, which ſhould be ſown in autumn; for if they are kept out of the ground till ſpring, they often miſcarry, or if they grow, they commonly lie a whole year in the ground before the plants come up; whereas thoſe ſeeds which are ſown in autumn, generally grow the following ſpring. Theſe ſhould be ſown in drills, in the place where they are deſigned to remain. The drills ſhould be at leaſt three feet and a half aſunder, becauſe the plants ſpread their leaves very wide. When the plants come up in the ſpring, they muſt be carefully cleared from weeds; and where they are too cloſe together, ſome of them ſhould be drawn out to give room for the others to grow, but at this time they need not be left more than two or three inches apart; for the firſt year when the plants ariſe from ſeeds, they make but ſlow progreſs, the autumn following the remaining part of the plants may be taken up, leaving thoſe which are deſigned to remain about eighteen inches aſunder; and thoſe plants which are taken up may be tranſplanted into another bed, if they are wanted. After the firſt year theſe plants will require no farther care, but to keep them clear from weeds; and every ſpring, juſt before the plants begin to puſh out new leaves, the ground ſhould be carefully dug between the plants to looſen it, but the roots muſt not be injured, leſt it ſhould cauſe them to decay. The plants thus managed will continue ſeveral years. They delight in a ſoft loamy ſoil, and if they are expoſed only to the morning ſun, they will thrive better than if they have a warmer ſituation.

DESCRIPTION, *&c.*

The Tea Tree is commonly about the height of a man. It is deſcribed indeed by different authors as varying much in ſize from that juſt mentioned to thirty and even two hundred feet. Probably it may attain the height of thirty feet or more when left to itſelf; but in general the trees are cut down periodically, that they may make ſtronger ſhoots, and therefore are ſeldom ſeen to be above five or ſix feet high. The trunk is branching and round: the branches alternate or vague, ſtiffiſh, inclining to an aſh-colour, but reddiſh towards the end. Leaves alternate, elliptic, ſmooth, gloſſy, of a firm texture, bluntly ſerrate except near the baſe, blunt and for the moſt part ſlightly emarginate at the end, veined on the under ſide; on very ſhort petioles, round and gibbous beneath, flattiſh and ſlightly channelled above. Stipules to the leaves none. Peduncles axillary, alternate, ſingle, curved, one-flowered, incraſſate, having at the baſe a ſingle ſtipule or bracte, which is awl-ſhaped, erect, elliptic, obtuſely ſerrate, with the edges between the teeth recurved[P]. Corolla white, varying in the number and ſize of the petals. Stamens, according to Loureiro, inſerted rather into the baſe of the corolla than into the receptacle. If ſo, the Tea Tree ſhould be removed into the claſs Icoſandria.

It is thus deſcribed by Thunberg. Stem ſhrubby and arboreſcent, a fathom in height, ſeldom more, ſmooth in all its parts, evergreen. Leaves alternate, oblong-ovate, obtuſe, emarginate, entire at the baſe and thence ſerrate, ſomewhat channelled, parallel-nerved, erect with the end reflexed, thickiſh, deep green above, paler beneath, longer than the interſtices, two inches in length. Petioles half-round, gibbous, a line long. Flowers on the outmoſt twigs, axillary, ſolitary or more frequently two together. Peduncles incraſſate, jointed, drooping, one-flowered, twice as long as the petioles. Perianth five-leaved, green, permanent, much ſhorter than the corolla: leaflets ovate, obtuſe, concave. Petals ſix, white, very blunt, concave, unequal, the three lower being ſmaller. Filaments very many, inſerted into the receptacle, capillary, erect, white, a little ſhorter than the corolla, the outer ones ſhorter than the inner. Anthers round, twin. Germ ſuperior, conical, ſomewhat ſcaly. Style filiform, erect, very ſhort. Stigmas

[P] Lettſom, Linn. ſpec.

three,

Digitized by Google

three, filiform, erect, green, length of the filaments. Capſule tricoccous, often barren either wholly or in one or two of the cells.

Loureiro deſcribes it as a ſmall tree or ſhrub, four feet high, branching very much and twiſted. Leaves lanceolate, acutely ſerrate, thickiſh, incurved, ſubſeſſile, ſmooth, alternate. Flowers white, on terminating, one-flowered, ſolitary peduncles. Calyx five or ſix-leaved, unequal. Corolla compoſed of ſeven, eight or nine petals, which are unequal, concave, ſpreading. Stamens about a hundred, connected at the baſe with one another and with the petals. Style trifid, and equal to the ſtamens; ſegments linear.

Gærtner deſcribes the fruit as a ſuperior coriaceous capſule, ſometimes ſimply globular or made up of two globes, but moſt frequently compoſed of three, three-celled, three valved, on the outſide of a ſmoaky colour, and having diſtant callous dots ſcattered over it. Seeds ſolitary, large, globularly-angular, bay-coloured, with a rounded, wide, cloſed navel on the inner ſide; the ſeed is faſtened to the central angle of the cells.

Native of China and Japan. Introduced about 1768, by John Ellis, Eſq., who raiſed it from ſeed. It flowers here in auguſt and ſeptember. The firſt plant that flowered in England was at Sion, in the ſtove of his Grace the Duke of Northumberland: from this Dr. Lettſom's figure was drawn. Dr. Woodville's figure was taken from a plant which flowered in the ſtove of John Liptrap, Eſq.

Linneus received the true Tea Tree on the third of october, 1763, by Carl Guſtavus Ekeberg, captain of a Swediſh Eaſt-Indiaman, who raiſed it from ſeed on the voyage[1].—It is now to be found in moſt of the curious botanic gardens in England, France, &c. and was introduced into Georgia in America about the year 1770.

I have conſidered all the varieties of Tea as forming one ſpecies. In which I am ſupported by the beſt authorities. Kæmpfer attributes their difference to ſoil, culture, age of the leaves, and method of curing them. Mr. Ellis directly aſſerts that the green and bohea Tea are one and the ſame ſpecies; and that it is the nature of the ſoil, the culture, and manner of gathering and drying the leaves, that makes the difference; and a Green Tea Tree planted in the Bohea country, will produce Bohea Tea, and the contrary. So alſo Sir George Staunton ſays; every information received concerning the Tea plant concurred in affirming, that its qualities depended upon the ſoil in which it grew, and the age at which the leaves were plucked off the tree, as well as upon the management of them afterwards[2].

Linneus, it is well known, diſtinguiſhed two ſpecies of *Thea*; the Bohea with ſix-petalled flowers, and the *viridis* or green with nine-petalled flowers: but it is now well aſcertained that the number of petals is very uncertain; and Dr. Lettſom informs us that he has examined ſeveral hundred flowers both from the Bohea and green countries, and that their botanical characters have always appeared uniform. In the catalogue of the Royal Botanic Garden at Kew, two varieties of Thea Bohea are given, diſtinguiſhed by the leaves; namely *laxa* or broad-leaved Tea, with elliptic-oblong wrinkled leaves, and *ſtricta* or narrow-leaved Tea, with lanceolate flat leaves.—The Bohea Tea trees, now introduced into many botanic gardens near London, exhibit very obvious varieties: the leaves are of a deeper green colour, and not ſo deeply ſerrated; and the ſtalk is uſually of a darker colour; but the botanical characters are the ſame[3].

Thunberg alſo diſtinguiſhes two varieties from the leaves; which in one are ſmaller, flat, darker green, with ſtraight ſerratures, and in the other larger, waved, brighter green, with ſinuate ſerratures: but they can ſcarcely be conſidered as diſtinct ſpecies.

Loureiro's deſcription given above, is taken from a living plant, which he examined himſelf. He obſerved little difference in the Sou-chong, which he alſo examined: both theſe have a brown colour, but are more odoriferous and precious than the common Bohea of the province of Fo-kien, which he had not an opportunity of ſeeing in a living ſtate, though it is the moſt common and cheapeſt of all. He examined the dry flowers of the Green Tea, from the province of Kiang-ſi, and obſerved the ſame inconſtancy, as to the number of parts in the calyx and corolla, as in the Bohea. Upon the whole he concludes that all the differences of Chineſe Tea form only one botanical ſpecies, owing their variation to ſoil, culture, and method of preparation; all retaining the ſame inconſtancy in the parts of the flower, which gave occaſion to Linneus to conſider them as two ſpecies.

Loureiro has two other ſpecies: 1. Thea cochinchinenſis, which both grows wild and is cultivated in Cochinchina, where it is uſed medicinally, eſpecially in hot weather as a ſudorific and refrigerant. The calyx is three-leaved, but ſometimes four or five-leaved, and the corolla five-petalled.—2. Thea oleoſa, a native of China, where an oil obtained from the ſeed is uſed both for the table, and to burn in lamps. The calyx is ſix-leaved, the corolla ſix-petalled, the peduncles three-flowered, and the fruit rather a berry than a capſule.

Many varieties of Tea are known in China, from mixture and management. The diſtinctions chiefly regarded in Europe are the following.

Green Teas.

1. Bing, Imperial or Bloom Tea, with a large looſe leaf, of a light green colour, and a faint delicate ſmell.

2. Hy-tiann, hikiong, hayſſuen or hee-chun. Known to us by the name of Hyſon Tea. The leaves are cloſely curled and ſmall, of a green colour verging towards blue.—Another Hyſon Tea, with narrow ſhort leaves, is called Hyſon-utchin. There is alſo a Green Tea named Gobé, with long narrow leaves.

3. Song-lo or Singlo, which name it receives, like ſeveral others, from the place where it is cultivated.

Bohea Teas.

1. Soo-chuen, ſut-chong, ſou-chong, or ſu-chong, called by the Chineſe ſaa-tyang, and ſact-chaon or ſy-tyann, is a ſuperior kind of Cong-fou Tea. It imparts a yelloviſh green colour by infuſion; and has its name from a place or province in China.

Padre ſutchong has a finer taſte and ſmell. The leaves are large and yelloviſh, not rolled up, and packed in papers of half a pound each. It is generally conveyed by caravans into Ruſſia. Without much care it will be injured at ſea. It is rarely to be met with in England.

2. Cam-ho or Soum-lo, called after the name of the place, where it is gathered. A fragrant Tea with a violet ſmell. Its infuſion is pale.

3. Cong-fou, congo or bong-fo. This has a larger leaf than the following, and the infuſion is a little deeper coloured. It reſembles the common Bohea in the colour of the leaf.

There is a ſort called lin-kiſam, with narrow rough leaves. It is ſeldom uſed alone, but mixed with other kinds: by adding it to Congo, the Chineſe ſometimes make a kind of Pekoe Tea.

4. Pekao, pecko or pekoe, by the Chineſe called back-ho or pack-ho. It is known by having the appearance of ſmall white flowers intermixed with it.

5. Common Bohea or Black Tea, called moji or mo-ee by the Chineſe, conſiſts of leaves of one colour.—The beſt is named tao-kyonn. An inferior kind is called An-kai, from a place of that name. In the diſtrict of Honam near Canton, the Tea is very coarſe, the leaves yellow or browniſh, and the taſte the leaſt agreeable of any. By the Chineſe it is named Honam-té, or Kuli-té.

Beſides theſe, Tea both Bohea and Green is ſometimes imported in balls, from two ounces to the ſize of a nutmeg and of peas. The Chineſe call it Poncul-tcha.—The ſmalleſt in this form is well known under the name of Gunpowder Tea.

Sometimes

[1] Hort. kew. [2] Linn. ſpec. Ellis, p. 28. [3] Embaſſy, 2. 424. [4] Lettſ. p. 41. Compare the figures.

Digitized by Google

Sometimes the ſucculent leaves are twiſted like packthread, an inch and half or two inches long; three of theſe are uſually tied together at the ends by different-coloured ſilk threads. Both Green and Bohea are prepared in this manner.

The Chineſe likewiſe make an extract from Tea, which they form into ſmall cakes not much broader than a ſixpence, or into rolls of a conſiderable ſize. They diſſolve it in a large quantity of water, and aſcribe powerful effects to it in fevers, &c. when they wiſh to procure a plentiful ſweat[u].

The manner of gathering and preparing the leaves, as practiſed in Japan, is fully deſcribed by Kæmpfer, an author on whom we may ſafely depend; and as far as our information reaches, his account is in great meaſure conformable to the method uſed by the Chineſe.

The leaves are gathered carefully one by one, and each perſon is able thus to collect from four to ten or fifteen pounds in one day. The firſt gathering commences about the end of our february or beginning of march, when the leaves are young and tender: they are called Ficki Tsjaa or powdered Tea, becauſe they are pulveriſed and ſipped in hot water: they are diſpoſed of to princes and rich people only, and hence this kind is called Imperial Tea.

A ſimilar ſort is called Udſi Tsjaa, and Tacke Sacki Tsjaa, from the places where it grows. Peculiar care and nicety is obſerved in gathering theſe leaves.

The ſecond collection is made at the end of march or beginning of april. This is called Tootsjaa, or Chineſe Tea, becauſe it is infuſed and drunk after the Chineſe manner.

The third gathering is made in june, when the leaves are full grown. This is called Ban Tsjaa; it is the coarſeſt, and is chiefly conſumed by the lower claſs of people. By ſorting theſe, ſeveral other varieties are produced.

Whether the Chineſe collect the Tea preciſely at the ſame ſeaſons as in Japan, we are not well informed; but moſt probably the Tea harveſt is nearly at the ſame periods, the natives having frequent intercourſe, and their commercial concerns with each other being very extenſive.

The Tea leaves ſhould be dried as ſoon as poſſible after they are gathered. For this purpoſe public buildings are erected, containing from five to ten and even twenty ſmall furnaces about three feet high, each having at the top a large iron pan. There is alſo a long table covered with mats, on which the leaves are laid, and rolled by workmen who ſit round it. The iron pan being heated to a certain degree by a fire made in the furnace beneath, a few pounds of the leaves are put upon the pan, and continually turned and ſhifted by the hands till they become too hot to be endured; they are then thrown upon the mats to be rolled between the palms of the hands; after which they are cooled as ſpeedily as poſſible. In order that all the moiſture of the leaves may be completely diſſipated, and their twiſted form be better preſerved, the above proceſs is repeated ſeveral times with the ſame leaves, but leſs heat is employed than at firſt. The Tea thus manufactured is afterwards ſorted according to its kind or goodneſs. Some of the young tender leaves are never rolled, and are immerſed in hot water before they are dried.

Country people cure their leaves in earthen kettles which anſwer every neceſſary purpoſe, at leſs trouble and expence, whereby they are enabled to ſell them cheaper.

After the Tea has been kept for ſome months, it is taken out of the veſſels in which it was ſtored, and dried again over a very gentle fire, that it may be deprived of any humidity which remained, or it might have ſince contracted.

The common Tea is kept in earthen pots with narrow mouths; but the beſt ſort uſed by the Emperor and nobility is put into Porcellane or China veſſels. The coarſeſt Tea is kept by the country people in ſtraw baſkets, made in the ſhape of barrels, which

[u] Lettſom, 38, &c.

they place under the roofs of their houſes, near the hole that lets out the ſmoke[x].

Thunberg adds, that the older the leaves are, and the later in the ſeaſon they are gathered, the greater is the abundance; but then the Tea is ſo much the worſe: the ſmaller leaves, and thoſe which have juſt ſhot forth, furniſh the fineſt and moſt valuable. Young ſhrubs always yield better Tea than old ones; and ſome places produce it in greater perfection and more delicious than others[y].

In the accounts of China, travellers have in general treated very ſlightly of the preparation of Tea. Le Comte obſerves, that to have good Tea, the leaves ſhould be gathered while they are ſmall, tender and juicy; that they begin commonly to gather them in march or april, according as the ſeaſon is more or leſs forward; that they afterwards expoſe them to the ſteam of boiling water to ſoften them, and as ſoon as they are penetrated by it, draw them over copper plates kept on the fire, which dries them by degrees, till they grow brown, and roll up of themſelves in the manner we receive them.

This account is in two reſpects at leaſt erroneous; for firſt, no materials are uſed in China for drying Tea but iron or earthen plates; copper is not commonly uſed in China, and from experiments, there does not appear the leaſt ſymptom of the green efflorescence of that metal having been uſed to give a verdure to the Green Teas: and ſecondly, there ſeems no probability that the leaves will of themſelves take ſo perfect a curl as that in which they are brought to Europe[z].

According to the more accurate account of Sir George Staunton; the largeſt and oldeſt leaves, which are the leaſt eſteemed, and deſtined for the uſe of the loweſt claſſes of the people, are often expoſed to ſale with little previous manipulation, and ſtill retaining that kind of vegetable taſte which is common to moſt freſh plants, but which vaniſhes in a little time, whilſt the more eſſential flavour, characteriſtic of each particular vegetable, remains long without diminution. But the young leaves undergo no inconſiderable preparation before they are delivered to the purchaſer: every leaf paſſes through the fingers of a female, who rolls it up almoſt to the form it had aſſumed before it became expanded in the progreſs of its growth. It is afterwards placed upon thin plates of earthen ware or iron, made much thinner than is executed by artiſts out of China. It is confidently ſaid in the country, that no plates of copper are ever employed for that purpoſe. Indeed, ſcarcely any utenſil uſed in China is of that metal, the chief application of which is for coin. The earthen or iron plates are placed over a charcoal fire, which draws all remaining moiſture from the leaves, rendering them dry and criſp. The colour and aſtringency of Green Tea is thought to be derived from the early period at which the leaves are plucked, and which, like unripe fruit, are generally green and acrid. For exportation, the Tea, as is well known, is packed in large cheſts lined with very thin plates of lead; and it is preſſed down into theſe cheſts by the naked feet of Chineſe labourers[a].

Chineſe drawings, though rudely executed, exhibit a faithful picture of what they are intended to repreſent. From a ſet of theſe giving the whole proceſs of gathering and manufacturing the Tea, we learn that the tree, or rather ſhrub, grows for the moſt part in hilly countries, on their rocky ſummits and ſteep declivities. Accordingly Sir George Staunton informs us, that vaſt tracts of hilly land are planted with it, particularly in the province of Fo-chen: and Chevalier Thunberg ſays, that he met with it frequently in Japan, both on the borders of cultivated lands, and upon ſuch mountains and downs as did not well anſwer the trouble of cultivation. It appears alſo from theſe drawings, that the trees in general are not much taller than a man's height: the gatherers are always repreſented on the ground; they make uſe of hooked

Digitized by Google

ſticks indeed, but theſe ſeem rather intended to draw the branches towards them, when they hang over places difficult of acceſs. They pick the leaves as ſoon as gathered into different ſorts, and cure them nearly in the manner above deſcribed to be practiſed by the Japaneſe; drying them in a range of ſtoves, like thoſe in a chemiſt's laboratory, where the men work, and curl the leaves in the pans themſelves. They dry it likewiſe, after having ſpread it abroad in ſhallow baſkets, in the ſun; and by means of ſieves, ſeparate the larger from the ſmaller leaves, and theſe again from the duſt.

The Chineſe put the finer kinds of Tea into conic veſſels, like ſugar loaves, made of tutenague, tin or lead, covering them with neat matting of bamboo. The common Tea is put into baſkets, out of which it is emptied, and packed in boxes or cheſts, as ſoon as it is ſold to the Europeans [b].

It is not known what arts are uſed in China to give a variety of colour and flavour to their Teas, which cannot all be ſatisfactorily accounted for from ſoil, ſituation, and the different ſeaſons at which the leaves are gathered. In Japan the produce is chiefly conſumed within the country; whereas in China, the exportation we know is very conſiderable, and the temptation great to exerciſe the arts of ſophiſtication, in which it is notorious the Chineſe are not deficient.

In the Chineſe drawings abovementioned, there are figures of ſeveral perſons apparently ſeparating the different kinds of Tea, and drying it in the ſun, with ſeveral baſkets ſtanding near them filled with a very white ſubſtance, and in conſiderable quantity. To what uſe this may be applied is uncertain, as well as what the ſubſtance is; yet there is little doubt that it is uſed in the manufacturing of Tea, becauſe the Chineſe do not introduce any thing into their pieces, but what relates in ſome reſpect to the ſubject.

We are better acquainted with a vegetable ſubſtance which is employed in giving a flavour to Tea. This is the Olea fragrans, the flowers of which are frequently to be met with in Teas exported from China. The plant itſelf is now not unfrequent in our ſtoves [c].

The flowers alſo of the Camellia Seſanqua and of the Arabian Jaſmin are ſometimes mixed among the Teas, for the ſame purpoſe of increaſing their fragrance. The Chineſe call the former Cha-whaw or flower of Tea. It is cultivated in vaſt abundance in China, not ſo much for this purpoſe, as for its nut, which yields an eſculent oil equal to the beſt which comes from Florence. This plant is particularly valuable from the facility of its culture on the ſides and the very tops of mountains, in ſituations fit for little elſe [d].

It ſeems probable that ſome art is uſed in dyeing Teas; they certainly give a much darker and leſs elegant infuſion than they did formerly; and the quality in general has become inferior ſince the demand has been increaſed. I remember half a century ago, that lumps of Catechu, which is an extract from a ſpecies of Mimoſa, and vulgarly called Terra japonica, were frequently found in the cheſts of Bohea Teas; and that my father, by way of experiment, dried the Green Tea that had been uſed in the family, and before it was dry ſcraped over it ſome of the Terra japonica. It curled up very well, and paſſed with the ſervants for the ſame kind of Tea that they were accuſtomed to drink. Whether lumps of that drug now come over in cheſts of Tea, or whether it is uſed by the Chineſe to colour or flavour their Teas I cannot ſay; but if they do, we have the ſatisfaction to know that it is not noxious.

We are not certain what motive induced the natives of China and Japan firſt to uſe an infuſion of Tea, but it is highly probable that it was in order to correct the water, which is ſaid to be brackiſh and ill-taſted in many parts of thoſe countries [e].

Sir George Staunton ſays, that perſons of rank in China are ſo careful about the quality of the water intended for their own conſumption, that they ſeldom

[b] Lettſom, p. 36. [c] Idem, p. 43.
[d] Staunton Embaſſy, 2. 467. [e] Lettſom, p. 19.

drink any without its being diſtilled; and every Chineſe infuſes Tea or ſome other vegetable ſuppoſed to be ſalubrious in the water which he uſes. Like beer in England, Tea is ſold in public houſes in every town; alſo by the ſide of public roads, and on the banks of rivers and canals, both in China and Japan; nor is it unuſual for the burdened and wearied traveller to lay down his load, refreſh himſelf with a cup of warm Tea, and then purſue his journey [f].

Theſe qualities, of taking off the ill taſte of water, and refreſhing after fatigue, have been experienced in other countries beſides China and Japan. Thus Kalm ſays, if Tea be uſeful, it muſt be ſo in travelling through a deſart country, where wine or other liquors cannot conveniently be carried, and where the water is generally unfit for uſe, as being full of inſects. In ſuch caſes, it is very pleaſant when boiled, and Tea is infuſed in it; nay I cannot ſufficiently deſcribe the fine taſte it has in ſuch circumſtances. It relieves a weary traveller more than can be imagined, as I have experienced with many others who have travelled through the foreſts of America: on ſuch journies Tea is found to be almoſt as neceſſary as victuals.—Forſter, the tranſlator adds, that on his own travels through the deſart plains beyond the river Volga, he has had ſeveral opportunities of making the ſame obſervations on Tea, and that every traveller in the ſame circumſtances will readily allow them to be very juſt [g].—Captain Forreſt, in his voyage to New Guinea, relates ſeveral inſtances, wherein the ſailors experienced the exhilarating effects of this infuſion [h]. Other travellers have borne teſtimony to this pleaſant and ſalutary effect of Tea. And perſons, after violent exerciſe, or coming off a journey much fatigued, and affected with a ſenſe of general uneaſineſs, attended with thirſt and great heat, by drinking a few cups of warm Tea, commonly experience immediate refreſhment. It alſo proves a grateful diluent, and agreeable ſedative, after a full meal, when the ſtomach is oppreſſed, the head pained, and the pulſe beats high [i]. The warm infuſion of any aromatic herb, is likely to be grateful to perſons exhauſted with fatigue, and to ſtomachs labouring with indigeſtion [k].

Neither the Chineſe, nor the natives of Japan, ever uſe Tea, before it has been kept at leaſt a year; becauſe when freſh it is ſaid to prove narcotic, and to diſorder the ſenſes. The Chineſe pour hot water on the Tea, and draw off the infuſion in the ſame manner as is now practiſed in Europe; but they drink it without ſugar or milk. The Japaneſe reduce the Tea to a fine powder, by grinding the leaves in a hand-mill; the cups are filled with hot water, and as much of this powder as might lie on the point of a moderate-ſized knife is put into each cup, and ſtirred about till the liquor foams, and it is ſipped while warm. According to Du Halde, this method is alſo uſed in ſome provinces of China.

The common people, who have a coarſer Tea, boil it for ſome time in water, and uſe the liquor for common drink. Early in the morning, the kettle filled with water, is hung over the fire, and the Tea is either put in incloſed in a bag, or by means of a baſket preſſed to the bottom of the veſſel. The coarſeſt Tea only is uſed in this manner, the qualities of which being more fixed, would probably not be ſo fully extracted by infuſion.

Tea indeed is the common beverage of all the labouring people in China; and they are ſcarcely ever repreſented at work of any kind, but the Tea-pot and Tea-cup appear as their accompaniments: reapers, threſhers, and all who work out of doors, as well as within, have theſe attendants [l].

With reſpect to the qualities of Tea, it appears, that an infuſion of Green Tea has the effect of deſtroying the ſenſibility of the nerves, and the irritability of the muſcles; and that it gives out in diſtillation an odorous water, which is powerfully narcotic.

That the recent plant contains ſuch an odorous narcotic power, we might preſume from the neceſſity which the Chineſe find of drying it with much heat before it can be brought into uſe; and that even after ſuch preparation, they muſt abſtain from the uſe of it for a year or more, that is, till its volatile parts are ſtill farther diſſipated: and it is ſaid, that unleſs they uſe this precaution, the Tea in a more recent ſtate manifeſtly ſhows ſtrong narcotic powers. Even in this country, the more odorous Teas often ſhow their ſedative powers in weakening the nerves of the ſtomach, and indeed of the whole ſyſtem.

From theſe conſiderations it may fairly be concluded, that Tea is to be conſidered as a narcotic and ſedative ſubſtance; and that it is eſpecially ſuch in its moſt odorous ſtate, and therefore leſs in the Bohea than in the Green Tea, and the moſt ſo in the finer kinds of the latter.

Its effects however ſeem to be very different in different perſons; and hence the contradictory accounts that are given of them. But if we conſider the difference of conſtitution, which occaſions ſome variation in the operating of the ſame medicine, and of which we have a remarkable proof in the operation of Opium, we ſhall not be ſurpriſed at the different operations of Tea.

If to this we add the fallacy ariſing from the condition of the Tea employed, which is often ſo inert as to have little or no effect; and if we ſtill add to this the power of habit, which can deſtroy the efficacy of the moſt powerful ſubſtances, we ſhall not allow the various and even contradictory reports of its effects to alter our judgment, with reſpect to its ordinary and more general qualities in affecting the human body.

Theſe, from experiments and obſervations, are clearly narcotic and ſedative.

It is not at the ſame time to be denied, that Tea may ſometimes have good effects. It is very poſſible, that in certain perſons, taken in moderate quantities, it may, like other narcotics, prove exhilarating, or like them, have ſome effect in taking off irritability, or in quieting ſome irregularities of the nervous ſyſtem.

As its bad effects have been often imputed to the warm water that accompanies the Tea, ſo there is no doubt that ſome of its good effects may alſo be aſcribed to the ſame cauſe, and particularly its being ſo often grateful after a full meal[m].

After all, the infuſion of Tea, as it is commonly taken in England, with a competent quantity of cream or milk and ſugar, cannot be very narcotic or ſedative: eſpecially as after a long voyage it is kept ſome time in the Eaſt India Company's warehouſes; and the finer ſorts of it are not ſo much in requeſt as formerly. Nor can it be an unwholeſome beverage for ſedentary perſons and ſuch as live freely, provided it be not taken too hot, or in immoderate quantities, or without any ſolid food accompanying it. For the lower claſs of people who generally live poorly, and procure little animal food, Tea conveying little or no nouriſhment, is a bad ſuccedaneum for beer; and a meal on it, including ſugar and butter, is ſo expenſive, that they muſt forego what is more neceſſary for their ſupport, in order to enjoy it.

When the Chineſe firſt began to make uſe of Tea as a beverage we are not able to ſay, but it is probable that the ill taſte of the water in many parts of the empire would induce them to look out for ſome vegetable to correct it, ſoon after they arrived at a ſtate of civilization. The firſt account that we have of it is from two Arabian travellers, who viſited China about the year 850, and relate that the inhabitants of that empire had a medicinal beverage, named Chah or Sah, which was prepared by pouring boiling water on the dried leaves of a certain herb, which infuſion was reckoned an efficacious remedy in various diſeaſes[n]. From the great revenue which theſe travellers inform us was levied from the conſumption of Tea, it ſeems then to have been as univerſally the favourite beverage of the Chineſe in the ninth century, as it is at preſent[o].

Giovanni Botaro, an eminent Italian author obſerves, that the Chineſe have an herb, out of which they preſs a delicate juice, which ſerves them for a drink inſtead of wine: it alſo preſerves their health, and frees them from all thoſe evils that the immoderate uſe of wine doth breed in us[p].

About the year 1600, Texeira, a Spaniard, ſaw the dried leaves in Malacca, where he was informed that the Chineſe prepared a drink from this vegetable: and in 1633, Olearius found this practice prevalent among the Perſians, who procured the plant under the name of Cha orchia, from China, by means of the Uſbeck Tartars. In 1639, Stirkaw, the Ruſſian Ambaſſador at the court of the Mogul Chau Altyn, partook of the infuſion of Tea; and at his departure was offered a quantity of it, as a preſent for the Czar Michael Romanoff, which the Ambaſſador refuſed, as being an article for which they had no uſe in Ruſſia[q].

Tea was not known in Europe as a beverage, before the commencement of the ſeventeenth century. Some Dutch adventurers ſeeking, about that time, for ſuch objects as might fetch a price in China, and hearing of the general uſage there of a beverage from a plant of the country, bethought themſelves of trying how far an European plant, of ſuppoſed great virtues, might alſo be reliſhed by the Chineſe, and thereby become a ſaleable commodity amongſt them; and accordingly introduced to them the herb *Sage*, ſo much once extolled by the Salernian ſchool of phyſic, as a powerful preſervative of health: the Dutch accepting in return the Chineſe Tea, which they brought to Europe. The European herb did not continue, long at leaſt, in uſe in China; but the conſumption of Tea has been gradually increaſing in Europe ever ſince[r].

What authority Sir George Staunton had for the particulars of the above account, I do not know, but it is certain that Tea was introduced into Europe by the Dutch Eaſt India Company, very early in the ſeventeeth century. Dr. Lettſom thinks it probable that the Dutch, as they traded conſiderably to Japan about that time, might have brought this article firſt from thence. But China ſoon became the general mart, and the province Fokien or Fo-chen is the principal country, that ſupplies both the Empire and Europe with this commodity. In this province, the ſhrub is called Thee or Te; and the Europeans having firſt landed there, that dialect has been preſerved[s].

I have been informed that Sage was much eſteemed in China; and I recollect that Mr. Miller had a preſent of a parcel of Tea from that country, which on being infuſed, had ſo much the flavour of Sage, that he ſent for ſome of the broad-leaved Sage out of the garden, and having made an infuſion of that, he and my father could ſcarcely diſtinguiſh them. It is certain however that the European has not made its fortune in China, as the Chineſe ſhrub has done here.

The firſt introduction of Tea into England was before the year 1660, when the firſt mention of it was made in the ſtatute book, and a duty of four-pence a gallon laid on the liquor made and ſold in all coffee-houſes.

A quantity of it being brought over from Holland about the year 1666 by Lord Arlington and Lord Oſſory, Tea ſoon came into requeſt among people of faſhion, and its uſe, by degrees, ſince that period, has become general[t]. Hanway informs us, that at this time it ſold for ſixty ſhillings a pound[u].

From theſe ſmall beginnings, we have ſeen the infuſion of a leaf from almoſt the fartheſt extremity of the earth become in a manner a neceſſary of life, in ſeveral parts of Europe, and the paſſion for it deſcend from the moſt elevated to the loweſt orders in ſociety. In 1785 it was computed that the whole quantity of Tea imported into Europe was about nineteen mil-

lions of pounds, of which it is conjectured that twelve millions were conſumed in Great Britain and its dependencies [u].

Sir George Staunton informs us, that the annual public ſales of Teas, by our Eaſt India Company, did not, in the beginning of the eighteenth century, much exceed fifty thouſand pounds weight, independently of what little might be then perhaps clandeſtinely imported. The Company's annual ſales now (about 1797) approach to twenty millions of pounds; being an increaſe of four hundred fold, in leſs than one hundred years, and anſwers to the rate of more than a pound each, in the courſe of the year, for the individuals of all ranks, ſexes and ages, throughout the Britiſh dominions in Europe and America [x].

Since the year 1797, it is probable, that the importation of Tea has much increaſed, and that at leaſt thirty millions of pounds are annually imported into Europe and America [y].

Taking an average of ſeven years before the Commutation Act, which took effect in ſeptember 1784, the importation of Teas was 17,662,115 lb; and taking an average of the ſame number of years from 1784 incluſive, it amounted to 30,691,971 lb.

Curioſity and intereſt would induce the Europeans to diſcover the real Tea ſhrub, and the jealous caution of the Chineſe would make them uſe every endeavour to conceal it. Simon Paulli a celebrated phyſician and botaniſt at Copenhagen, was the firſt who pretended to have diſcovered the genuine Tea plant, in the Myrica Gale, an inhabitant of England, Brabant, and other northern countries of Europe, and known to us by the names of Sweet Gale, Goule or Gaule, Sweet Willow, Wild or Dutch Myrtle. Father Labat thought that he had diſcovered it in Martinico. He pretended alſo to have procured Tea ſeeds from the Eaſt Indies, and to have raiſed the plant in America; but from his own account it appears to be a ſpecies of Lyſimachia, or what is called Weſt-India Tea.

Many other pretended diſcoveries of the Chineſe Tea-tree have been related; all which have proved erroneous, when properly enquired into. Camellia Saſanqua has the neareſt reſemblance to it [z]. Linneus ſays it is ſo great, that it might deceive a ſkilful botaniſt; the only difference being, that thoſe of the Camellia are a little broader. Thunberg ſays, that the leaves of the true Tea-tree are thicker and recurved; that the flowers are axillary and two together, the petals ſmaller and not keeled under the tip. But theſe two plants cannot be confounded when they are in flower. It is reported that the leaves of the Camellia are mixed with Tea, to give it a fine flavour. This beautiful plant has been repeatedly ſent to Europe inſtead of the true Tea. Linneus endeavoured for many years to procure the Tea-tree for the botanic garden at Upſal; but by a variety of accidents, they were all deſtroyed on the paſſage. At length, about the year 1755, Mr. Lagerſtroem, a director of the Swediſh Eaſt India Company, brought him two plants alive, which he had bought in China; but they proved to be the Camellia, the crafty Chineſe having taken care to pull off the flowers. In 1769 Linneus received a branch from France, which was brought from China for the true Tea, but that proved alſo to be the Camellia [a]; which is now not uncommon in our Engliſh greenhouſes. Before the true Tea-tree was introduced, this or ſome other ſhrub was generally ſhewn for it; and ſometimes plants that bore no reſemblance to it were endeavoured to be obtruded upon the curious but ignorant enquirer.

PROPAGATION AND CULTURE.

In Japan the Tea-tree is cultivated round the borders of rice and corn-fields, without any regard to the ſoil. Seeds contained in the ſeed-veſſels, from ſix to twelve or fifteen, are put into one hole, four or five inches deep. The ſeeds contain a large proportion of oil, which is liable ſoon to turn rancid; hence

[u] Robertſon's India, p. 252.
[x] Embaſſy, 1. 22.
[y] Lettſom, p. 101.
[z] Idem, p. 40.
[a] Ellis, p. 28.

ſcarcely a fifth part of them germinate, and this makes it neceſſary to plant ſo many together. The ſeeds vegetate without any farther care: but the more induſtrious annually remove the weeds, and manure the land.

The leaves are not fit to be plucked before the third year's growth. In ſeven years the tree is uſually cut down, and abundance of freſh ſhoots ſpring up. Some defer cutting it till it is of ten years growth [b].

In China, wherever it is regularly cultivated, it riſes from the ſeed ſown in rows, at the diſtance of about four feet from each other, in land kept free from weeds. It is ſeldom ſown on flat or marſhy ground, which is reſerved for rice, but vaſt tracts of hilly land are planted with it, particularly in the province of Fo-chen. Its perpendicular growth is impeded for the convenience of collecting the leaves. Its long and tender branches ſpring up almoſt from the root, without any intervening naked trunk.

The Tea-tree is cultivated in ſeveral of the provinces of China, but ſeldom more northerly than thirty degrees beyond the equator. It thrives beſt between that parallel and the line that ſeparates the temperate from the torrid zone; though it is to be found alſo in the province of Yunnan, to the ſouthward of it [c].

The ſouthern countries of Europe, and ſome provinces of North America would ſuit it, particularly the latter, the heat there in ſummer being ſuch, that vegetables make quicker and more early ſhoots, and therefore acquire more ſtrength and firmneſs before the winter commences.

To propagate the Tea-tree in Europe it is neceſſary to procure ſeeds from China. Care muſt be taken that they be freſh, ſound, ripe, white, plump and moiſt internally. After being well dried in the ſun, they may be incloſed in bees-wax: or, left in their capſules, they may be put into very cloſe caniſters of tin or tutenague. Thouin, in his directions to Peroufe, recommends theſe and other ſeeds to be placed in alternate layers of earth or ſand, in tin boxes, cloſed up exactly, and placed in ſolid caſes, covered with waxed cloth; the boxes to be placed in a part of the ſhip the leaſt acceſſible to moiſture, and the moſt ſheltered from extreme heat or cold. Mr. Sneyd was very ſucceſsful in having ſeeds packed up in abſorbent paper, and ſurrounded by raiſins or moiſt ſugar, which kept them in a ſtate fit for vegetation. American ſeeds are frequently brought over, by putting them into a box, not made too cloſe, upon alternate layers of moſs, in ſuch a manner as to admit the ſeeds to vegetate. This might be tried with the ſeeds of the Tea-tree: and to ſucceed more certainly, ſome of the ſeeds might be ſown in pots or boxes, when the veſſel arrives at St. Helena, and after paſſing the tropic of Cancer, near the latitude of thirty degrees north.

But the beſt method ſeems to be, to ſow ripe ſeeds in good light earth in boxes, at leaving Canton; covering them with wire, to prevent rats and other vermin from coming to them; and taking care that the boxes be not expoſed to too much air, nor to the ſpray of the ſea. A little freſh or rain water ſhould be ſprinkled over them now and then; and when the ſeedling plants appear, they ſhould be kept moiſt, and out of the burning ſun. If young plants can be procured in China, they may be ſent over in a growing ſtate in boxes, forty inches long, by twenty broad, and as much in depth, having a few holes bored through the bottom.

When the trees arrive in England, they muſt be kept in a green-houſe during the winter, and in the open air during the ſummer. If they come in bad condition, it may not be amiſs to plunge the pots into which they are tranſplanted, in a gentle hot-bed, or to ſet them in the tan-pit, to make them ſtrike and ſhoot more freely.

Though the Tea-tree will not at preſent bear the rigour of our winters, in the open air, yet it is not impoſſible but it may gradually become naturalized to

[b] Kæmpfer. Lettſom, p. 26.

our climate, like the Magnolia, among ſeveral other trees and ſhrubs; eſpecially if it were to be brought from the coldeſt provinces of China where it grows, or from the parts of Europe a little to the ſouthward of us, when it ſhall have been naturalized there[d].

The Tea-tree may be increaſed freely from cuttings, in the ſame manner with Gardenia: and it will alſo probably grow from layers.

DESCRIPTION, *&c.*

It is an annual plant, which decays as ſoon as the ſeeds are ripe. The ſtalks trail on the ground like thoſe of Chickweed; they grow about a foot long, their joints are pretty cloſe, and have ovate acute-pointed leaves, on pretty long bordered foot-ſtalks. One of theſe leaves is placed at each joint, and from the ſame point come out ſeveral ſmaller leaves of the ſame ſhape, on ſhorter footſtalks. Flowers axillary in cluſters ſitting very cloſe, ſmall, and of an herbaceous white colour, male and female from the ſame joint.

[Stems round, diffuſed, flexuoſe, ſucculent. Branches oppoſite, divaricate, from the axils of the oppoſite leaves. Leaves ovate, bluntiſh, even, nerved, ſlightly marked with lines, oleraceous, rugged at the edge; the lower ones oppoſite, the upper alternate, ending in the petioles, which are the length of the leaves, and connected on each ſide by a three-toothed, membranaceous, wide, ſhort ſtipule. Male flowers two together, oppoſite to a leaf, on very ſhort one-flowered peduncles: anthers from thirteen to nineteen, linear. Female flowers ſolitary, ſeſſile, axillary[e].

Gærtner conſiders the pericarp as a ſmall ſuperior nut, of an ovate-globular form, coriaceous, of a blackiſh-brown colour, lengthened out at the baſe into a ſhort hollow proceſs; one-celled, valveleſs. Seed one, globular, pale, faſtened to the bottom of the nut by a ſmall umbilical tubercle at its baſe.

Native of the South of France, near Montpelier, Italy in the iſland of Caprea, county of Nice, &c. and Sicily. Said by Linneus to be common in the Eaſt Indies. Found by Desfontaines in the kingdom of Tunis, on mount Zowan. Mr. Miller adds Tartary. It was cultivated by him in 1759[f].]

PROPAGATION AND CULTURE.

Sow the ſeeds in autumn, where the plants are to remain, for when ſown in the ſpring, the plants rarely come up the ſame year. They require no culture but to be kept clean from weeds, and to be thinned where they are too cloſe.

DESCRIPTION, *&c.*

[The Cacao or Chocolate-nut tree grows in a very handſome form, to the height of twelve or ſixteen feet: the trunk is upright and about as high as a man before the head ſpreads out: the wood is light and of a white colour, and the bark is browniſh and even. Leaves lanceolate-oblong, bright green, quite entire, alternate, from nine to ſixteen inches long, and three or four inches wide at moſt, on a petiole an inch in length and thickened at both ends. Peduncles ſlender, about eight or ten together, chiefly from the ſcars of the fallen leaves; one of them only for the moſt part fruitful, the reſt abortive. Flowers ſmall, reddiſh, inodorous. Fruits ſmooth, yellow, red, or of both colours, about three inches in diameter: rind fleſhy, near half an inch in thickneſs, fleſh-coloured within: pulp whitiſh, the conſiſtence of butter, ſeparating from the rind in a ſtate of ripeneſs, and adhering to it

[d] Lettſom, p. 54 to 58.

Digitized by Google

only by filaments, which penetrate it and reach to the ſeeds. Hence it is known when the ſeeds are ripe, by the rattling of the capſule when it is ſhaken. The pulp has a ſweet and not unpleaſant taſte, with a ſlight acidity; it is ſucked and eaten raw by the natives: it may be eaſily ſeparated into as many parts as there are ſeeds, to which it adheres ſtrongly, and they are wrapped up in it, ſo that each ſeed ſeems to have its own proper pulp. The ſeeds are about twenty-five in number: when freſh they are of a fleſh-colour: gathered before they are ripe, they preſerve them in ſugar, and thus they are very grateful to the palate: they quickly loſe their power of vegetation, if taken out of the capſule, but kept in it, they preſerve that power for a long time. The tree bears leaves, flowers and fruit all the year through; but the uſual ſeaſons for gathering the fruit are june and december. In two years from the ſeed it is above three feet high, and ſpreads its branches, not more than five of which are ſuffered to remain: before its third year is complete it ſhows for fruit. A tree yields from two to three pounds of ſeeds annually.

It is thus deſcribed by Dampier. The Cacao tree has a body about a foot and half thick, and ſeven or eight feet high to the branches, which are large and ſpreading, with a pretty thick, ſmooth, dark-green leaf, ſhaped like that of a Plum-tree, but larger. The nuts are incloſed in cods as big as both a man's fiſts put together: at the broad end is a ſmall, tough, limber ſtalk, by which they hang pendulous from the body of the tree, in all parts of it from top to bottom, ſcattered at irregular diſtances, and from the great branches a little way up; eſpecially at the joints or partings, where they hang thickeſt; but never on the ſmaller boughs. There may be ordinarily twenty or thirty of theſe cods upon a well-bearing tree; and they have two crops of them in a year, one in december, but the beſt in june. The ſhell is almoſt half an inch thick, brittle, yet harder than the rind of a lemon; like that, its ſurface is grained or knobbed, but more coarſe and unequal. The cods at firſt are of a dark green, but the ſide next the ſun of a muddy red. As they grow ripe, the green turns to a fine bright yellow, and the muddy to a more lively red. They do not ripen all at once, but for three weeks or a month in the ſeaſon, the overſeers of the plantations go every day to cut thoſe which are turned yellow. They lay them in heaps to ſweat, and then burſting the ſhell with their hands, they pull out the nuts, of which there are generally near a hundred in a cod; drying them in the ſun upon mats.

According to Browne, the Cacao or Chocolate tree ſeldom exceeds ſix or ſeven inches in diameter, or riſes above fifteen or ſixteen feet in height. It is very beautiful, and in general extremely engaging to the ſight, when charged with fruit, which grows from all parts of the trunk and larger branches indiſcriminately. When the ſeeds are looſe and rattle in the pods, they are picked off, opened, and the kernels picked out and expoſed daily to the ſun, until they are thoroughly cured, and fit for the ſtore or market.

Theſe ſeeds are remarkably nouriſhing, and agreeable to moſt people; which occaſions them to be commonly kept in moſt houſes in America, as a neceſſary part of the proviſions of the family: they are generally ground or pounded very fine, and made into paſte: they are much charged with oil, but mix well with milk or water. Chocolate is much eſteemed in all the ſouthern colonies of America; and well known to make the principal part of the nouriſhment of moſt old people in thoſe parts, as well as of a great number of Jews.—It was in uſe among the native Indians, before the arrival of the Spaniards.]

Native of South America, and found in great plenty in ſeveral places between the tropics, but particularly at Caracca and Carthagena, on the river Amazons, the iſthmus of Darien, at Honduras, Guatimala and Nicaragua.

[Dampier ſays that the Cacao tree grows no where in the north ſeas but in the bay of Campeachy, on Coſta Rica, between Portabel and Nicaragua, chiefly up Carpenter's river, and on this coaſt as high as the iſland of Trinidada. In the South Seas it grows by the river of Guiaquil, and in the valley of Collima, on the ſouth ſide of Mexico. The nuts of the coaſt of Caraccos, though leſs than thoſe of Coſta Rica, which are large and flat, are better and fatter. —In many places the nuts went for current money before the arrival of the Spaniards; and ſince that, tribute has been paid them in ſome provinces, in Chocolate nuts.]

This tree is cultivated in many of the Weſt India iſlands, belonging to the French and Spaniards, and formerly in ſome of thoſe belonging to the Engliſh; but it has been ſo neglected in the latter for many years paſt, that we are now ſupplied with Chocolate from the French and Spaniards. [The reaſon probably has been, the difficulty of raiſing the young trees, and their unfitneſs to reſiſt the force of thoſe hurricanes, to which the Weſt India iſlands are ſubject.

Blome, who publiſhed a ſhort account of Jamaica in 1672, ſpeaks of Cacao as being at that time one of the chief articles of exportation: "there are, ſays he, in the iſland at this time, about ſixty Cacao walks, and many more now planting."

At preſent (ſays Edwards, 2. 306.) I believe there is not a ſingle Cacao plantation from one end of Jamaica to the other. A few ſcattered trees here and there are all that remain of thoſe flouriſhing and beautiful groves which were once the pride and boaſt of the country.

There is reaſon to apprehend that our ſugar iſlands can never again enter into competition with the Spaniſh Americans in the cultivation of Cacao. At preſent the only plantations of any account, in our colonies, are in Grenada and Dominica, and the export from them cannot be eſtimated at more than four thouſand bags of a hundred weight each [h].

Browne ſays that Chocolate trees are often found wild in the woods of Jamaica, where doubtleſs they had been cultivated in the time of the Spaniards. The trees are very delicate, and rarely ſurvive, when once they are looſened in the ground, which is generally the caſe, when they are not well ſheltered, in hurricane times. The Spaniards, to prevent this, uſed to intermix many of the Erythrina or Coral Bean trees, hence called Mader di Cacao, in their walks. Many however thrive well, without any ſhelter of this kind, but probably they were protected while young, and they have been generally planted in a good deep mould, and a warm ſheltered ſituation.

Jacquin informs us, that ſince the great hurricane in 1725, which deſtroyed the Cacao trees in Martinico and the neighbouring iſlands, they have been ſo little cultivated as ſcarcely to ſupply the home conſumption. He thinks that the culture of Coffee, which is more certain, has contributed much to this neglect. A young plant of that ſhrub was firſt introdubed into Martinico by De Clieux, a captain in the French infantry, in the year 1720, from the royal garden at Paris; and it increaſed ſo much, that in 1756, when Jacquin was there, one hundred and eighty hundred thouſand pounds were exported to Europe from that iſland alone.

The Chocolate-nut tree was cultivated by Mr. Miller in 1739 [i].

There are two principal varieties of the fruit; one long, of an oval-oblong form, obtuſely attenuated at the end, ten-grooved, and having the ſurface irregular with little bumps, or ſomewhat warted, as it is figured by Cateſby; this is called in Martinico *Cacao du pays*: the other ovate, not at all warted, ſcarcely grooved, as thick as the other but ſhorter; this is called *Cacao de Cayenne*, being ſuppoſed to come from that country. The latter was introduced into Martinico after the hurricane [k]. Both are frequent wild in Jamaica [l].]

PROPAGATION AND CULTURE.

As the Chocolate-nut tree may be cultivated to advantage in the Weſt India iſlands, where Sugar-

canes do not thrive, I ſhall therefore ſubjoin the beſt account of the culture which it requires in thoſe countries, with the profits which have ariſen from it to thoſe who have planted ſome of theſe trees of late years, by way of experiment, in order to excite others to follow their example; and ſhall afterwards give directions for cultivating it in England, by way of curioſity.

In making a plantation of Chocolate-trees, you muſt firſt be very careful in the choice of the ſituation, and the ſoil, otherwiſe there will be ſmall hopes of ſucceſs. As to the ſituation, it ſhould be in a place where the trees may be protected from ſtrong winds, to which if they are expoſed, they will ſoon be deſtroyed: ſo that in ſuch places where torrents of water have waſhed away the earth ſo as to leave broad and deep furrows (which the inhabitants of thoſe iſlands call gullies,) theſe trees will thrive exceedingly: and as theſe are very frequently to be found in thoſe iſlands, and many of them are of large extent, and not much cultivated, it may be a great improvement to ſome eſtates, which, at preſent, are of ſmall value. The ſoil in theſe gullies is generally rich and moiſt, which is what theſe trees require; ſo that they will make great progreſs in theſe places, as hath been experienced by thoſe perſons, who have lately made trials of the plants in theſe ſituations; but where there are not a ſufficient number of theſe gullies, choice ſhould be made of a ſituation which is well ſheltered by large trees; or, if there are not trees already grown, there ſhould be three or four rows planted round the ſpot which is deſigned for the Chocolate-trees, of ſuch ſorts which are of quickeſt growth; and within theſe rows there ſhould be ſome Plantain-trees, planted at proper diſtances, which being very quick of growth, and the leaves very large, will afford a kindly ſhelter to the young Chocolate-trees placed between them.

The Chocolate-trees which are cultivated, ſeldom grow to more than fourteen or fifteen feet in height, nor do they ſpread their branches very wide; ſo that if the Plantain-trees are placed in rows, about twenty-four feet aſunder, there will be room enough for two rows of Chocolate-trees between each row of Plantains; and if they are placed at ten feet diſtance in the rows, it will be ſufficient room for them. Thoſe trees which are found wild in uncultivated places, are generally of much larger growth, which may be occaſioned by the other trees, amongſt which theſe are found growing; for, being protected from the winds by thoſe, they are not ſo much in danger therefrom, as thoſe which are cultivated: and the other trees cloſely ſurrounding them, will naturally draw them up to a greater height: however, that is not a deſirable quality in theſe trees; for the lower they are, the better the fruit may be gathered without hurting the trees, and the leſs they are expoſed to the injuries of the weather; ſo that the inhabitants never deſire to have their trees above twelve or fourteen feet high.

The ſoil upon which theſe trees thrive to moſt advantage, is a moiſt, rich, deep earth; for they generally ſend forth one tap root, which runs very deep into the ground, ſo that wherever they meet with a rocky bottom near the ſurface, they ſeldom thrive, nor are they of long continuance; but in a rich, deep, moiſt ſoil, they will produce fruit in pretty good plenty the third year from ſeed, and will continue fruitful for ſeveral years after.

Before the plantation is begun, the ground ſhould be well prepared by digging it deep, and clearing it from the roots of the trees, and noxious plants, which, if ſuffered to remain in the ground, will ſhoot up again after the firſt rain, and greatly obſtruct the growth of the plants; ſo that it will be almoſt impoſſible to clear the ground from thoſe roots, after the Chocolate plants are come up, without greatly injuring them.

When the ground is thus prepared, the rows ſhould be marked out by a line, where the nuts are to be planted, ſo as that they may be placed in a quincunx order, at equal diſtance every way, or at leaſt that

the Plantain-trees between them may form a quincunx, with the two rows of Chocolate-trees, which are placed between each row of them.

In making a plantation of Chocolate-nut-trees, the nuts muſt be planted where the trees are to remain; for if the plants are tranſplanted, they ſeldom live; and thoſe which ſurvive it, will never make thriving trees; for, as I before obſerved, theſe trees have a tender tap root, which, if broke, or any way injured, the tree commonly decays.

The nuts ſhould always be planted in a rainy ſeaſon, or at leaſt when it is cloudy weather, and ſome hopes of rain falling ſoon after. As the fruit ripens at two different ſeaſons, viz. at Midſummer and at Chriſtmas, the plantation may be made at either of thoſe; but the chief care muſt be to chooſe ſuch nuts as are perfectly ripe and ſound, otherwiſe the whole trouble and expence will be loſt. The manner of planting the nuts is, to make three holes in the ground, within two or three inches of each other, at the place where every tree is to ſtand; and into each of theſe holes ſhould be one ſound nut planted about two inches deep, covering them gently with earth. The reaſon for putting in three nuts at every place is, becauſe they ſeldom all ſucceed; or, if moſt of them grow, the plants will not be all equally vigorous; ſo that when the plants have had one year's growth, it is very eaſy to draw up all the weak unpromiſing plants, and leave the moſt vigorous; but in doing this, great care ſhould be had of the remaining plants, ſo as not to injure or diſturb their roots in drawing the others out.

It is very proper to obſerve, that the Chocolate-nuts will not retain their growing faculty long after they are taken from the trees, ſo that there is no poſſibility of tranſporting them to any great diſtance for planting; nor ſhould they be kept long out of the ground, in the natural places of their growth. There are ſome authors, who have written the hiſtory of this tree, and diſtinguiſh three different ſorts of the nuts, from the colour of their ſkins, one of which is of a whitiſh green colour, one of a deep red, and the third of a red and yellow colour; but theſe are not ſpecifically different, but all ariſe from ſeeds of the ſame tree, as is the caſe of our Filberts, which differ in the colour of their ſkins, but are of the ſame colour within, and have the ſame taſte. There are others, who would diſtinguiſh theſe nuts by their ſize and form, ſome being large and thick, others almoſt as flat as Beans; but theſe differences, I have been credibly informed, ariſe from ſome accident, as thoſe trees which are young and vigorous, and grow upon a deep rich ſoil will always produce larger and better nouriſhed fruit, than thoſe which ſtand on a ſhallow dry ground, and are unthriving trees: as will alſo the age of a tree make a great alteration in the ſize of the fruit; for old trees are generally obſerved to produce ſmaller and flatter nuts than thoſe which are young, or than the ſame trees did bear while they were vigorous.

When the Chocolate-trees firſt appear above ground, they are very tender, and ſubject to great injuries from the ſtrong winds, the ſcorching ſun, or great droughts, for which reaſon the planters are obliged to guard againſt all theſe enemies, firſt, by making choice of a ſheltered ſituation, or at leaſt by planting trees to form a ſhelter; and, if poſſible, to have the plantation near a river, for the conveniency of watering the plants the firſt ſeaſon, until they have made ſtrong roots, and are capable of drawing their nouriſhment from ſome depth in the earth, where they meet with moiſture. But in order to ſhelter the plants from the ſcorching rays of the ſun, they generally plant two rows of Caſſada between each row of Chocolate-trees, which will grow about ſeven or eight feet high, and ſcreen the young plants from the violence of the ſun the firſt ſeaſon; after which time, they will be in leſs danger of injury therefrom; and the following ſeaſon, when the Caſſada is taken up for uſe, the ground ſhould be worked between the young plants, being very careful not to injure their roots by this operation. This method of plant-

ing

Digitized by Google

ing the Caſſada between the young Chocolate-trees, is of great advantage to the planter; for when the roots of the Caſſada are taken up for uſe, it will defray the expence of keeping the ground clean from weeds, without which the young plants will come to nothing. The Plantains alſo, which will be fit to cut in about twelve months after planting, will defray the whole expence of preparing the ground, ſo that the produce of the Chocolate-trees will be neat profit; for as the Plantains produce fruit and decay, they will be ſucceeded by ſuckers, which will produce fruit in eight months after; whereby there will be a continual ſupply of food for the negroes, which will more than pay for keeping the ground wrought, and clear from weeds, until the Chocolate-trees begin to produce fruit, which is generally the third year after planting.

The planters uſually ſet the Plantain-trees two or three months before the Chocolate-nuts are ripe, that they may be large enough to afford ſhelter to the young plants when they come up; and the Caſſada is always planted a month or ſix weeks before the Chocolate-nuts, for the ſame reaſon. Some people plant Potatoes, others Cucumbers and Melons, or Water Melons, between the rows of Chocolate plants; which, they ſay, will prevent the weeds from riſing to injure the young plants: for as all theſe trail on the ground, they occupy the whole ſurface, and prevent the weeds from growing: but where this is practiſed, it ſhould be done with great caution, leſt, by being over-covetous, you injure the young Chocolate-nuts ſo much, that they may never recover it; therefore great care ſhould be taken to reduce the ſhoots of theſe plants, whenever they approach the Chocolate-trees; otherwiſe they will ſoon greatly injure, if not totally deſtroy them.

In about ſeven or eight days after the Chocolate-nuts are planted, the young plants will begin to appear above ground; when they ſhould be carefully looked over, to ſee if any of them are attacked by inſects; in which caſe, if the inſects are not timely deſtroyed, they will ſoon devour all the young plants; or if there ſhould be any weeds produced near the plants, they ſhould be carefully cut down with a hoe; in doing which, great care ſhould be taken that neither the tender ſhoot, nor the rind of the bark are injured.

About twenty days after the plants have appeared, they will be five or ſix inches high, and have four or ſix leaves, according to the ſtrength of the plants. Theſe leaves are always produced by pairs, oppoſite to each other, as are alſo the branches; ſo that they make very regular handſome heads, if they are not injured by winds. In ten or twelve months they will be two feet and a half high, and have fourteen or ſixteen leaves. By this time the Caſſada, which was planted between the rows of Chocolate plants, will have large roots fit for uſe, therefore ſhould be taken up; and the ground being then wrought over again, will greatly encourage the young plants.

In two years time the plants will have grown to the height of three feet and a half, or ſometimes four feet, many of which will begin to flower; but the careful planters always pull off all theſe bloſſoms; for if they are permitted to remain to produce fruit, they will ſo much weaken the trees, that they ſeldom recover their ſtrength again, ſo as to become vigorous. When theſe plants are two years and a half old, they will produce flowers again, ſome of which are often left to bear fruit; but the moſt curious planters pull off all theſe, and never leave any to produce fruit until the third year; and then but a few, in proportion to the ſtrength of the trees; by which method, their trees always produce larger and better nouriſhed fruit, than thoſe which are ſuffered to bear a larger quantity, and will continue much longer in vigour. The fourth year they ſuffer their trees to bear a moderate crop, but they generally pull off ſome flowers from thoſe trees which are weak, that they may recover ſtrength before they are too old.

From the time when the flowers fall off, to the maturity of the fruit, is about four months. It is eaſy to know when the fruit is ripe by the colour of the

pods, which become yellow on the ſide next the ſun. In gathering the fruit, they generally place a negro to each row of trees; who, being furniſhed with a baſket, goes from tree to tree, and cuts off all thoſe which are ripe, leaving the others for a longer time to ripen. When the baſket is full, he carries the fruit, and lays it in a heap at one end of the plantation; where, after they have gathered the whole plantation, they cut the pods lengthways, and take out all the nuts, being careful to diveſt them of the pulp which cloſely adheres to them; and then they carry them to the houſe, where they lay them in large caſks, or other veſſels of wood, raiſed above ground, and cover them with leaves of the Indian Reed and mats, upon which they lay ſome boards, putting ſome ſtones thereon to keep them down cloſe, in order to preſs the nuts. In theſe veſſels the nuts are kept four or five days; during which time, they muſt be ſtirred and turned every morning; otherwiſe they will be in danger of periſhing from the great fermentation they are uſually in. In this time they change from being white to a dark red or brown colour. Without this fermentation, they ſay the nuts will not keep; but will ſprout, if they are in a damp place, or ſhrivel and dry too much, if they are expoſed to heat.

After the nuts have been thus fermented, they ſhould be taken out of the veſſels and ſpread on coarſe cloths, where they may be expoſed to the ſun and wind; but at night, or in rainy weather, they muſt be taken under ſhelter, otherwiſe the damp will ſpoil them. If the weather proves fair, three days time will be long enough to dry them, provided they are carefully turned from time to time, that they may dry equally on every ſide. When they are perfectly dry they may be put up in boxes or ſacks, and preſerved in a dry place until they are ſhipped off, or otherwiſe diſpoſed of. The freſher theſe nuts are, the more oil is contained in them; ſo that the older they are, the leſs they are eſteemed.

Theſe trees do not produce their fruit on the young branches, or at their extremities, as moſt other trees do; but from the trunk, and the larger branches, come out the buds for flowers and fruit. While the trees are young, they do not produce their fruit in great plenty; for before the trees are eight years old, they reckon it a good crop to have twenty-eight or thirty pods on each tree at one gathering, eſpecially that at Midſummer; which is always a much worſe crop than the Chriſtmas ſeaſon, which is occaſioned by the much greater drought of the ſpring; for the autumns being the rainy ſeaſons, the Chocolate-trees produce a much greater quantity of fruit. When the trees are full grown and vigorous, they will ſometimes produce two hundred, or two hundred and forty pods at one ſeaſon: which will make ten or twelve pounds of Chocolate, when dried; ſo that it is a very profitable commodity, and can be managed with very little charge, when compared with ſugar. I have been credibly informed by a perſon of great worth and integrity, who reſided ſome years in America, that he has ſeen as much Chocolate gathered from one tree in a year, as hath been worth thirty ſhillings ſterling on the ſpot: ſo that the trouble of gathering and preparing for the market, being much leſs than for many other commodities which are manufactured in the Britiſh colonies, it is ſurpriſing it ſhould be neglected; eſpecially as it yields ſo large a ſhare of ſuſtenance to the wealthier inhabitants of thoſe colonies, that they cannot live comfortably without it, and purchaſe it from the French and Spaniards at a conſiderable price; which in time muſt greatly impoveriſh the colonies.

The Chocolate-trees, if planted on a good ſoil, and properly taken care of, will continue vigorous and fruitful twenty-five or thirty years: therefore the charge of cultivating a plantation of theſe trees, muſt be much leſs than that of Sugar; for although the ground between the rows of plants will require to be often hoed and wrought, yet the firſt working of a ground to make a new plantation of Sugar, Indigo, Caſſada, &c. is a larger expence than the after-work-

ings

Digitized by Google

THE

ings are. Beſides, Sugar-canes require as much labour in their cultivation, as any plant whatever; and ſince the inſects which deſtroy the Sugar-canes, have ſpread ſo much in the Britiſh colonies, nothing is a more uncertain crop than Sugar; for which reaſon, I think it would be greatly worth thoſe planters care, who are poſſeſſed of proper lands for the Chocolate trees, to make ſome ſmall trials at leaſt, to be convinced of the truth of this fact.

The leaves of theſe trees being large, make a great litter upon the ground when they fall; but this is not injurious, but rather of ſervice to the trees; for the ſurface of the ground being covered with them they preſerve the moiſture in the ground, and prevent its evaporating; which is of great uſe to the young tender roots, which are juſt under the ſurface; and when the leaves are rotten, they may be buried in digging the ground, and it will ſerve as good manure. Some planters let the pods, in which the Chocolate is incloſed, lie and rot in a heap (after they have taken the nuts out) which they alſo ſpread on the ground inſtead of dung. Either of theſe manures are very good, provided they are well rotted before they are laid on the ground; and great care ſhould be had, that no vermin ſhould be carried on the plantation with the dung.

Beſides the ordinary care of digging, hoeing, and manuring the plantations of Chocolate-trees, there is alſo another thing requiſite in order to their doing well; which is, to prune the decayed branches off, and to take away ſmall ill placed branches, wherever they are produced. But you ſhould be cautious how this work is performed; for there ſhould be no vigorous branches ſhortened; nor any large amputations made on theſe trees; becauſe they abound with a ſoft, glutinous, milky juice, which will flow out for many days whenever they are wounded, which greatly weakens the trees. However, ſuch branches whoſe extreme parts are decayed, ſhould be cut off, to prevent the infection from proceeding farther; and ſuch branches as are much decayed, ſhould be taken off cloſe to the ſtem of the tree; but this ſhould be performed in dry weather, ſoon after the crop of fruit is gathered.

Some people may perhaps imagine, that what I have directed, is a tedious laborious work, and not to be performed by a few ſlaves: but this is a great miſtake, for I have been credibly informed, that five or ſix negroes will cultivate a plantation of ten thouſand of theſe trees, provided they are properly inſtructed; which is a ſmall number, when compared to the quantity neceſſary to cultivate a Sugar plantation of the like extent of ground. And when the profits of both are compared, there will be a great difference: for, ſuppoſing we ſet the price of five ſhillings per annum, for the produce of each tree, when grown, (which I am of opinion is very moderate, conſidering what has been related;) then a plantation of ten thouſand trees will produce twenty-five hundred pounds a year; which, managed by ſix or ſeven negroes, without the expence of furnaces, &c. is a much greater profit than, I think, can be drawn from any other production.

In order to cultivate this plant in Europe, by way of curioſity, it will be neceſſary to have the nuts planted into boxes of earth (in the countries where they grow) ſoon after they are ripe; becauſe if the nuts are ſent over, they will loſe their growing quality before they arrive. Theſe boxes ſhould be placed in a ſhady ſituation, and muſt be frequently watered, in order to forward the vegetation of the nuts. In about a fortnight after the nuts are planted, the plants will begin to appear above ground; when they ſhould be carefully watered in dry weather, and protected from the violent heat of the ſun, which is very injurious to theſe plants, eſpecially while they are young: they ſhould alſo be kept very clear from weeds; which, if ſuffered to grow in the boxes, will ſoon overbear the plants and deſtroy them. When the plants are grown ſtrong enough to tranſport, they ſhould be ſhipped and placed where they may be ſcreened from ſtrong winds, ſalt water, and the violent heat of the ſun. During their paſſage they muſt be frequently refreſhed with water; but it muſt not be given them in great quantities, leſt it rot the tender fibres of their roots, which will deſtroy the plants; and when they come into a cool latitude, they muſt be carefully protected fom the cold, when they will not require ſo frequently to be watered: for in a moderate degree of heat, if they have gentle waterings once a week, it will be ſufficient.

When the plants arrive in England, they ſhould be carefully taken out of the boxes, and each tranſplanted into a ſeparate pot filled with light rich earth, and plunged into a moderate hot-bed of tanners bark, being careful to cover the glaſſes in the heat of the day, to ſcreen the plants from the ſun: they muſt alſo be frequently watered, but it muſt be done with caution, not to rot their roots. In this hot-bed the plants may remain till Michaelmas, when they muſt be removed into the bark-ſtove, and plunged into the tan, in the warmeſt part of the ſtove. During the winter ſeaſon the plants muſt be frequently refreſhed with water, but it muſt be given to them in ſmall quantities, yet in ſummer they will require a more plentiful ſhare. Theſe plants are too tender to live in the open air in this country, even in the hotteſt ſeaſon of the year; therefore muſt conſtantly remain in the bark-ſtove, obſerving in very warm weather to let in a large ſhare of freſh air to them, and in winter to keep them very warm. As the plants increaſe in bulk, they ſhould be ſhifted into larger pots: in doing of which, there muſt be particular care taken not to tear or bruiſe their roots, which often kills the plants; nor muſt they be placed in pots too large, becauſe that is a ſlow, but ſure death to them. The leaves of theſe plants muſt be frequently waſhed to clear them from filth, which they are ſubject to contract by remaining conſtantly in the houſe; and this becomes an harbour for ſmall inſects, which will infeſt the plants, and deſtroy them, if they are not timely waſhed off. If theſe rules are duly obſerved, the plants will thrive very well, and may produce flowers in this climate: but it will be very difficult to obtain fruit from them; for, being of a very tender nature, they are ſubject to many accidents in a cold country.

[When the trees are obtained, they may be increaſed by cuttings, in the ſame manner as the Gardenia.

According to Dampier, (in South America) they raiſe the young trees of nuts, ſet in fine black mould, and in the ſame places where they are to bear, which they do in four or five years. There are ordinarily from five hundred to two thouſand and upwards of theſe trees in a plantation or Cacao-walk; and they ſhelter the young trees with Plantains for two or three years, deſtroying them, when the Cacao-trees are large enough to endure the heat.

Browne ſays, that it requires a great deal of care, to raiſe the Chocolate-tree with ſucceſs. It is generally planted and cultivated in the following manner. Take a full-grown pod, that has lain by ſome days, and cut off the top at the pointed extremity, ſo that the ſeeds may be fully expoſed to view; then bury it two thirds or deeper in mould, in ſome moiſt ſhady place. In a few days the ſeeds begin to germinate: then take them out, and ſet them in beds, where the mould is rich, well divided and free, moiſt and properly ſhaded; diſpoſing them at ſuch diſtances as will leave room for the roots and branches to ſpread in. On each bed ſet one or two ſeeds, with the root-part downwards, ſcarcely covering them at the top: moiſten the mould gently about them, and cover the bed with ſome large leaves, to protect the young plants from the ſun; they ſhould be alſo guarded by ſome little ambient bulwark againſt heavy rains or blowing weather. They ſeldom require to be watered after the firſt day, but if this ſhould become neceſſary, it is beſt done, by laying a piece of wet cloth, or ſome watered weeds, gently round the plant: taking great care not to break off the ſeed-leaves, for the loſs of them would wholly prevent its further growth.

The Plantain-walks afford the moſt natural and agreeable ſhade for theſe plants, while young; but as

Digitized by Google

they riſe, they ſhould be ſupplied with a more ſubſtantial guard, to protect them from the inclemencies of the weather: theſe ought to be continued until the Chocolate-trees grow to full perfection, and even then muſt be removed with caution.

THEOBROMA GUAZUMA. See *Bubroma.*

THEODORA. See *Schotia.*

THEOPHRASTA. (*So named in honour of the celebrated Grecian Philoſopher and Botaniſt* Theophraſtus Ereſius.)

Lin. gen. n. 207. *Reich. n.* 221. *Schreb. n.* 271. *Juſſ.* 150. Ereſia. *Plum.* 25.

Claſſ. 5. 1. Pentandria Monogynia.

Nat. order of *Apocineæ* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, five-parted, permanent: *ſegments* oblong, ciliate at the edge.

COR. one-petalled, permanent: *tube* length of the calyx, bell-ſhaped: *ſegments* oblong, erect, ſpreading.

STAM. *Filaments* five, below the middle of the tube, inſerted into a membrane which ſurrounds the bottom internally, ſhorter than the corolla. *Anthers* acuminate.

PIST. *Germ* roundiſh. *Style* length of the ſtamens, thick. *Stigma* blunt, perforated.

PER. *Fruit* large, roundiſh, corticoſe, one-celled, many-ſeeded.

SEEDS oblong, ſhining, faſtened to a fleſhy juicy receptacle which is ſituated at the baſe.

ESSENTIAL CHARACTER.

Cor. bell-ſhaped, with oblong erect ſpreading ſegments. *Fruit* one-celled, very large, roundiſh, many-ſeeded.

SPECIES.

1. Theophraſta americana.

2. Theophraſta longifolia.
   Lin. ſpec. ed. Willd. 1. 824. *Jacqu. collect.* 4. 136.
   Leaves mucronate-toothed acuminate.

DESCRIPTIONS, *&c.*

1. Stem fruteſcent, one or two feet high, ſimple, erect, leafy from the middle to the top (like a frondoſe trunk, as in the Palms), tomentoſe-ferruginous, ſpiny. Leaves on very ſhort petioles, oppoſite, or inſerted into the ſtem in whorls; erect, elongated, attenuated at the baſe, blunt at the end, very rigid, ſerrate, the ſerratures ſpiny, alternately inflected and reflected. Spines ſtanding out ſmall but rigid, black at the outmoſt tip. Petioles preſſed cloſe to the ſtem, thick, rufous. Racemes ſhort, terminating, from the middle of the terminating leaves, many-flowered: peduncles numerous, curved, ſhort, one-flowered. Seeds black, hard, faſtened at the baſe but free above. The fruit is not properly a berry, nor is it a capſule, for it does not open; but it is corticoſe, and the greater part of it is often empty; when ripe it is yellow, and brittle, with the receptacle of the baſe juicy.—Native of South America; in dry coppices of Hiſpaniola [a].

2. This is very like the preceding, but yet it is diſtinct, in having the leaves attenuated at both ends, with the teeth acute and mucronate. In T. americana the teeth are ſhort, and the ſpace between them is excavated.—Native of America, at the Caraccas [b].

THESIUM (*of Pliny. Derivation unknown.*)

Lin. gen. n. 292. *Reich. n.* 315. *Schreb. n.* 410. *Gærtn. t.* 86. *Juſſ.* 75.

Claſſ. 5. 1. Pentandria Monogynia.

Nat. order of *Vepreculæ. Elæagni* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, turbinate, permanent, half-five-cleft: *ſegments* half-lanceolate, erect, obtuſe.

COR. none; unleſs the calyx internally coloured may be regarded as ſuch.

STAM. *Filaments* five, awl-ſhaped, inſerted into the baſe of the calycine ſegments, ſhorter than the calyx. *Anthers* roundiſh.

PIST. *Germ* inferior, growing upon the baſe of the calyx. *Style* filiform, length of the ſtamens. *Stigma* thickiſh, obtuſe.

PER. none. The calyx contains the ſeed in its bottom, and does not open.

SEED one, roundiſh, covered.

OBS. T. alpinum *takes one fifth from the fructification.*

ESSENTIAL CHARACTER.

Cal. one-leafed, into which the ſtamens are inſerted. *Nut* inferior, one-ſeeded.

Lin. ſyſt. 250. *Willd.* 1. 1217. *ſuppl.* 161. *Thunb. prodr.* 45.
Leaves awl-ſhaped mucronate, flowers axillary ſolitary.

DESCRIPTIONS, *&c.*

1. Root woody, branched, crooked, whitiſh, perennial. Herb rigid, and ſmooth, except that the edges of the leaves, bractes, and angles of the ſtem appear rough under the microſcope. Stems aſcending, angular, five or ſix inches high, little branched; clothed with numerous alternate linear leaves, all pointing one way, ſomewhat glaucous and ſucculent, entire. Flowers in ſpikes (moſtly branched, and ſometimes ſo compound as to form a panicle), ſolitary, on alternate erect pedicels; with three lanceolate acute bractes cloſe to each flower, in the lower part of the ſpike one being much larger than the other two. Tube of the calyx very ſhort and open, the margin acutely five-cleft, toothletted, white. Stamens very ſhort, oppoſite to the ſegments of the calyx. Style erect, equal to the ſtamens. Stigma emarginate. Seed oval, five-angled, ſtriated, bony, inveſted with the hardened baſe of the calyx. The herb is ſcarcely bitter, but a little ſaltiſh.

This without doubt is T. linophyllum, but when cultivated, as Linneus had it, the whole herb becomes luxuriant, the ſpike panicled and leafy, according to his definition. T. alpinum differs from this in having a long tubular calyx; otherwiſe they are much alike. The intermediate variety mentioned in Withering, ſeems to be the proper wild appearance of this plant [c].

Dr. Withering remarks that in a ſpecimen of T. alpinum from Switzerland, the leaves are not only broader than in our linophyllum, but ſtanding more upright they cloath and nearly hide the ſtem, which is never the caſe with our plant.

Having ſometimes four ſtamens, Scopoli refers this plant to the claſs Tetrandria, but it has much more frequently five ſtamens than four, and the calyx five-cleft than four-cleft.

Willdenow gives three varieties from Schrader and other German writers, which are owing to a difference of ſoil and ſituation. The panicle, he remarks, in this ſpecies, is formed of ſimple bracted racemes placed in the axils of the upper leaves.

Native of Europe, Siberia and Barbary: chiefly in a calcareous ſoil. It has been long obſerved in ſeveral parts of Cambridgeſhire; more lately in Suffolk and Norfolk; in Oxfordſhire by Dr. Sibthorp; in Dorſetſhire by Dr. Pulteney; in the Iſle of Wight by Dr. Stokes; and by the ferry leading to Portland iſland by Mr. Stackhouſe. It flowers in july.

2. Root perennial, fibrous, of a dirty white colour. Stems many, decumbent in a ring, ſometimes but ſeldom a little upright, half a foot long, round, ſmooth, commonly ſimple. Leaves linear, flat, acute, ſcattered, ſmooth, ſeſſile, numerous. The upper half of the ſtem becomes a looſe raceme, compoſed of ſhort ſcattered peduncles, naked at the baſe not axillary, having two or three leaflets above, and in theſe a ſingle ſubſeſſile flower, glaucous green on the outſide, and white within. The pedicel is elongated in the fruit [d].

The fruit is deſcribed by Gærtner as an inferior nut, formed from the indurated belly of the calyx, cruſtaceous, ſpherical, ſtriated with ſomewhat branched longitudinal nerves, one-celled, valveleſs. Seed globular, pale, faſtened by the baſe.

According to Haller, the flower is moſt frequently four-cleft, and ſometimes only three-cleft. Scopoli obſerved the flowers in Auſtria to be four-cleft, but in other ſpecimens to be three-cleft and five-cleft. Jacquin, in examining numerous plants, did not find any with five ſtamens; but obſerved the calyx to be moſt commonly cut into four ſegments, very ſeldom into three, with the number of ſtamens correſponding with the ſegments. The calyx is three or four-cleft, according to Pollich.

Scopoli diſtinguiſhes this ſpecies by the following marks: the buds proceed from the old ſtems; the leaves are more ſpreading, quite linear, nerveleſs, more rigid and fewer; the ſtems are half a foot long; the panicle equals half the length of the whole ſtem, and points one way; the fruits are oval, ſtriated, and furniſhed with a ſort of neck by the contraction of the calycine ſegments.

Native of the mountains of Italy, Germany, Auſtria, Switzerland, the South of France, Mount Atlas and Siberia.

It varies, according to Willdenow, with an erect and decumbent ſtem. The raceme is formed of one-flowered bracted axillary peduncles on the upper part of the ſtem.

[c] Smith. brit. & engl. bot.

[d] Jacqu. vind.

3. Root

Digitized by Google

3. Root annual. Stem herbaceous, erect, ſcarcely a hand in height, branching immediately from the baſe. Branches ſmooth, ſomewhat ſubdivided, angular, height of the ſtem. Leaves thick, an inch and half long, frequent, acute. Tube of the calyx ſcarcely any, not elongated as in T. alpinum. Capſules globular, wrinkled, the ſize of a Coriander ſeed. —Native of the kingdom of Tunis[e].

4. Native of the Cape of Good Hope, where it was found by Thunberg.

5. This is very ſquarroſe with the recurved leaves. Found at the Cape by Thunberg[f].

6. Stems ſimple, a hand high, hardiſh. Leaves alternate, narrower at the baſe, ſpreading. Raceme or ſpike terminating. Flowers alternate, ſeſſile, approximating; with two lateral bractes to each. Calyx five-cleft: ſegments lanceolate, concave, ciliate at the top and along the edge, with inflexed fibrils, covering the diſk of the calyx, like wool. Stamens from the ſinuſes of the calyx, inſerted into the cavity of it. Fruit ovate, much wrinkled, the ſize of a Coriander ſeed, villoſe at the tip within with the permanent calyx. Found at the Cape by Koenig[g].

7. This is a little ſhrub, having the appearance of Reſtis capenſis, and almoſt naked. Branches numerous, alternate, cluſtered, wand-like, ſimple, round, filiform. Leaves alternate, remote, very ſmall. Spikes terminating, two or three, alternate.—Native of the Cape[h].

8. Stem erect, ſtiff, ſomewhat angular, proliferous, three feet high, the thickneſs of a quill. Leaves even, very ſmall and remote. Spikes oblong, the thickneſs of the little finger. Flowers diſtinct, with three acuminate bractes membranaceous at the edge. —It is very diſtinct from T. funale; the ſtem not being flexible like a cord; the ſpikes not very narrow; the bractes between the flowers not ſlender like a needle.—On mountains near the Cape[i].

9. Stems ſhrubby hard. Branches alternate, remote, the upper ones gradually longer. Leaves alternate, ſmall, awl-ſhaped, mucronate. Heads of flowers terminating, with a branch growing out below. Segments of the flowers very ſharp-pointed, and internally villoſe their whole length.—Native of the Cape[k].

10. Stem ſhrubby, branched, angular as in Broom. Leaves alternate, remote, ſhorter than the interſtices, glued at the baſe and decurrent. Umbels peduncled compound, with an involucre and involucrets. Calyx even within.—Native of the Cape[l].

11. Root perennial. Leaves alternate, oval-lanceolate, quite entire. Branches alternate, at the top of the ſtem. Umbellets racemed, terminating, with a ſmall four-leaved involucret. Florets five or three. —Native of Virginia and Pennſylvania, in dry paſtures[m]. Introduced in 1782, by John Hope, M. D. It flowers here in june[n].

12. Habit of Salſola. Leaves ſo ſhort, that at firſt ſight it ſeems to have none. It is a very brittle plant. Found at the Cape of Good Hope by Thunberg[o].

13. This very much reſembles T. capitatum, but the heads are on a long naked peduncle. Flowers bluntiſh, villoſe on the inſide only at the tips. Leaves roughened with a triple angle having cartilaginous teeth. Native of the Cape[p].

14. Stem ſomewhat woody, a foot high, the whole panicled as in Galium. Leaves minute, linear, alternate, the upper ones awl-ſhaped. Flowers minute, peduncled. Calyx inferior, three, four or five-cleft, but removed by a ſpace, whence it is not a proper one. True calyx ſuperior, as in its congeners. Fruit like that of the Coriander. Many of the flowers are abortive.—Native of the Cape.

15. Stem ſomewhat woody, erect, ſlightly angular, four feet high, even. Leaves alternate, ſeſſile, embracing, cordate, quite entire, ſharpiſh, even, thickiſh, an inch long. Racemes terminating. Flowers minute mixed with larger ovate bractes.—Native of high mountains near the Cape[q]. Introduced in 1787, by Mr. Francis Maſſon[r].

16. Peduncles three-flowered, ſometimes bifid or trifid, much divaricated. Found at the Cape by Thunberg[s].

17. Branches dichotomous at top. Leaves alternate, rounded-ovate, even. Flowers pedicelled. It has the appearance of an Euphorbium.—Native of the Cape[t].

18. This is a tree with compreſſed ancipital branchlets. Leaves on ſhort petioles, blunt with a point, ſmooth. Racemes from the axils of the branches, erect, compreſſed, ſcarcely longer than the leaves. Number of parts in the flower four or five. There does not ſeem to be any neceſſity to ſeparate this from the Theſiums.—Native of the Cape.

19. This is ſingular in having the leaves ſpreading, channelled, terminating in a ſpine. Found at the Cape by Thunberg[u].

Very ſmooth, ſtem grooved, leaves ſagittate lanceolate ſubſerrate, ſilicles two-lobed.

DESCRIPTIONS, *&c.*

1. Stems a ſpan high, hard, branched, by age becoming red, as do alſo the leaves, which are on ſhort petioles. Flowers ſmall, red, with ovate entire petals. Stamens red. Anthers yellow. Style ſhort, yellow. Stigma yellow, flat at top. Seeds ovate, yellowiſh, ſomewhat wrinkled, ſhining, faſtened to a ſickle-ſhaped partition[x].]

It is a biennial plant, riſing eight or nine inches high, branching out towards the top. Leaves thick, blunt, of a grayiſh colour, oppoſite, ſeſſile, having a bitter warm taſte. The flowers are produced in looſe terminating ſpikes; they are ſmall and of a purple colour. Silicles heart-ſhaped, of a fine green colour, having three or four ſmall, oblong, yellowiſh ſeeds in each cell, which have an acrid taſte. It flowers in june, and the ſeeds ripen in auguſt.

[Native of Carniolia. Cherlerus was the firſt who obſerved this plant in Zuinger's garden[y]. Mr. Miller cultivated it in 1739. He makes it a native of Sicily.

2. Stems herbaceous, diffuſed, branched, very ſmooth, as is the whole plant. Leaves two inches long; the lower ones narrowed a little towards the baſe and ſeſſile; the upper oblong, heart-ſhaped, embracing, ſhaped almoſt like thoſe of Braſſica orientalis; the uppermoſt narrower at the baſe, cordate-oblong, embracing, for the moſt part quite entire but ſometimes remotely toothletted; all veinleſs. Raceme terminating, with a branch growing out beyond it. Flowers at firſt corymbed, afterwards racemed. Calyx-leaves lanceolate. Petals longer than the calyx; borders roundiſh, purple, two ſcarcely larger than the other two. The ſilicle has a wide membranaceous margin, and an awl-ſhaped permanent ſtyle one fourth only of the length of the ſilicle; it has a ſinus at each end. The petals being ſcarcely irregular, and the ſilicle being altogether that of a Thlaſpi, this plant belongs rather to this genus than to Iberis, where Linneus had placed it. It ſeems difficult to conceive why Forſkahl made it a Subularia, with which it has nothing in common[a].

3. Root annual, ſmall. Herb ſmooth. Stem a foot or more in height, upright, round, leafy, with ſeven or eight membranaceous edges, and having a few branches at top. Leaves bluntiſh, diſtantly toothed, arrow-ſhaped at the baſe, embracing, ſomewhat glaucous beneath. Flowers ſmall, in racemes. Peduncles alternate, nearly horizontal, one-flowered. Petals white, entire, twice the length of the calyx. Silicle length of the peduncle, very broad, orbicular, deeply notched, a little convex in the middle on each ſide, ſmooth, having a very wide winged margin[z]. Seeds from five to ſeven (or four to nine) in each cell, ovate, narrowed and beaked towards the navel, ſcored with furrows that are parallel to the margin and very minutely crenulated, ſomewhat ſhining and of a very dark cheſtnut colour[b]. Gærtner obſerves that the ſtriated ſeed is rare and perhaps the only inſtance in this family.

This plant is obviouſly diſtinguiſhed, as Ray obſerved, by its ſmoothneſs, and large flat round pods, whence it acquired the name of Penny-creſs. The ſeeds are ſaid to produce twice as much oil as linſeed. They have an acrimony approaching to that of Muſtard, but with an unpleaſant flavour ſomewhat like Garlic. The whole plant has alſo the taſte of Garlic, ſo that when cows eat it, their milk gets a bad taſte.

It flowers at the beginning of june, and the ſeeds are ripe by the end of the month, hence they are not liable to be ground with corn, to which they might otherwiſe communicate their ill flavour[c].

Native of Europe and Japan, in corn-fields, eſpecially in a ſtrong moiſt ſoil, ſometimes in gravel. Ray obſerved it in Eſſex, Suffolk and Staffordſhire, Mr. Miller near Godalmin in Surry, Mr. Curtis, near Hampſtead, Mr. Roſe near Norwich, Mr. Relhan in Waterbeach-fen, Cambridgeſhire, Mr. Morton in Wadenhoe-field, Northamptonſhire, Dr. Sibthorp and Dr. Goodenough in Oxfordſhire, Dawſon Turner, Eſq. and Mr. Sowerby about Ayleſbury.

4. The whole plant has the ſmell of garlic, and a taſte ſlightly acrid; it is ſmooth and annual. Root-leaves many, ſpatulate, on long petioles, quite entire or ſlightly toothletted below: the ſtem and branch-leaves are acutely haſtate and ſeſſile. Stems few, upright, round, half a foot high, little branched, ending in fruiting racemes as long as themſelves. Flowers corymbed, ſmall. Petals white, ſcarcely bigger than the calyx. Silicles obcordate-ovate, obtuſe, gibbous on both ſides but eſpecially on the back, with ſcarcely any margin. Seeds commonly three in each cell, ſomewhat acrid[d]. It reſembles the preceding, but the ſilicles are ovate and ventricoſe with little or no margin[e]. Native of Auſtria and Germany.

5. This is an annual plant, with an upright branched ſtem, hiſpid with white hairs. Leaves pubeſcent; the lower ones obtuſe, the upper ones acute. Flowers racemed, pedicelled. Bractes ovate, toothed, longer than the pedicel. Flower the ſize of Braſſica oleracea. Calyx-leaves pubeſcent, linear, preſſed cloſe, deciduous. Corolla pale yellow; claws linear, longer than the calyx; border elliptic, netted-veined, quite entire, rounded at the top. Style permanent, awl-ſhaped, longer than the ſilicle; which is large, triangular, gibbous on both ſides in the middle, hirſute, two-winged; wings ſtiffiſh, increaſing above, tranſverſely ſtriated. Seeds numerous, ſmall, ruſeſ-

[x] Scopoli. [y] Moriſon. [a] Vahl. [z] Curtis and Smith. [b] Gærtner. [c] Curtis and Withering. [d] Jacqu. miſc. [e] Willdenow.

Digitized by Google

cent. It flowers early in ſpring. Native of Barbary near Mayane, on the borders of fields[f]. Desfontaines has made this plant a diſtinct genus, under the name of Pſychine, from ψυχη a butterfly; the winged ſeed-veſſel having ſomething of the ſhape of that inſect: but it has nothing that entitles it to be conſidered as generically ſeparate from the other Thlaſpis.

6. This alſo is annual, and reſembles Iberis ſaxatilis[g]. Stems trailing, hard and woody. Leaves a little fleſhy and entire. Flowers ſmall, fleſh-coloured. Silicles large, convex below, concave above, with a leafy margin, and toothed at their upper edge[h].

Native of the South of Europe: Germany, Auſtria, the South of France, and Italy.—Cultivated by Mr. Miller in 1748[i].

7. This is diſtinguiſhed by Ray from the campeſtre, with which it has been confounded, by having the flowers three times as large, the ſilicles longer and more hairy. Linneus's plant is certainly diſtinguiſhed in having the ſilicles more oblong, little gibbous, hirſute, by no means glandular-dotted. It is probably biennial[k].

According to Villars, the ſtems are many, ſimple and decumbent at bottom. Lower leaves entire, with ſome hairs on their edges; ſtem-leaves more villoſe. Flowers white, ſmall. Silicles hirſute, rather ſmall.

Native of Italy, the South of France and Auſtria. Ray obſerved it on the mountains of Wales and elſewhere.]

Mr. Miller ſays it grows naturally on the ſide of a bank beyond Wandſworth in the road to Putney; but he probably miſtook a variety of the campeſtre for it, as other Engliſh botaniſts have done. He deſcribes it as having a perennial creeping root; the lower leaves oblong and hoary, ſlightly ſinuated but not indented on their edges; the ſtalks five or ſix inches long, and bent towards the ground; the flowers rather larger than thoſe of campeſtre; the pods hoary but not hairy. It flowers in may, and the ſeeds ripen in july.

8. Root annual, ſimple. Herb more or leſs pubeſcent. Stems a foot or more in height, upright, round, very ſlightly angular, thickly cloathed with leaves, undivided except at the top, where it ſeparates into ſeveral (ſeven or eight) branches, and forms a panicle: above the branches it is naked. Root-leaves oblong-ovate, on long flat petioles, ſometimes pinnatifid at the baſe, but for the moſt part entire, ſoon decaying: ſtem-leaves ſagittate, embracing, alternate, toothed or ſometimes quite entire. Peduncles horizontal, round, a little longer than the ſilicles. Flowers very ſmall and white, in long upright racemes. Petals ſpatulate, a little longer than the calyx, entire. Silicle roundiſh or ovate, convex on the lower, concave on the upper ſurface, the border very wide at the top, emarginate, having glandular dots on both ſides, commonly ſmooth but ſometimes hairy, containing one ſeed in each cell[l].

Native of Europe and Barbary, in corn-fields. About Comb-wood near Kingſton, in Gunnerſbury-lane near Ealing, South Leigh and Stanton-Harcourt in Oxfordſhire, Dorſetſhire, &c. Flowering in june.

β. A variety was obſerved by Ray near Beccles in Suffolk, with ſmooth broader leaves not ſo tapering to a point, and ſmooth pods.

γ. Another variety, ſoft like velvet to the touch, with the ſilicles cottony in a ſlight degree, has been miſtaken for the hirtum of Linneus; which is not above half ſo high as this, and has the root-leaves inverſely ovate and broad at the end; the ſilicles in that are hirſute.

This variety has been obſerved on Dartmoor[m]: and by Mr. Dawſon Turner near Warrington.

The campeſtre as well as the arvenſe has been uſed for the ſame purpoſes as Muſtard-ſeed. This has not ſo much of the Garlic flavour as the arvenſe[n].

9. Stems erect, a finger or a hand, ſeldom a foot in height, ſingle or in a cluſter from the ſame root, not branched, round and ſmooth. Root-leaves in a tuft forming a roſe, wedge-obovate, running into the petiole, ſometimes very ſlightly ſubſinuate, bright green; ſtem-leaves alternate, embracing, cordate-lanceolate or ovate, quite entire or very ſlightly crenulate: all glaucous and very ſmooth. The flowers at firſt form a ſmall umbel, but afterwards are drawn out into a long raceme. Calyx browniſh, with a white margin. Petals twice as long as the calyx, blunt at the end, white, nearly of the ſame ſize as in the arvenſe. Silicles cordate, oblong, as in Burſa paſtoris, convex on one ſide, flat on the other[o].

Linneus remarks, that the corollas are almoſt equal or regular, and that the fruit together with the habit or appearance of this genus diſtinguiſh it from Iberis[p].

β. Willdenow conſiders the præcox of Wulffen in Jacquin's Collectanea as a variety of this, and refers the montanum of Scopoli and Lepidium, n. 518. of Haller to it. He remarks, that in the montanum the leaves are oblong, ſeſſile, and ſcarce apparently ſagittate; whereas in præcox they are deeply ſagittate and glaucous. The ſilicles in the former are obtuſely cordate, in the latter deeply cordate. But he does not diſcern any certain limits between them; for the leaves in montanum are ſometimes more deeply ſagittate with blunt earlets, and that on the ſame plant. —Probably the montanum of other authors beſides Scopoli may be referred to this plant. Dr. Smith ſuſpects that this præcox may be the ſame with the alpeſtre: to which the montanum of Miller, n. 8. muſt alſo be referred.

Native of Germany, Auſtria, the South of France and Italy.

10. A ſmall ſpecies, ſcarcely more than four or five inches high: differs from Thlaſpi perfoliatum in the ſize of the petals and perennial root, which is ſlender, ramified, and produces ſeveral circles or roſes of leaves, and afterwards ſeveral ſtems, which are ſmooth, ſimple, of a pale green, and ſometimes procumbent: the leaves are alternate, ovate, ſmooth and ſlightly pointed: the flowers are of moderate ſize and milk white, ſtanding in cluſters on the top of each ſtem[q].

11. Root annual, fibrous. Stem branched, except in a barren ſoil, a ſpan high, ſpreading, roundiſh, ſtriated, ſmooth, leafy. Leaves ſmooth, glaucous, obſcurely toothed: root-leaves petioled, ovate, obtuſe; ſtem-leaves alternate, embracing, cordate, ſubſagittate, bluntiſh. Corymbs terminating, ſmall, cloſe; afterwards racemed, very long. Calyx ſpreading, reddiſh. Petals white, twice as long as the calyx, obtuſe, entire. Silicle ſmooth, obcordate, with the lobes far ſurpaſſing the very ſhort ſtyle. Stigma headed. Seeds many[r]: according to Pollich, four in each cell.—Linneus ſays, that the ſtem is ſmooth, the corolla white and hardly larger than the calyx, the ſtamens longer than the flower, and the ſilicle like that of the common Shepherd's-purſe.—According to Withering, the ſtem is about eight inches high, upright and ſimple, except in a rich ſoil and in gardens, where it is branched; the lower leaves ovate, petioled; the others embracing, glaucous.

Native of Germany, Switzerland, Auſtria, the South of France, Italy and England. Found among the ſtone-pits between Witney and Burford, by Bobart, and on Burford downs by Sibthorp. It flowers in april and may.

12. Root very long, branched, commonly ſaid to be perennial, but doubtful whether it be more than biennial. Stems ſeveral, almoſt upright, a ſpan high, ſimple or very ſeldom divided, round, ſmooth, leafy. Leaves ſmooth, glaucous, quite entire, ſcarcely toothed: root-leaves numerous, forming a thick tuft, petioled, ovate or obovate, obtuſe; ſtem-leaves alternate, ſeſſile, ſlightly embracing, ſagittate, ſharpiſh. Corymbs as in the preceding. Petals white, varying in ſize. Silicle ſcarcely obcordate, but rather obovate, retuſe, gibbous, with the ſtyle lengthened

out

out and prominent far beyond the lobes, mucronate. Seeds ſeveral (three or four) in each cell[t].

One ſtem, ſeldom branched, ariſes from the tuft of leaves, and flowers early in ſummer; the lateral ſtems are afterwards numerous, moſtly unbranched, and produce a ſecond crop of flowers in july and auguſt, as in Iberis nudicaulis. The whole herb is glaucous, ſomewhat ſucculent, bitter and pungent in taſte and ſmell, yet horſes and cows ſeem to feed it down.—This plant is certainly the montanum of Hudſon: but the Linnean montanum has much larger petals, leaves more entire, a creeping root, and only one or at moſt two ſeeds in each cell. Alpeſtre of Hudſon is really the perfoliatum of Linneus, as it ſtood in the firſt edition of the Flora Anglica, and is an annual branched plant, with dentated leaves and ſmall flowers[t].

It is remarked in Engliſh Botany, that Dr. Withering (in his ſecond edition), having taken up theſe plants from Hudſon, has much confuſed their hiſtory. To this acculation Dr. Withering, with a degree of ingenuity not very common among authors, pleads guilty, in the third edition of his arrangement: in which he ſays that the ſpecies have been there given without any view to Mr. Hudſon's opinions, and are founded on the indiſputable veracity, and well known accuracy of Ray, who (ſyn. 305. n. 4. and 6.) records two ſpecies, referring to the ſame figures which Linneus (in Spec. plant.) has quoted to T. montanum and alpeſtre; ſo that he muſt believe Ray to have ſeen both thoſe ſpecies. He alſo particularly notices the creeping root of T. montanum; which in Engliſh Botany is treated as a miſtake; and ſo it certainly muſt be, upon the ſuppoſition that Linneus's montanum is not a native of England, as there preſumed.

Gerard and Jacquin unite this plant with the perfoliatum. Haller ſeparates them. Willdenow thinks it may be a variety of that. Gouan ſeems to have deſcribed the right plant. The ſtem, ſays he, is ſimple and ſtraight. In a garden it became ſmaller, but perennial and evergreen, and produced ſeveral ſtems from the ſame root, ſome upright, others diffuſed.

Native of Germany, Switzerland, Auſtria, the South of France, Italy and England. Mr. Ray found it near Settle in Yorkſhire (where Mr. Curtis and Dr. Smith have alſo gathered it,) and between that place and Malham. At Matlock, where it grows abundantly on the lime-ſtone rocks and about the lead mines, with Arenaria verna, as obſerved by Mr. Curtis near Settle. Gathered by Dr. Smith, july 4th, 1792. Dr. Withering thinks it highly probable that the plant found by Merret in Yorkſhire, and by Nicholſon on moſt limeſtone paſtures in Weſtmoreland and Cumberland, is the true alpeſtre.—He refers the plant found by Ray near Settle and in many paſtures between that and Malham, by Curtis on the road from Settle to Malham, and by Mr. Woodward on Ingleborough, to the montanum; but they are all probably the alpeſtre.—It flowers in june and july.

13. Root annual, fibrous. Stem about a foot high, upright, round, branched, leafy, rough. Root-leaves pinnatifid, the ſegments varying much in form. Stem-leaves oblong, embracing, toothed. All more or leſs hairy. Flowers in corymbs, lengthening out into racemes. Calyx ſlightly hairy, with membranous edges. Petals white, a little longer than the calyx, rounded at top. Silicles ſmooth, deltoid-obcordate, without any margin, terminated by a ſhort ſtyle. Seeds numerous, yellowiſh, on pedicels which connect them with the edge of the partition[u].

Gærtner remarks, that the valves are keeled, and attenuated into a margin above only; that the partition has frequently a perforation in the middle; and that there are about twelve ſeeds in each cell, which are ovate, beaked, ſmooth and ſaffron-coloured.

This plant, which grows naturally in moſt parts of the world, is a ſtrong inſtance of the influence of ſoil and ſituation; ſometimes not being more than two or three inches high, when it flowers and perfects its ſeeds, whilſt in other ſituations it attains the height of as many feet. On walls and in dry ſituations the root-leaves are more deeply divided, and the ſegments become much narrower: in cultivated ground they are broader and leſs jagged: in a dry barren chalk the plant becomes very ſmall with a ſingle undivided ſtem, and the leaves all entire.

March and april are the months in which it is moſt generally found in flower; yet like the Groundſel (Senecio vulgaris) and Poa annua, it may be found in this ſtate at almoſt any time of the year. Small birds are very fond of the ſeeds[x].

Dr. Withering remarks, that this and the other ſpecies of this genus begin to flower long before they have attained their full ſize; the flowers at firſt forming a corymb, which after a while ſhoots out and aſſumes the form of a long ſpike-like raceme. The ſtem alſo, at firſt ſimple, in time becomes branched; the firſt branches iſſuing from its upper part.

14. This is an annual plant a ſpan in height. Stem upright, round, grooved, branching at top into corymbs. Leaves ſeſſile, very ſlightly ſerrate, veined, very ſmooth. Corymbs lengthened into racemes. Flowers ſmall, white. Silicles ovate, roundly emarginate at the top, with the lobes divaricating produced acute, reſembling the ſeeds of Ceratocarpus.—Native of the ſalt plains of Siberia[y]. Introduced in 1779, by Jonas Dryander, M. A. It flowers in july[z].]

PROPAGATION AND CULTURE.

Sow the ſeeds where the plants are to remain, either in ſpring or autumn; but the latter ſeaſon is to be preferred. When the plants come up, thin them where they are too cloſe, and keep them clean from weeds.

If the campeſtre and arvenſe be cultivated for uſe, ſow them thin upon beds of light ground; hoe and thin them as directed for carrots, onions, &c. ſo as to leave them three or four inches apart.

If the ſeeds of any of the ſorts be permitted to ſcatter, the plants will come up without care.

13. Shepherd's Purſe is a common weed every where. It increaſes ſo faſt by ſeeds, that a garden is not eaſily cleared of it, when they are permitted to ſhed. There are generally four crops of this plant from ſeed in a year; it cannot therefore be too ſoon or too carefully rooted out of a garden, [which is eaſily done by hoeing in dry weather. In fallows it is inſignificant, and affords food for cattle and ſheep.

SPECIES.

1. Thoa urens.
Aubl. guian. p. 875. *t.* 336.

DESCRIPTION, *&c.*

This is a ſhrub, riſing with a tortuous ſtem to about the length of ten feet, and emitting ſeveral twiſted and climbing branches upon the neighbouring trees: the bark is rough and greyiſh: the wood white and ſpongy: the leaves oppoſite, ſmooth, green, entire, and oval, terminating in a ſharp point: the largeſt are about five inches and a half long, and about three inches wide: the ſpikes of male flowers ſpring from the boſoms of the leaves and the tips of the branches, and on each ſide the baſe of the male flowers is a female one: the female flowers are each ſucceeded by a ſmooth reddiſh capſule, under the bark of which is found a dry ſubſtance compoſed of ſtiff recumbent briſtles which ſeparate eaſily and cauſe a ſevere itching when rubbed on the ſkin. The native name of the plant is Thoa[a].

Humbertia madagaſcarienſis. *Lamarck encycl.* 2. 353. *t.* 103.

DESCRIPTION, *&c.*

This is a tree with a hard wrinkled bark: the branches are round, ſilky towards the top, terminated by leaves and flowers in bundles. Leaves ſcattered, obovate-lanceolate, obtuſe, very ſmooth, with a ſtout midrib; quite entire, often emarginate: petioles ſhort, channelled, when young ſilky. Stipules none. Flowers axillary, ſolitary, large and handſome, nodding a little, on roundiſh peduncles thickened at the top, ſilky towards the baſe, having in the middle two ſmall acute ſilky oppoſite bractes[b].

According to Commerſon's manuſcripts, the fruit is a drupe; but Juſſieu and Lamarck conſider it as a two-celled capſule, with two ſeeds in each cell[c].

Native of Madagaſcar, where it was found by Commerſon.

Lin. ſpec. ed. Willd. 2. 202. *Swartz prodr.* 57. *deſcr.* 1. 614. *Brown. jam.* 190. *n.* 1.

DESCRIPTION, *&c.*

Trunk from ten to twenty feet high, ſwelling at the baſe, unarmed. Fronds terminating, palmate-plaited, from one to two feet long: *diviſions* lanceolate, nerved and marked with lines, rigid, almoſt equal. Stipes longer than the leaves, round-flatted, ſmooth, flexile, unarmed. Spadix terminating, almoſt upright, two or three feet long, panicle-branched: branches alternate, ſubdivided, ſpreading: branchlets or ſpikes decuſſated, oppoſite or in threes. Flowers pedicelled, oppoſite or in threes, placed on the rachis, ſmall, hermaphrodite. Berry roundiſh, the ſize of a ſmall pea, almoſt juiceleſs. Kernel white within, red in the middle.

Native of Jamaica and Hiſpaniola, on the coaſt and in dry places[d].

Browne ſays, that this tree covers whole fields in many parts of Jamaica; that it grows both in the rocky hills, and low moiſt plains near the ſea, but ſeems to thrive beſt in the former. It ſhoots by a ſimple ſtalk, and riſes generally from four or five to ten or fourteen feet in height. It is always furniſhed with leaves in form of a fan, ſuſtained by ſlender compreſſed footſtalks, and bears a great abundance of ſmall berries, which ſerve to feed both the birds and beaſts of the wood, when they are in ſeaſon. The trunk ſeldom exceeds four or five inches in diameter: it is much uſed for piles in wharfs and other buildings made in the ſea; for it ſtands the water well, and is never touched by the worms. The foot-ſtalks of the leaves, ſplit and pared, ſerve to make baſkets, bow-ſtrings, ropes, &c. where ſtrength and toughneſs are required. The leaves are called Thatch, and are uſed as ſuch, eſpecially for out-houſes, and ſtand the weather many years; but ſuch coverings are apt to harbour rats and other vermin.

DESCRIPTIONS, *&c.*

1. The common Arbor-vitæ has a ſtrong woody trunk, which riſes to the height of forty feet or more: the bark, while young, is ſmooth and of a dark brown colour, but as the trees advance, the bark becomes cracked and leſs ſmooth: the branches are produced irregularly on every ſide, ſtanding almoſt horizontal, and the young ſlender ſhoots frequently hang down; theſe branches ſtand but thin, and the younger branches only have leaves, ſo that when the trees are grown large, they make but an indifferent appearance, being ſo thinly clothed with the leaves. The young branches are flat, and the ſmall leaves are placed over each other like the ſcales of fiſh. The flowers are produced from the ſide of the young branches, pretty near to the foot-ſtalk: the males grow in oblong katkins, and between theſe the females are collected in form of cones. When the former have ſhed their farina, they ſoon drop off; but the latter are ſucceeded by oblong cones or ſtrobiles, having obtuſe ſmooth ſcales, containing one or two oblong ſeeds.

[Gærtner deſcribes the ſtrobile as elliptic-globular, with coriaceous ſcales, marked on the outſide under the tip with a ſmall indiſtinct tubercle, within ſimply concave. Seeds (nuculæ) oblong, of a bay colour, ſurrounded on each ſide with a widiſh membranaceous wing, emarginate at the top and bottom.

Native of Siberia and Canada, where it is very plentiful, but not much farther ſouth. The moſt ſoutherly place that Kalm ſaw it in, was a little to the ſouth of Saratoga, in the province of New York, and near Caſſes, in the ſame province, which places are in 42°. 10′. north latitude. Mr. Bartram found a ſingle tree in Virginia, near the falls in the river James. Dr. Colden alſo ſaw it in many places round his ſeat of Coldenham, between New York and Albany, in about 41°. 30′. north latitude. The French in Canada call it *Cedre blanc.* The Engliſh and Dutch in Albany call it the White Cedar.

It generally ſucceeds in grounds where the roots have ſufficient moiſture. In ſwamps and marſhes it grows pretty tall. Stony hills, and places where many ſtones lie together, covered with moſſes, ſeem to ſuit it next to the former ſituations. When the ſea ſhores are hilly, and covered with moſſy ſtones, it ſeldom fails to grow on them. It is likewiſe ſeen now and then on hills near rivers and other high grounds; but ſuch places commonly carry a ſouriſh water with them, or receive moiſture from the upper countries. In very dry places it never comes to any conſiderable ſize. It is pretty frequent in the clefts of mountains, but cannot grow there to any remarkable height or thickneſs. The talleſt trees in the woods of Canada are about thirty or thirty-ſix feet high. A tree of ten inches diameter had ninety-two rings round the ſtem; and another of fourteen inches had a hundred and forty-two rings.

Being reckoned the moſt durable wood in Canada, incloſures of all kinds are ſcarcely made with any other wood; eſpecially the poſts which are driven into the ground. The paliſades round the forts are made of this wood. It furniſhes planks or boards for houſes. The thin narrow pieces which form the ribs and bottom of the bark-boats commonly uſed in Ca-

* Linn. ſpec.

Digitized by Google

nada are taken from this tree, becauſe it is pliant enough for the purpoſe, eſpecially whilſt it is freſh, and becauſe it is very light. It is reckoned one of the beſt woods for the uſe of the lime-kilns. The branches are uſed all over Canada for beſoms, which the Indians bring to the towns for ſale. The freſh branches have a peculiar agreeable ſcent, which is perceived ſtrongly in houſes where ſuch beſoms are uſed. Mr. Miller ſays that the leaves have a rank oily ſcent when bruiſed.

This Thuja is uſed in Canada for rheumatic pains; the leaves being made into a ſalve with hog's-lard, and applied to the part. For violent wandering pains they uſe the cones with four-fifths of Polypody, both powdered coarſely, made into a poultice with water milk-warm, and wrapped round the body, with a cloth between, to prevent its ſcorching the ſkin. A decoction of the leaves is employed by the Indians in coughs and intermitting fevers.

The common Thuja flowers early in the ſpring, and the ſeeds are ripe towards the end of ſeptember. Where the trees grow thick they ſeldom bear ſeeds; but a ſingle tree, where the air can freely come at it, is always full of ſeeds[f].

The great value of the wood for bowls, boxes, cups, mortars, peſtles, and various works of the turner and cabinet-maker, make this tree juſtly claim a place in plantations. It bears our ſevereſt winters, and ſoon arrives at a middling ſtature[g].

Cluſius ſays, that he firſt ſaw this tree in the royal garden at Fontainbleau, whither it was ſent from Canada as a preſent to Francis the Firſt, and that he believed this to have been the firſt tree of the kind which had been brought to Europe.

It was cultivated in England before 1596; for Gerarde ſays, "it groweth in my garden very plentifully, and it flowreth about may. The new writers do terme it *Arbor vitæ*, in Engliſh the tree of life; I do not meane that, whereof mention is made in Geneſis."]

2. The branches of the Chineſe Arbor vitæ grow cloſer together, and being much more adorned with leaves, which are of a brighter green colour, make a much better appearance than the former. The branches croſs each other at right angles. The leaves are flat, but the ſingle diviſions are ſlender, and the ſcales are ſmaller, and lie cloſer over each other than thoſe of the firſt ſort. The cones (ſtrobiles) are alſo much larger, of a beautiful gray colour, and their ſcales end in acute reflexed points.

[Gærtner deſcribes them as ovate, obſcurely four-cornered, compoſed of oblong, thick, ſuberoſe ſcales, oppoſite by pairs, armed on the outſide below the tip with a recurved little hook, very ſmooth within, and having a double little excavation near the baſe. The little nut is bony, globular, one-celled, valveleſs, covered with a thin epidermis of a rufeſcent bay colour, produced on each ſide into a very narrow ſcarcely perceptible margin. There is no proper receptacle except the cavities of the ſcales wherein the nuts lie. Seed elliptic-globular, pale.

Native of China and Japan.—It was cultivated by Mr. Miller in 1752[h].] According to him the ſeeds were firſt ſent to Paris by ſome of the Miſſionaries in China.

[3. Height from two to ſix feet, in a dry ſoil a low ſhrub. Branches round, alternate, ſpreading at a right angle. Fronds roundiſh at the baſe and branched: branches oppoſite, branchletted, jointed, the laſt and thoſe of the branchlets gradually ſmaller, widening a little upwards, having a hollow at the top for the next joint, marked with a line on each ſide. Leaves none, but ſmall ſcales (four or ſix) at the top of the joints, ſharp and unequal. At the baſe of theſe are ſcarcely viſible glands. The male ſtrobile is ſmall, ovate, nodding a little, obtuſely four-cornered: ſcales in four rows, commonly four in each, pedicelled, peltate, pale yellow; anthers three or four, ſeſſile, roundiſh, under each ſcale. Female ſtrobile ſolitary at the end of the branches, four-cornered, with the corners blunt: ſcales four, woody, thick, cordate, on the outſide longitudinally hollowed in the middle, convex within, opening from top to bottom; two of them bigger, oppoſite, fertile, the other two narrower, barren. Seeds ſmall, with a membranaceous margin.

Native of Mount Atlas, and barren hills in Barbary.

Brouſſonet affirms that the reſin commonly called gum Sandarack, flows from this tree in the kingdom of Morocco. It is totally different from Thuja cupreſſoides of Linneus's mantiſſa; that has the ſcales imbricate, and a ſmooth ſtrobile, three times as large as that of this ſpecies[i].

4. This is a very large and lofty tree, and the handſomeſt of all the evergreens. Branches and branchlets alternate, compreſſed, covered with imbricate leaves, which are diſpoſed by threes; they are ovate, obtuſe, entire, compreſſed, above ſhining green and ſmooth, convex with a groove in the middle, beneath concave, margined, ſnow white.

Native of Japan; obſerved by Thunberg[k]; planted every where by the road ſide in Fakonie. He conſiders it as the handſomeſt of the evergreen trees, on account of its height, its ſtraight trunk, and its leaves of a ſilvery hue on the under part. He ſent over to Holland ſeeds and growing plants of it[l].]

PROPAGATION AND CULTURE.

Theſe trees may be propagated by ſeeds, layers, or cuttings. The firſt ſort is commonly propagated by cuttings; theſe ſhould be planted in ſeptember, upon a ſhady border and in a loamy ſoil; the cuttings ſhould be choſen from the ſhoots of the ſame year, with a ſmall joint of the former year's wood at the bottom of each. Theſe ſhould be planted three or four inches deep, in proportion to their length, treading the ground cloſe to them, to prevent the admiſſion of air. If the following ſpring ſhould prove dry, there ſhould be a little mulch laid over the ſurface of the ground to prevent its drying; where this is performed in time, it will ſave the trouble of watering the cuttings, and it will be much better for them, becauſe when theſe are putting out their young fibres, if they are much watered, it will rot them while they are tender. Theſe cuttings will be rooted enough to tranſplant by the next autumn, when they may be either planted in beds, or in nurſery rows to be trained up.

When they are propagated by layers, the young branches only ſhould be laid down in autumn, or march, which will alſo put out roots by the next autumn, when they may be taken up, and tranſplanted in the ſame manner as thoſe raiſed from cuttings: but although theſe are very expeditious methods of propagating this tree, yet thoſe who are deſirous to have large trees, ſhould always propagate them by ſeeds, for the plants ſo raiſed will be much preferable to the other.

There is a variety of the firſt ſort with variegated leaves, which ſome people keep in their gardens for the ſake of variety; but as this proceeds from a weakneſs in the plants, ſo whenever the plants become ſtrong and vigorous, they always return to their plain colour again, to prevent which they generally plant them in very poor ground. This variety can only be preſerved by propagating the plants either by cuttings or layers.

The China ſort is generally propagated by layers in the ſame way as the former; but the cuttings of this, if rightly managed, will take root very freely; but moſt people have over-nurſed them. If theſe are planted in ſeptember in a border of ſoft loam, expoſed to the eaſt, and before hard froſt ſets in, and the ſurface of the ground covered with old tanners bark about two inches thick, it will prevent the froſt from penetrating the ground very deep; and if this remains in the ſpring, it will alſo keep the ground moiſt; for if theſe cuttings, or the layers of this ſort are watered in the ſpring, when they are beginning to put

[f] Kalm. [g] Boutcher. [h] Hort. kew. [i] Desfontaines & Vahl. [k] Thunb. jap. [l] Travels, 3. 160. engl. ed.

out

Digitized by Google

out young fibres, it will certainly rot them, as I have frequently experienced; therefore I adviſe every one not to water theſe cuttings or layers, nor ſhould the plants be much watered when they are tranſplanted, for the ſame reaſon: but as there are many plants now in England which ripen their ſeeds, ſo thoſe who can be ſupplied with them ſhould prefer this to both the other methods of propagating the plants; for, after the two firſt years, the ſeedling plants will greatly outſtrip the others in growth, and the plants growing with their branches cloſer, will be much handſomer.

Theſe ſeeds ſhould be ſown ſoon after they are ripe, which is in the ſpring. They ſhould be ſown in pots filled with ſoft loamy earth, and plunged into the ground in an eaſt border, where they may have only the morning ſun, obſerving always to keep the pots clean from weeds. Sometimes theſe ſeeds will come up the ſame year, but they often lie in the ground till the next ſpring; therefore the pots ſhould be put in a common hot bed frame in winter, and in the ſpring the plants will come up; theſe muſt not be too much expoſed to the ſun the firſt year, and if in the next winter they are ſheltered under a frame, it will be a good way to preſerve them, and the ſpring following they may be tranſplanted into beds, and treated in the ſame way as thoſe propagated by cuttings.

[The plants raiſed either from cuttings or layers, having got ſufficient roots, tranſplant them to a border ſcreened from the mid-day ſun, in rows two feet and a half aſunder, and one foot in the row; water them at planting, and continue ſo to do once in five or ſix days, when the weather is dry. Here let them remain two years.

Then remove them again, cutting a very little from the ends of the roots. Plant them in rows three feet and a half aſunder, and two feet diſtance in the row; to continue three years, when they will be of a proper ſize to tranſplant where they are to remain. This tree however is as patient of removal large as any evergreen.

The Chineſe Arbor vitæ, is when young, a little more delicate and ſlower of growth than the other, neither does it root well by layers in leſs than two years, or take freely by cuttings in the open ground: it may be adviſeable therefore to ſow ſome of the ſeeds.

If the Chineſe ſort be propagated by layers, the plants muſt ſtand two years to be rooted. The beginning of april plant them in penny-pots, and plunge them in a moderate hot-bed of tanner's bark till the beginning of auguſt; after which inure them to the air by degrees, and place them under ſome protection during the ſucceeding winter. In theſe pots let them remain a ſecond year, when they may be taken out and treated as the common kind. They ſhould be planted, not near, but under the protection of other trees.

The ſort with ſtriped leaves may be increaſed by layers or cuttings, but muſt be planted on thin dry land, to preſerve the variegation ſtrong[m].

THUJA APHYLLA. See *Tamarix articulata.*

THUNBERGIA. (*So named by Retzius, in honour of Charles Peter Thunberg, M. D. knight of the order of Vaſa, profeſſor of botany in the univerſity of Upſal, member of ſeveral learned ſocieties. Author of Travels into Europe, Africa and Aſia; Flora Japonica, &c.*)

Lin. gen. Schreb. n. 1058. *ſuppl.* 46. *Thunb. nov. gen.* 22. *Juſſ.* 103.

Claſſ. 14. 2. Didynamia Angioſpermia.

Nat. order of *Perſonatæ. Acanthi* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* double: *outer* two-leaved; *leaflets* ovate, obtuſe, five-nerved, almoſt the length of the tube: *inner* one-leafed, many-parted; *ſegments* about twelve, awl-ſhaped, three times as ſhort as the outer perianth.

COR. one-petalled, bell-ſhaped: *tube* widening gradually: *border* five-cleft; *ſegments* equal, ovate, very obtuſe, three times as ſhort as the tube.

STAM. *Filaments* four, inſerted into the tube above the baſe, unequal: the two lower ſhorteſt, the two upper ſhorter than the tube. *Anthers* ovate, adnate.

PIST. *Germ* ſuperior. *Style* filiform, a little ſhorter than the tube, erect. *Stigma* two-lobed.

PER. *Capſule* globular, beaked, ſmooth, two-celled, opening longitudinally: *beak* compreſſed, grooved, linear, obtuſe: *partition* obovate, emarginate, perforated below the top, membranaceous at the ſides, permanent.

SEEDS in each cell two, reniform, wrinkled, convex on one ſide, concave on the other with a longitudinal groove.

OBS. *It agrees in many circumſtances with the Barlerias. The leaflets of the exterior calyx are named bractes by Thunberg.*

ESSENTIAL CHARACTER.

Cal. double: outer two-leaved; inner twelve-toothed. *Cor.* bell-ſhaped. *Capſ.* beaked, two-celled.

SPECIES.

1. Thunbergia capenſis.

Lin. ſpec. ed. Willd. 3. 388. *ſuppl.* 292. *Retz. act. lund.* 1. 163. *cum. ic. Thunb. nov. gen.* 1. 21.

Leaves ovate obtuſe, ſtem diffuſed.

2. Thunbergia fragrans.

Lin. ſpec. ed. Willd. 3. 388. *Roxb. corom.* 1. 47. *t.* 67. *Bot. repos. t.* 123.

Leaves cordate acuminate ſomewhat angular-toothed at the baſe, ſtem ſcandent.

DESCRIPTIONS, *&c.*

1. This is a ſingular plant, which nobody would ſuppoſe to be different from the Barlerias, if he did not attend to the double calyx. Stem four-cornered, hirſute. Leaves oppoſite, on very ſhort petioles, quite entire, five-nerved, veined, ſmooth above, beneath hirſute, erect. Peduncles length of the leaves or longer, ſolitary, one-flowered. Bractes two ovate, rough-haired, length of the tube. Calyx enlarging into the fruit. Corolla yellow. Capſule ſmooth, awl-ſhaped, two-parted.—Native of the Cape of Good Hope, where it was found by Thunberg[n].

2. The root conſiſts of many thick woody fibres. Stem and branches twining, woody, of two or three fathoms in extent, jointed and ſwelled from the inſertions of the leaves or their ſcars, round: bark light aſh-coloured: young ſhoots downy. Leaves oppoſite, petioled, three-nerved, ſcabrous, about three inches long, and an inch and half broad: petiole about three quarters of an inch long, channelled, bent in various directions. Stipules none. Peduncle axillary, ſolitary, one-flowered, round, club-ſhaped, downy, one or two inches long. Bractes none. Flowers large of the pureſt white. Leaves of the exterior calyx acute and many-nerved. Corolla ſalver-form: tube compreſſed, enlarged about the middle, a little hairy, longer than the exterior calyx, bent to one ſide with a curve: border flat, five-parted; diviſions equal, obovate, with their extremities truncate, and in general irregularly three-toothed, ſhorter than the tube. Style length of the tube: lobes of the ſtigma obcordate, funnel-form. Capſule ſubglobular, flat-beaked, opening from the baſe with an elaſtic jerk. Seeds in general one in each cell, the other ſeldom or never ripening, round, rugoſe, with a large cavity (as in the Coculi indici) which penetrates two thirds of the ſeed.

This plant is common in hedges, among buſhes, on the banks of water-courſes, about Samulcotah, in the Eaſt Indies. It flowers during the wet and cold ſeaſons: when cultivated it flowers all the year. It poſſeſſes a peculiar and agreeable fragrance; and the beauty of its flowers, though they are not fragrant, entitles it to a place in the flower garden[o].

Willdenow remarks, that it has the appearance of Convolvulus ſepium.

Flowers in heads, leaves linear ciliate:]

DESCRIPTIONS, &c.

1. This is a low ſhrubby plant like Heath, branching out into ſlender woody ſtalks which are ſix or eight inches long, covered with a brown bark, and garniſhed with narrow acute-pointed leaves about half an inch long, ſitting cloſe to the ſtalks oppoſite; they have an aromatic odour when bruiſed. The ſtalks are terminated by thick cloſe ſpikes of purple flowers, near two inches long. The calyxes are ſtiff and hairy; they are cut half their length into acute ſegments, out of theſe the flowers peep, with their two lips; the upper is concave and arched, the under is cut into three equal portions, and theſe are a little reflexed. They appear in june and july, and in warm ſeaſons they are ſometimes ſucceeded by ſeeds which ripen in autumn.

Native of Mount Libanus, Macedonia, Spain, [and the County of Nice.—Cultivated in 1699, by Mr. Jacob Bobart[p]: who had the ſeeds from Aleppo by Dr. Huntington[q].]

2. The ſecond ſort has a ſhrubby ſtalk which ſeldom riſes much more than a foot high, putting out many ſmall woody branches, which have narrow ſpear-ſhaped leaves with many punctures; they ſtand oppoſite, and are of an aromatic flavour. The flowers grow in whorled ſpikes at the end of the branches. The leaves which ſtand under each whorl, are broader than thoſe below, and are covered with fine hairs. The flowers are purple, and ſit cloſe to the ſtalks; the upper lip is concave and ends with two obtuſe points, the lower ends with three equal points. Theſe appear about the ſame time with the other, and in warm ſeaſons the ſeeds ripen in England.

[Stems ſcarcely a foot high. Leaves linear-lanceolate entire dotted. Floral leaves a little wider and ſharper, but ciliate. This is altogether whorled, with ſeſſile flowers: whereas the preceding is indiſtinctly ſpiked; the ſpike oblong, imbricate with bractes or ciliate leaves. Perhaps it may be no more than a variety of the firſt[r].

[p] Hort. kew. [q] Hiſt. oxon. [r] Linn. ſpec.

Native of Spain and Italy. Cultivated in 1702, by the Dutcheſs of Beaufort[s].

3. This is an elegant, upright and very branching ſhrub. The younger branches have a very ſhort down upon them; they are round or ſcarcely four-cornered, ſimple or branched, unequal. Leaves ſtiffiſh, ſpreading, oppoſite, ſeſſile, edged with white hairs, and punctured. Flowers in cloſe, ovate-cylindrical, obtuſe heads. Bractes large, ovate, acute, ciliate, nerved beneath, longer than the calyx: which is round, compreſſed a little, two-lipped; teeth ciliate, the two lower longer, briſtle-ſhaped. Corolla violet: tube ſtraight, twice as long as the calyx: upper lip entire, obtuſe, flattiſh; lower three-lobed, lobes roundiſh, entire. Stamens ſcarcely longer than the corolla. Anthers very ſmall. Stigmas acute.

Native of Barbary, on dry barren hills near Maſcar[t].]

PROPAGATION AND CULTURE.

Sow the ſeeds in the ſpring on a bed of light earth, and the plants will appear in ſix or eight weeks. Keep them clean from weeds, and remove them in july, ſome into ſmall pots, and others into a warm dry border; ſhading them from the ſun, and ſupplying them with water till they have taken new root. If the winter ſhould prove very ſevere, cover the plants in the border with mats or other covering. The pots ſhould be ſheltered under a common frame in winter, where they may enjoy the free air in mild weather, and be protected from froſt. But theſe plants will live in the open air, unleſs in very ſevere winters, eſpecially if they be planted in a poor dry ſtony ſoil.

Heads terminating, ſtem erect, leaves lanceolate.

DESCRIPTIONS, &c.

1. [Root woody, fibrous, brown, perennial. Stems numerous, woody, branched, leafy, pubeſcent, commonly tinged with red: branches alternate. Leaves petioled, elliptic or ovate, obtuſe, quite entire, hollow-dotted with little pellucid glands, ciliate at the baſe and on the petiole with a few fine white hairs; otherwiſe it is commonly ſmooth, though ſometimes hairy all over. Heads of flowers terminating, roundiſh, with little leaves among them. Flowers pedicelled. Calyx ſtriated or ribbed, dotted like the leaves; the two lower teeth deeply gaſhed, narrower, acute, ciliate; the mouth cloſed with white converging villoſe hairs: according to Withering, it is coloured, with a circle of white hairs running round the inſide at the baſe of the ſegments, which, while the plant is in flower, lie flat to the ſides of the calyx, but when the corolla falls off, expand and cloſe up its mouth.—Corolla purpliſh red; the upper lip erect and turning back a little; lower divided into three obtuſe ſegments, the middle one longeſt. Stamens divaricating; the pair inſerted below the upper lip ſhorter than the tube, that below the under lip longer than the tube. Anthers very minute. Style longer than the corolla and turning upwards. Seeds of a brown colour and very ſmall.

Native of Europe, on heaths and dry downs, flowering in july and auguſt.

The whole plant of Wild Thyme is fragrant, and yields an eſſential oil that is very heating. An infuſion of the leaves removes the head-ach occaſioned by a debauch. It has the ſame ſenſible qualities as Garden Thyme, but the flavour is milder, and rather more grateful. Its eſſential oil is both ſmaller in quantity and leſs acrid, and its ſpirituous extract comes greatly ſhort of the penetrating warmth and pungency of the other.

It is a common notion that the fleſh of ſheep, that feed upon aromatic plants, particularly Wild Thyme, is ſuperior in flavour to other mutton. The truth is, that ſheep do not crop theſe aromatic plants, unleſs now and then by accident, or when they are firſt turned on hungry to downs, heaths or commons; but the ſoil and ſituations favorable to aromatic plants, produce a ſhort ſweet paſturage beſt adapted to feeding ſheep, whom nature deſigned for mountains, and not for turnep grounds and rich meadows.

The attachment of bees to this and other aromatic plants is well known.

Few plants are ſubject to more varieties than Wild Thyme. In its moſt natural ſtate, on dry expoſed downs, it is ſmall and procumbent; but when it grows among furze or other plants, it runs up with a ſlender ſtalk to a foot or more in height. It differs alſo very much in the ſmoothneſs or hairineſs of its leaves. The flowers are ſometimes larger than ordinary; and of a paler purple colour, or even white.

The varieties β, γ and η are not uncommon: δ depends principally upon the authority of Petiver, who found it in Okeyhole, Somerſetſhire. According to Miller, if it be his *glaber*] the leaves are broader and ſmoother than thoſe of the common ſort; the ſtalks grow much longer; the joints are farther diſtant, the heads of flowers are larger, and the corolla is of a brighter purple colour. There is a variety of it with variegated leaves, which was formerly planted for edgings

Digitized by Google

edgings to borders, and is frequently brought in pots to the London markets.

ε. Lemon Thyme is frequently kept in gardens, for the agreeable odour of its leaves: when this is propagated by ſeeds, the plants have not the ſame ſcent, it is therefore an accidental variety, which is preſerved by means of ſlips or cuttings. It is found wild in Kent, and at Downton-caſtle, Shropſhire.

ζ. Is known by its narrow ſmooth leaves, ſmelling like thoſe of the Walnut tree. [Dr. Woodville's figure correſponds beſt with this variety.

η. The Hoary Wild Thyme, obſerved by Ray on Gogmagog hills, and the like barren places, ſcarcely differs in any thing from the common except in its hairineſs. The *anguſtifolium hirſutum* of Bauhin is different from this, and is perhaps a diſtinct ſpecies, n. 2.

θ. The ſmall creeping Wild Thyme, without ſcent, was ſent to Plukenet from Ireland, by Bonavert.

ι. The more ſhrubby hairy Mother of Thyme, or Wild Thyme, was found by Lhwyd near Llanberys, and by James Sherard on Snowdon.

Another variety is mentioned by Linneus, with woolly heads, which are the nidus of ſome inſect. This is not uncommon in England. Veronica Chamædrys, Glecoma hederacea, Valeriana Locuſta, and other plants, are frequently diſtorted, from a ſimilar cauſe [u].

The Latin name of *Serpyllum*, and the Greek ερπυλλον, is derived from ερπω, to creep.

2. This, which is conſidered as a variety of the preceding by Linneus, is not changed into that by culture, according to Willdenow. It is a native of Germany and France, on rocks. Miller deſcribes his *lanuginoſus*] as having trailing ſlender ſtalks, with ſmall, ovate-lanceolate, hoary leaves, and the young ſhoots of the ſame year very white and hoary. The leaves are ſtiffer than thoſe of the other ſorts. The flowers, which are in round terminating heads, are of a bright purple colour. According to him, it grows naturally in the foreſt of Fontainbleau.

[3. Stems fruticuloſe, filiform, ſmooth below, villoſe above, aſh-coloured, branched: branches jointed, and forming a ring after the leaves are fallen. Leaves very ſmooth, nerveleſs, hollow-dotted on both ſides, ciliate at the baſe. Head terminating, ſeſſile, hemiſpherical, girt with many leaves of the ſame ſtructure with thoſe on the ſtem but larger. Calyx marked with raiſed hairy lines; teeth awl-ſhaped, ciliate. Corolla ſomewhat hairy. Stamens longer than the corolla [x].—Native of Arabia Felix, on mount Chadra.

4. Garden Thyme is more hoary, higher, harder and more woody than the Serpyllum or Wild Thyme; the leaves are whiter and narrower: and the flowers ſmaller [y].

Native of the South of Europe and Siberia; flowering from may to auguſt.]

Miller makes two ſpecies of the broad-leaved and narrow-leaved Garden Thyme. The latter, he ſays, has ſhorter ſtalks; the leaves are longer, narrower, and end in ſharper points, and the whole plant is hoary; the flowers grow in long whorled ſpikes, and are larger than thoſe of the common (broad-leaved) Thyme.

Tournefort has two other varieties, one very hoary, the other with the heads much ſmaller.

This herb has an agreeable aromatic ſmell, and a warm pungent taſte. The qualities are ſaid by Bergius to be reſolvent, emmenagogue, diuretic, tonic and ſtomachic; but we find no diſeaſe mentioned in which its uſe is recommended either by him or other writers on the Materia Medica. Its aromatic qualities indicate that it may be uſeful in thoſe complaints for which other verticillatæ, as lavender, ſage, roſemary, &c. are employed.—It yields a ſpecies of Camphor in diſtillation with water [z].

Thyme was cultivated in 1596 by Gerarde [a]: and doubtleſs long before; theſe aromatic herbs being ſo much uſed in cookery, before the oriental ſpices were common. In Spain they infuſe it in the pickle with which they preſerve their olives.

5. Stems numerous, branched or ſimple, pubeſcent, roundiſh. Leaves cluſtered, obtuſe, quite entire, petioled, longer than the internodes, nerved underneath, glandular-dotted. Bractes lanceolate, longer than the flower, quite entire. Flowers in whorls, cluſtered into a blunt round ſpike. Calyx round, pubeſcent, ſtriated, dotted; teeth briſtle-ſhaped, ciliate, the two lower ones longer than the other three. Corolla purple, glandular, longer than the calyx, the ſame ſize as in Garden Thyme.

Native of Mount Atlas, about Tlemſen; flowering in ſpring.

6. This is a branching ſhrub: branches ſlender, erect, pubeſcent at the upper part. Leaves quite entire, beneath nerved and dotted. Flowers cluſtered, terminating, in an oblong head. Bractes acute, nerved, length of the flowers. Calyx villoſe, ſtriated, with briſtle-ſhaped teeth. Corolla ſmall, roſe-coloured. It is allied to the next ſpecies, but has the leaves very ſmooth, not ciliate; and the bractes wider at the baſe.—Native of Barbary, near La Calle [b].

7. This has the appearance of common Garden Thyme. Branches many, recurved before flowering. Leaves rolled back longitudinally, pubeſcent above, red underneath. Petioles ciliate. Corolla white [c].—Leaves rugged, thickiſh, dotted. It varies with hairy leaves [d].

Native of Spain. Introduced in 1786, by William Pitcairn, M. D. It flowers in auguſt [e].

8. Stems half a foot high, branched at the baſe, ſeveral from one root, upright, round, pubeſcent towards the top. Leaves oppoſite, eight lines long, and a line and half wide, on very ſhort petioles, attenuated to both ends, ſmooth on both ſides, dotted underneath. Upper floral leaves like thoſe of the ſtem, but ſhorter and three-nerved. Calyxes rough-haired, ſtriated. Corollas longer than the calyx. It varies with leaves narrower by half; is abundantly different from the preceding, and is not even like it in habit. It derives the trivial name from L. B. Marſchall ab Biberſtein, a very ſagacious and indefatigable botaniſt, who found it in Tauria. Pallas took it for the T. Zygis [f].

9. This is a very branching, upright ſhrub: branches approximating: bark on the older branches cloven. Leaves very ſmall, perennial, very cloſe together, ſtiffiſh, nerved beneath, with the margin bent downwards and ciliate. Flowers in whorls, axillary, pedicelled, longer than the leaf, numerous. Calyx ſlender, round, ſtriated; teeth briſtle-ſhaped, ciliate, the two lower ones longer. Corolla purple, longer than the calyx, the ſame ſize as thoſe of T. Serpyllum: upper lip entire, obtuſe; the three lobes of the lower almoſt equal, rounded. Stamens ſhorter than the corolla. Style a little longer than the ſtamens. It has no glands, or very few, and flowers in winter. —Native of dry barren hills near Algiers [g].

10. Root annual, ſimple, fibrous. Stems villoſe, branched, aſcending, about ſix inches high, hairy, purpliſh: branches like the ſtalk, long, ſpreading, the bottom ones oppoſite. Leaves in diſtant pairs, ovate, acute, ſhortly petioled, moſtly ſerrate, the inner middle part next the petiole entire, the outer middle part next the point toothed, the edges turned a little back and ciliate; ſometimes quite entire or having only a ſingle notch on each ſide: they vary to roundiſh or oblong, and the upper ones taper very much at the baſe. Flowers about ſix in a whorl, each on a pedicel various in length. Calyx ſwelling at the baſe on the lower ſide, deeply grooved, the prominent ribs fringed with briſtly hairs: upper lip erect, with three broadiſh nearly equal ſegments; lower projecting in two narrow ſharp ones: mouth fringed with white hairs, which pointing inwards completely cloſe it when

[a] Curtis, Smith, Withering, Lewis, Woodville.

Digitized by Google

the corolla is fallen. Corolla purple: tube dilated upwards: upper lip ſhorter, blunt, turned back, ſlightly notched; lower of three roundiſh ſegments, the middle one longer, obcordate, marked at the baſe with a raiſed white ſemilunar ſpot, and a ſpot or two of darker purple. Anthers ſmall, red. Style the length of the ſtamens. Seeds oblong.

Native of Europe, in dry hilly fields, eſpecially in a calcareous ſoil: flowering in july and auguſt. Not uncommon in England: as about Charlton, Dartford, and other parts of Kent; in Surry and Norfolk not unfrequent; Gogmagog hills and Newmarket heath in Cambridgeſhire; Barton hill and Aſpley in Bedfordſhire; Headington Wick, Stonesfield and South Leigh in Oxfordſhire; on St. Vincent's rocks near Briſtol; on the ſide of Hamilton, Yorkſhire; &c.

It has a pleaſant aromatic ſmell, but commonly much weaker than in T. Serpyllum, to which it bears very little reſemblance: it is much more like T. alpinus, but the flowers of that are nearly twice as large, and the ſwelling at the baſe of the calyx is not ſo conſiderable [h].

11. From a perennial fibrous root, ariſe many ſtems, from a palm to a foot in height, aſcending, pubeſcent, branched. Leaves ovate or lanceolate, acute, ſomewhat villoſe, more or leſs ſerrate above the middle, petioled. The whorls have about ten flowers. Peduncles one-flowered, axillary, ſhort. Calyx ten-ſtreaked, pubeſcent. Corolla pale red [i]: a little larger than that of T. Acinos, according to Desfontaines.

Willdenow remarks, that it is very nearly allied to the next ſpecies.—It ſeems to be biennial, if not annual.

Suppoſed to be a native of the South of Europe and Hungary. Desfontaines found it near Maſcar in Barbary.—Boccone had the plant from the Padua garden; and Jacquin received the ſeeds at various times from ſeveral botaniſts, under Boccone's name.—It was introduced in 1776, by Joſeph Nicholas de Jacquin, M. D. and flowers here from june to auguſt [k].

12. This is allied nearly to T. Acinos, but it is a larger plant, and the flowers are three times as big, peduncled, four on each ſide.

According to Scopoli, the leaves are ovate, toothed here and there above the middle, on villoſe petioles. Peduncles villoſe, two lines long, ſhorter than the calyxes, and theſe ſhorter than the corolla. Calyx ſtriated, hairy, more or leſs violet-coloured. Corolla red; the middle ſegment emarginate.

Villars ſays, it differs from T. Acinos, in having larger, greener and leſs hard leaves; ſtems lower and leſs branched; flowers twice as large, with the calyx coloured not gibbous.

Krocker ſays, that the flowers are three times as big as thoſe of T. Acinos, and redder; the leaves more orbicular, and leſs ſerrate; almoſt indeed quite entire.

Native of the South of France, Auſtria, Carniolia, Switzerland, and Italy.—It was cultivated in 1731, by Mr. Miller [l]: who ſays that he received the ſeeds from Auſtria, Iſtria and Bohemia. It flowers from june to ſeptember.

Villars ſays, it has an aromatic odour, with an agreeable acid, approaching to that of lemon, in which as well as in its characters it approaches nearer to the Calamints and Meliſſa than to Serpyllum. Accordingly Scopoli has united them, and Dr. Smith has united the Calamints to this genus.

13. Stem half a foot high, erect, branched, pubeſcent at the corners. Leaves petioled, blunt, ſmooth, dotted on both ſides, veined beneath. Whorls many-flowered. Calyxes ſtriated, with the three upper teeth oblong, cuſped, ſmooth, and the two lower lanceolate-ſubulate, longer, ciliate.—Native of the Carpathian mountains, the Valais and Piedmont [m].

Allioni ſays, it conſtantly preſerved its hairineſs, the ſize of its leaves, and its peculiar habit, for many years, when cultivated in the Botanic Garden at Turin.

14. Stem almoſt decumbent, round, ſimple or little branched; the firſt branches oppoſite, the reſt alternate. Leaves ſubſeſſile, with the aromatic odour of Serpyllum. The ſtems and branchlets begin to flower about the middle. From each axil iſſues a ſhort peduncle ſupporting three or five flowers, the two lower of which flower later, the middle one earlier, without any bractes, and on a longer peduncle. Calyx ſtriated, cylindrical, the teeth ending in a ſpinule, the three upper ones a little ſhorter. Corolla purple; tube twice as long as the calyx; upper lip erect, cordate, roundly emarginate; lower trifid, the lateral ſegments ovate, the middle one wider, emarginate. Filaments very ſhort: anthers ſemilunar, purple on the inner, white on the outer part. Style ſhorter than the anthers. This plant is nearer to Meliſſa than to Thymus [n].

Dav. Royen remarks, that it reſembles Meliſſa Nepeta, but is ſmooth, and that the leaves are very ſmall.

Vahl ſays, that he has obſerved numerous individuals of this ſpecies, in ſome places ſcarcely a finger's length and decumbent, with the leaves in cluſters, and fewer flowers in the axils; but for the moſt part half a foot high, with many-flowered peduncles. The leaves are always a little thickened at the edge, and the keel is ciliate.—Forſkahl's plant differs from Linneus's only in being ſmaller in all its parts.

Native of Spain, Barbary and Arabia.

15. This is very ſmall and herbaceous. Flowers ſolitary, acute, on a very ſhort peduncle. Upper lip of the corolla ſlightly bifid, erect; middle ſegment of the lower larger, cordate.—Native of Jamaica, in many parts [o].

16. Native of the Balearic iſlands, Majorica, Minorca and Yvica. Introduced in 1770, by Mr. William Malcolm. It flowers in june and july [p].]

17. This has a low woody ſtem, from which come out many ſtiff branches five or ſix inches long. Leaves ſmall, narrow. Heads of flowers pretty large, terminating. Corolla white and very ſmall. The whole plant is hoary, and has a weak aromatic ſcent.

[Stems filiform, purpliſh, with a few ſimple oppoſite flowering-branches at top, ſomewhat villoſe and of an aſh-colour. Leaves ſeſſile, ſpreading, nerveleſs, ciliate at the baſe, a little bent back at the edge, dotted on both ſides: two under the heads linear-lanceolate, a little longer, obſcurely oblique-nerved. Bundles of leaves in all the axils. Heads at the ends of the ſtem and upper branches, ſolitary, the ſize of a hazel nut. Bractes obliquely nerved, membranaceous, purple, acuminate, quite entire, ciliate. Calyxes purple: the upper lip a little wider: teeth briſtle-ſhaped; the two lower ciliate [q].

Native of Spain and Portugal.—Tournefort diſtinguiſhes three varieties: one with very wide bractes; a ſecond with larger heads, and a third with ſmaller heads.

18. This differs from the preceding, in having ſhorter ſtiffer ſtems, not branched at top; wider, upright leaves, ſtriated beneath, ſerrate, dotted only at the edge; the heads ſmaller, cloſely imbricate; the bractes ſtriated, ſmaller, dotted.

Native of the kingdom of Naples, whence it was ſent to Vahl by Cyrillo [r].]

19. This has ſlender, woody, hairy ſtalks, which grow erect about ſix inches high. The lower leaves come out in cluſters, but the upper ones are in pairs. The ſtalks are terminated by ſingle ſcaly heads. The leafy ſcales are indented in acute points, and the purple flowers peep out between them in july; but they do not produce ſeeds in England.—Native of Portugal.

[This and the cephalotus were cultivated by Mr. Miller in 1759.

20. This is an intermediate ſpecies between Satureia and Thymus, but ſince the ſtamens are conceal'ed

[h] Curtis, Engl. bot. [i] Jacqu. obſ. [k] Hort. kew. [l] Idem. [m] Willdenow. [n] Allioni. [o] Browne. [p] Hort. kew. [q] Vahl. [r] Idem.

Digitized by Google

in the bottom of the corolla, and the ſtyle is longer than the corolla, Linneus refers it to this genus. Whorls ſeveral, diſtant. Corollas white, the length of the calyx[s].

It is a ſhrub, a foot in height, or a little more. Leaves heaped on the ſtem, linear or even ovate, the lower hoary beneath, the upper ones ſmooth. Whorls hirſute. Teeth of the calyx hairy and as it were feathered[t].

Native of Spain. Cultivated by Gerarde in 1596[u]. It is omitted in the later editions of Miller's Dictionary.

21. This is a ſweet-ſmelling plant. Stems hirſute, a foot high. Leaves acuminate both ways, and ſtiffiſh.—Native of the iſland of Candia or Crete[x].]

22. Root perennial; but the ſtalk annual, riſing about a foot and half high, ſtiff, angular, branching out towards the top. Leaves ſtiff, pointed, about an inch and half long, and a quarter of an inch broad in the middle, pointed at both ends, and having a ſtrong ſcent of Pennyroyal. Flowers white, collected into globular heads. They appear in july; but the ſeeds ſeldom ripen in England.—Native of North America.

[It was cultivated in 1739, by Mr. Miller[y].]

PROPAGATION AND CULTURE.

1. The common Mother of Thyme or Wild Thyme, is very frequent on dry paſtures, and is very rarely admitted into gardens. This plant may be propagated either by ſeeds or parting the roots; the ſeaſon for either is in march or october. If it is propagated by ſeeds, they ſhould be ſown upon a bed of light earth, obſerving not to bury the ſeeds too deep, which will cauſe them to rot, nor to ſow them too thick, for the ſeeds are very ſmall. When the plants are come up, they ſhould be carefully cleared from weeds; and if the ſpring ſhould prove dry, and they are watered twice a week, it will greatly promote their growth. In june the plants ſhould be thinned, leaving them about ſix inches aſunder each way, that they may have room to ſpread; and thoſe plants which are drawn out may be tranſplanted into freſh beds at the ſame diſtance, obſerving to water them until they have taken root; after which they will require no farther care but to keep them clear from weeds, and the winter following they may be drawn up for uſe.

But if the plants are propagated by parting their roots, the old plants ſhould be taken up at the times before mentioned, and ſlipped into as many parts as can be taken off the root; theſe ſhould be tranſplanted into beds of freſh light earth, at ſix or eight inches diſtance, obſerving, if the ſeaſon is dry, to water them until they have taken root, after which they muſt be duly weeded, and they will thrive, and ſoon be fit for uſe.

In order to ſave the ſeeds of theſe plants, ſome of the old roots ſhould remain unremoved in the place where they were ſown the preceding year; theſe will flower in june, and in july the ſeeds will ripen, which muſt be taken as ſoon as ripe, and beat out, otherwiſe the firſt rain will waſh it all out of the huſks.

Theſe plants root greatly in the ground, and thereby draw out the goodneſs of the ſoil ſooner than moſt other plants; ſo that whatever is ſown or planted upon a ſpot of ground whereon Thyme grew the preceding year, will ſeldom thrive, unleſs the ground be trenched deeper than the Thyme rooted, and well dunged.

If this plant grows upon walls, or on dry, poor, ſtony land, it will endure the greateſt cold of this country; but in rich ground where the plants grow vigorouſly, they are ſometimes deſtroyed by ſevere froſt.

There is a variety of this with variegated leaves, which is by ſome preſerved in their gardens.

7. 16. 17. 19. 20. Theſe may be increaſed by ſlips, planted in april, on an eaſt border, and cloſely covered with a bell or hand-glaſs, refreſhing them twice a week with water, in a moderate quantity. When they have put out good roots, tranſplant ſome into pots, to be ſheltered under a frame in winter, and plant the reſt on a warm border of dry ground, obſerving to ſhade and water them till they have taken new root: in ſevere froſt, the latter will generally be deſtroyed. They may alſo be propagated by ſeeds, ſown on a bed of light earth, in the ſame way as common Marjoram.

Moſt of the other ſorts may be increaſed by ſlips or parting the roots. Or the ſeeds may be ſown in the ſpring. They delight in dry undunged ground, where ſome of them will increaſe by their trailing ſtalks.

DESCRIPTIONS, *&c.*

1. This has a perennial fibrous root, which creeps. Leaves of a light green colour, unequally indented on their edges, on ſlender foot-ſtalks, three inches long, ariſing immediately from the root. Flower-ſtalks ſlender, naked, about four inches long, ariſing alſo from the root between the leaves, and terminated by a looſe ſpike of ſmall herbaceous white flowers, which appear in may, but are ſeldom followed by ſeeds in England. Native of North America, [and the northern part of Aſia.

Retzius has a ſpecies (*obſ.* 3. 30. *n.* 48.) which he names *unifolia*, from its having a ſingle leaf upon the ſtem. All the leaves are cordate. It is much ſmaller than the *cordifolia*; the leaves are not lobed, the ſcape is few-flowered, and the ſingle leaf on it is almoſt ſeſſile.

In *cordifolia* the ſcape is quite naked; and the leaves are duſky, ſublobed, and have the notches more frequent.—*T. unifolia* is a native of Newfoundland.]

2. This alſo has a perennial fibrous root, from which ſpring up a few trifoliate petioled leaves, like thoſe of the Bilberry, but much ſmaller. The ſtalk is ſlender, and riſes five or ſix inches high; it is rough and hairy, has two leaves at the bottom, and one towards the top, a little below the ſpike of flowers; they are angular and ſerrate. The ſtalk is terminated by a looſe ſpike of white flowers, which appear early in may; but the plants rarely produce any ſeeds in England. Native of the northern parts of Aſia. Both the ſorts were cultivated by Mr. Miller in 1759.

DESCRIPTIONS, *&c.*

1. The Lime or Linden is a tall upright tree, with ſmooth ſpreading branches, thickly clothed with alternate, petioled, heart-ſhaped, ſmooth, ſerrate leaves, pointed at the end, oblique at the baſe, glaucous beneath, and the veins, where they branch off from the nerve, being furniſhed with a tuft of glandular wool, as in the Laurus-tinus. The flowers, which are delightfully fragrant, eſpecially at night, come forth in july, in umbels or cymes, (from three to five together,) on long axillary peduncles, with a ſingular oblong, blunt, membranaceous, pale, entire bracte, nearly as long as the peduncle, and attached to it for about half its length, and falling off with it. Calyx green with a downy edge. Petals yellowiſh, obtuſe, concave. Stamens filiform. Stigma five-cleft. Germ villoſe, depreſſed. Capſule ſmooth, with from four to eight unequal angles: commonly one-celled and one-ſeeded, ſpongy within, with moſt of the cells abortive. Seed roundiſh *.

Gærtner deſcribes the capſule as coriaceous, ſubturbinate or ovate-globular, terminated by a long permanent ſtyle, indiſtinctly angular with five filiform ribs, of a duſky or ſmoky colour, pubeſcent, five-celled, valveleſs: partitions membranaceous, very thin, white, obverſe to the ribs. Receptacle none: but two ovaries one above the other faſtened to the central angle of the cells. Seeds ſolitary, or ſometimes, but very ſeldom, two in a cell, but it rarely happens that more than one ripens: ſhape ovate-acuminate, convex on one ſide, on the other obſcurely angular, marked on the middle of the belly with an oblong umbilical ſcar, and having a ſmall excavation at the vertex; it is ſmooth and of a pale reddiſh brown colour.

Gærtner could not obſerve that the capſules ever open ſpontaneouſly from the baſe, as Linneus affirms they do, nor could he even diſcover any veſtiges of ſutures, he therefore ſuſpects that they burſt rather than ſeparate regularly.

It is remarkable that the cotyledons of the Lime tree are ſubtrilobate and toothed; and it is peculiar to it, as far as we know, that theſe are already toothed whilſt they are lying within the coats of the ſeed *.

* Smith brit. & engl. bot. * Gærtner.

Native

Digitized by Google

Native of Europe, and according to Thunberg of Japan.—The ſmall-leaved variety is truly wild in many parts of England, in woods and on graſſy declivities: the common broad-leaved and other varieties are more commonly ſeen cultivated in hedges, avenues, parks and before houſes. It will in ſome degree bear the ſmoke of London[b]. The Lime-trees in St. James's park are ſaid to have been planted at the ſuggeſtion of Mr. Evelyn[c]. Probably with a view to the improvement of the air, and to avert, in part, the evils pointed out in his Fumifugium. The Dutch plant this tree very much by the ſide of their canals. The whole country is perfumed by the flowers during the months of july and auguſt; when the ſtagnant water of the canals in many parts would otherwiſe be very diſagreeable at that ſeaſon. As an ornamental tree it is common in Germany, Switzerland, &c. And in England it was formerly much more cultivated than it is at preſent.] Of late years, ſays Mr. Miller, the Lime tree has been little eſteemed, becauſe it is late in the ſpring before the leaves come out, and they begin to decay firſt in autumn; and when it is planted in a dry ſoil, the leaves frequently fall off in july, and continue to make a litter all the remaining part of the ſummer.

[It was highly eſteemed by the Romans for its ſhade, and the numerous uſes for which it ſerved: "Tiliæ ad mille uſus petendæ."

Mr. Evelyn ſpeaks of it, as "a ſhameful negligence, that we are no better provided of nurſeries, for a tree ſo choice, and univerſally acceptable: for in his time they ſent into Holland and Flanders, to our exceſſive coſt, whilſt our own woods ſpontaneouſly produce them, and though of ſomewhat a ſmaller leaf, yet altogether as good, apt to be civilized, and made more florid."

However the Lime tree may be now gone out of faſhion, it is certainly a handſome tree, having a ſmooth taper ſtraight trunk, and the branches forming a beautiful cone. The foliage alſo is ſmooth and elegant. It will grow to a very large ſize, and the ſhade being reputed excellent, it was proper for avenues, when they were in requeſt. It makes a fine detached object in parks and open lawns, planted ſingly. The branches are ſo tough as ſeldom to be broken by the winds; and if they are, no tree heals its wounds ſooner. To all this we may add the fragrancy of the flowers, which are continually haunted by bees[d].

Lime-tree wood is turned into light bowls and diſhes, and into boxes for the apothecaries. With the twigs they make baſkets and cradles. Formerly the bark was uſed for writing tablets. Shoemakers make dreſſers of the plank to cut leather on. The truncheons make a far better coal for gunpowder than that of Alder itſelf; and alſo ſcriblets for painters firſt draughts. The wood is ſoft, light and ſmooth, cloſe grained and not ſubject to the worm. The moſt elegant uſe to which it is applied, is for carving. Many of Gibbons's beautiful works in Lime-tree are diſperſed about the kingdom, in our churches and palaces; as in the choir of St. Paul's, the Duke of Devonſhire's at Chatſworth, Trinity College Library at Cambridge, &c.—Mr. Evelyn firſt recommended him to King Charles the Second[e]. The ſap inſpiſſated affords a quantity of ſugar.

Mr. Boutcher remarks, that the timber is ſtronger and lighter than any ſort of Willow; and makes a proper lining for rooms, which when painted will laſt long.]

The Lime-tree will continue growing, and remain ſound a great number of years: in a good loamy ſoil, it will alſo grow to a conſiderable bulk. One of theſe trees was near ten yards in girth two feet above the ground, and was then in a thriving condition. Sir Thomas Brown mentions one of theſe trees which grew at Depeham in Norfolk, that was ſixteen yards in circuit, about half a yard high, almoſt twelve yards near the ground, and in the leaſt part of the trunk eight yards and a half; it was thirty yards in height.

[A Lime-tree is deſcribed by Dr. Turner as growing in a park near Colcheſter; it muſt therefore have been cultivated in England before 1562.

There are or were ſeveral very large trees of this kind in Switzerland: as one near Morges twenty-four feet four inches in circumference; another near the great church at Berne, thirty-ſix feet in girth, planted before 1410; the hollow trunk of which exiſted in 1720; and a third near Morat, at leaſt thirty-ſix feet round, and not leſs than ninety feet high, it was lopped in 1550, and is now, or was lately ſtanding[f].

Mr. Evelyn gives an account of ſeveral enormous Lime-trees in Switzerland, Germany and Hungary[g].

The Italians and French have followed the Latin name in *Tiglio* and *Tilleul*: we have adopted the German Linden, in our *Lime*, or as it is in Gerarde *Line-tree.*

In Lincolnſhire, as Mr. Ray was informed by Dr. Martin Liſter, it is called *Baſt*, becauſe they make ropes of the bark.—This, by maceration, ſeparates into thin tough layers, and is uſed for making the mats uſed by gardeners, and called in the north of Europe *Baſt*. They form a conſiderable part of the exports from Ruſſia. This quality in the bark, and a great degree of viſcidity in the whole tree, evince its acknowledged affinity to the Mallow tribe[h].

Mr. Miller makes two ſpecies of our European Lime tree, the *cordata*, which is the ſmall-leaved one, wild in England, and the *europæa*, to which he gives Ray's ſynonym of the red-twigged Lime tree.] Of the firſt, he ſays, there are two or three varieties, which differ in the ſize and ſmoothneſs of the leaves, ſome having much larger and rougher leaves than others; but they vary from one to the other, when raiſed from ſeed, and it is even doubtful whether the ſecond (europæa) be more than a ſeminal variety. The large-leaved Dutch Lime (maxima β.) was generally preferred to our common ſort, for the ſize of its leaves.

[Scopoli alſo, following Haller, diſtinguiſhes the large-leaved and ſmall-leaved varieties. The former, he ſays, not only has the leaves larger, but ſofter and ſomewhat hairy or villoſe; in the latter they are harder, and no where villoſe: this likewiſe flowers two or three weeks later.

δ. Was obſerved by Merret at Whitſtable and near Darking in Surry.—The Red Lime ε was found growing naturally in Stokenchurch-wood, by Bobart, and lately by Sibthorp.

In Ray's ſynopſis (ed. 3.) three varieties are remarked in St. James's-park. 1. The ſmooth ſmall-leaved. 2. The ſmooth large-leaved. 3. The ſoftly hairy-leaved. 4. There is a fourth with wrinkled leaves not hairy; of which Mr. Doody obſerved ſeveral trees on Enfield-green going to the Chaſe.

Beſides all theſe, there is a variety with ſtriped leaves.]

2. This was brought from New England by the name of Black Lime; the branches being covered with a dark brown bark. The leaves are large, heart-ſhaped, end in acute points, are deeply ſerrate, and of a full green on their upper ſide, but of a pale green and a little hairy on their under ſide; ſtanding upon long ſlender foot-ſtalks. The petals are narrower, and have nectariums growing to their baſe. The flowers do not appear till late in july, a full month after the common ſort. The capſules are ſmaller, rounder, and leſs hairy than in that.

[Native of Virginia and Canada. Cultivated in 1752 by Mr. Miller[i].]

3. This tree ſeems to be of much ſmaller growth than either of the former; the branches ſpread more horizontally; the leaves are ſmaller, and have a ſmoother ſurface, they are heart-ſhaped but the mid-rib runs obliquely to the foot-ſtalk, ſo that one ſide of the leaf is much larger than the other, the edges are ſlightly ſerrate and their ends run out into long acute

points.

points. The bunches of flowers ſtand upon long ſlender foot-ſtalks; the petals are narrow, and end in acute points; they have each a narrow nectarium faſtened to their baſe on the inſide ſtanding erect cloſe to the petals: The flowers emit a very fragrant odour, and are continually haunted by bees during their continuance: they come out towards the end of july, and when the ſeaſon proves favourable, the ſeeds ripen in autumn.

The ſeeds were brought from Carolina by Mr. Cateſby: [it was therefore introduced about the year 1726 [k].

4. The leaves are ſnow-white beneath. The flowers as in *T. americana*, but ſmaller. In the *hortus kewenſis* it is ſaid to be a native of North America, but no authority is given; and Kitaibel having lately diſcovered woods of this ſpecies in Hungary, its ſuppoſed American origin muſt be conſidered as doubtful [l].

It was cultivated in 1767, by Mr. James Gordon [m].]

PROPAGATION AND CULTURE.

All theſe trees are eaſily propagated by layers, which in one year will take good root, and may then be taken off, and planted in a nurſery, at four feet diſtance row from row, and two feet aſunder in the rows. The beſt time to lay them down and to remove them, is at michaelmas, or ſoon after, when their leaves begin to fall, that they may take root before the froſt comes on, though they may be laid and tranſplanted any time from ſeptember to march, in open weather; but if the ſoil is dry, it is much the better way to remove them in autumn, becauſe it will ſave a great expence in watering them, eſpecially if the ſpring ſhould prove dry. In this nurſery they may remain four or five years, during which time the ground ſhould be dug every ſpring, and conſtantly kept clear from weeds, and the large ſide ſhoots pruned off, to cauſe them to advance in height; but the ſmall twigs muſt not be pruned off from the ſtems, becauſe theſe are abſolutely neceſſary to detain the ſap, for the augmentation of their trunks, which are apt to ſhoot up too ſlender, when they are entirely diveſted of all their lateral twigs. If the ſoil in which they are planted be a fat loam, they will make a prodigious progreſs in their growth, ſo that in three years time they will be fit to tranſplant out where they are to remain.

They may alſo be propagated by cuttings, but, as this method is not ſo certain as by layers, that method is generally practiſed. In order to obtain proper ſhoots for laying down, a Lime-tree is cut down cloſe to the ground, from the roots of which a great number of ſtrong ſhoots are produced the following year; theſe will be ſtrong enough to lay down the following autumn, eſpecially if the ſmalleſt of them are cut off cloſe early in the ſummer; for when too many ſhoots are ſuffered to grow all the ſummer, they will be much weaker, than if only a ſufficient quantity is left. See LAYING.

There are ſome perſons who raiſe theſe trees from ſeeds, which, although it is a ſlower way, yet when the trees are deſigned to grow large, is the beſt method; and if they are only once tranſplanted, and this performed while they are young, it will be ſtill the better way; for all trees that are tranſplanted when large, are ſhorter lived than thoſe which remain in the places where they aroſe from ſeeds, and their timber will be ſounder, and grow to a much larger ſize.

When this method is practiſed, the ſeeds ſhould be ſown in autumn ſoon after they are ripe, upon a ſhady border of moiſt light ſoil, where the plants will come up the following ſpring; but, when the ſeeds are kept out of the ground till ſpring, the plants will not come up till the year after. When they appear, keep them clean from weeds till the following autumn, and then carefully take them up and tranſplant them into a nurſery, where they may grow two or three years to get ſtrength, and then may be planted where they are deſigned to remain.

[Mr. Boutcher recommends the ſeeds to be gathered at the end of october, when they are ripe, and after being quite dry, to mix them with ſand, to protect them from froſt and rain, and to ſow them the beginning of march.

Dr. Hunter directs the ſeeds to be ſown in beds three feet and a half or four feet wide, about an inch aſunder, covering them three quarters of an inch or an inch deep. They will appear in the ſpring; during ſummer they muſt be weeded, and in very dry weather watered a little: before winter ſift ſome aſhes over them to deſtroy the moſs. In two years they will be fit to plant out in the nurſery, in rows two feet and a half aſunder, and each tree at eighteen inches diſtance, ſhortening the roots a little, and cutting off any ſide branches. They will bear removing at any ſize.

If they are wanted to remove large, ſays Mr. Boutcher, they muſt be removed again and again every four years. At eleven years old they will be twenty feet high, and at ſixteen years old, from thirty to thirty-five. This may do for a few trees deſtined to ſome particular purpoſe; but for utility they can hardly be finally tranſplanted too young.

In taking up layers, Mr. Boutcher directs the roots to be moderately ſhortened, and ſuch as croſs each other to be cut away. If the layer be well rooted and thick in proportion to its height, plant it at full length of a foot or ſix inches, according to its ſize and quantity of roots. Plant theſe layers in rows three feet aſunder, and at fifteen inches diſtance in the row.

The Lime-tree will grow in almoſt any ſoil and ſituation; but in thin ſoils the leaves are often infeſted with inſects, and fall early in autumn, eſpecially in dry ſeaſons.

Stems procumbent, flowers ſeſſile moſtly trifid.

DESCRIPTIONS, *&c.*

1. This is a ſmall plant, and annual, as indeed all the ſpecies are. The flowers are commonly four-cleft and four-ſtamened.

Native of Lapland; and very abundant near Upſal, where water ſtagnates on the mountains [n].

2. Native of Germany, in moiſt places.

3. Linneus has given Vaillant's name to the firſt ſpecies, but it is very diſtinct from that in the form of the leaves, and in its long-peduncled flower.—Native of France, in moiſt places [o].

4. Roots capillary, abundant, ſtem an inch high, herbaceous, dichotomous. Leaves oppoſite, ſomewhat fleſhy. Flowers peduncled, ſolitary. Calyx four-parted, ſpreading, with oval leaflets. Petals four, oval, white, twice as long as the calyx. Nectaries purple, triangular.

Native of the Cape of Good Hope [p]. In the Supplement of the younger Linneus this is ſuppoſed to be a mere variety of T. aquatica.

5. 6. 7. Theſe are alſo natives of the Cape, and all found there by Thunberg, who unites them with the Craſſulas; from which they differ, as Sedum does from Sempervivum [q].

It is remarked in the Supplementum Plantarum, that there is a great affinity between this genus and Craſſula, and that ſcarcely any difference is to be found between them except in the number of parts. Gærtner obſerves, that this difference is of little avail in the *Succulentæ*; and that Tillæa differs from Craſſula only in the want of a nectary.

Tillæa decumbens (n. 7.) is a diſtinct plant from Craſſula decumbens.

8. Root annual, ſmall, fibrous. Herb ſucculent, ſmooth, generally red. Stems numerous, filiform, round (becoming quadrangular when dry,) jointed, one or two inches high, but lengthening conſiderably after flowering, at firſt nearly erect but after a while procumbent. Leaves ſtrictly perfoliate, very fleſhy, obtuſe, gibbous, oppoſite, ſometimes three together, concave above, convex beneath, ſometimes as long as the internodes, and ſometimes only half as long. Flowers one or two together in the boſoms of the leaves, nearly ſeſſile, and ſometimes accompanied with a pair of ſmaller leaves, which Mr. Roſe calls bractes. Calyx of three ſtill ſmaller leaves, diſtinguiſhable by their ſharp points. Petals three, ovate, or awl-ſhaped, acute, pellucid, leſs than the calyx. The flowers are ſometimes four-cleft, and even, according to Gærtner, five-cleft. Stamens and ſtyles ſtill ſhorter. Capſules three, ovate, two ſeeded [r]. —They are thus deſcribed by Gærtner. Capſules three, or five in the cultivated plant, oblong, acuminate, erect, knobbed a little where the ſeeds are, one-celled, opening lengthwiſe inwardly. Seeds two, very ſmall, ovate, ſmooth, ferruginous, faſtened to the opening future.

Native of Italy, Sicily, France and England, in dry, barren, ſandy and gravelly ſoil; flowering from the end of may to october.

The moſt dreary ſands are not always unprofitable to a botaniſt. Their looſe and fluctuating ſurface being often arreſted for a while, and deſtined to afford ſupport to a tribe of plants, the conſtitution of which is fitted by the all-wiſe Creator to thrive beſt on the meagre nouriſhment they afford. Thus ſome of the vaſt African deſerts are turned to account by means of Meſembryanthemums, Cotyledons, and other ſucculent vegetables. We have here a production nearly allied to the Cotyledons, which flouriſhes on the drieſt ſandy heaths, where few others would live, and at a ſeaſon when Moſſes and Lichens are dried up. Large tracts of the above deſcription in Norfolk, as Drayton, Cawſton and Mouſhold heaths, as well as Brandon heath in Suffolk, are enlivened by its red colour. Sir Thomas Gery Cullum found it alſo near Bury. Mr. Roſe ſays, it was firſt determined (in England) by the Rev[d]. Mr. Bryant in 1766.

Although this plant is commonly triandrous, yet as the other ſpecies of Tillæa have four ſtamens, it muſt continue with them in the fourth claſs, where Linneus has placed them [s].

DESCRIPTIONS, *&c.*

1. Many brown fibrils encompaſs the arms, or take firm hold on the bark of the trunk of trees, not as Miſleto, entering the bark or wood to ſuck nouriſhment, but only weaving and matting themſelves among one another, and thereby making to the plant a firm and ſtrong foundation, whence riſe ſeveral leaves on every ſide, like thoſe of Aloes or Ananas, which has given occaſion to its name of Wild Pine; they are folded or incloſed one within another, each three feet and a half long, and three inches broad at the baſe, but ending in a point, having a very hollow or concave inward ſide, and a round or convex outward one, forming a baſon or ciſtern, containing about a quart of water, which in the rainy ſeaſon falls upon the upper parts of the ſpreading leaves, and being conveyed down them by channels, lodges in the bottom as in a bottle; for the leaves having ſwelled out at the baſe, bend inwards cloſe to the ſtalk, thus hindering the evaporation of the water by the heat of the ſun. From the midſt of the leaves riſes a round ſmooth ſtraight green ſtalk, three or four feet high, having many branches, and when wounded yielding a clear white mucilaginous gum. The flowers come out here and there on the branches. The corolla is of a yellowiſh white or herbaceous colour; and the calyx is made up of three green viſcid leaves with purple edges. Capſule greeniſh-brown, having under it three ſhort capſular leaves, and within ſeveral long pappoſe ſeeds, which are oblong-pyramidal and very ſmall, have a very ſoft down, as long as the capſule itſelf. By this down the ſeed is not only carried with the wind, but it is enabled by it to ſtick faſt in the bark of trees. As ſoon as it ſprouts, although it be on the under part of a bough, it riſes perpendicularly; for if it had any other poſition, the ciſtern could not hold the water which is neceſſary for the life and nouriſhment of the plant.

In the mountainous as well as dry low woods, this reſervatory is very uſeful to men, birds and inſects, who in ſcarcity of water frequent theſe plants in troops.

Dampier ſays he has many times to his great relief ſtuck his knife into the leaves juſt above the roots, and let out the water into his hat.

Native of South America. In Jamaica it is found every where in the woods, eſpecially on decaying trees, which in time it diſſolves [t].

2. This alſo is a native of South America, and common in Jamaica, where it is called Wild Pine, with all the other ſorts. Browne names it the largeſt Tillandſia or Wild Pine, with a variegated flower-ſpike.

3. This grows on large trees, to which it faſtens itſelf by many long dark brown threads, making all together an oblong root. Culm leafy, ſimple, erect, ſolitary, bearing conglomerate flowers at the top. The radical leaves are linear-tongue-ſhaped, acuminate, ſhining, quite entire, a foot long, numerous, containing water like the firſt ſpecies. Flowers yellow, inodorous, three inches long. Capſules brown [u].

Native of South America, Jamaica and Martinico, where it is called *Ananas de Bois*, or wood Pine-Apple.—Cultivated in 1776, by Mr. James Gordon [x].

4. Stem a foot high, ſimple, ſheathed, leafy. Leaves often the length of the ſtem; the radical and lower ones ſheathed at the baſe, above the baſe attenuated, keeled, convolute, rigid. Stem-leaves or ſheaths cloſely ſurrounding the ſtem, terminated by a very long linear-filiform apex. Spikes three or four, terminating, ſeſſile, ſubdiſtich, an inch long, lanceolate. Spathes oblong, obtuſe. Petals blue.—Native of South America and the Antilles, on trees.

5. Roots filiform, long, rigid. Leaves moſtly radical,

[t] Sloane. [u] Jacquin. [x] Hort. kew.

Digitized by Google

ſical, wider at the baſe, ſeſſile, ventricoſe, embracing, entire, looſe, ſtriated, membranaceous, beneath whitiſh, ſubtomentoſe or mealy with very minute ſcales which are peltate and hollowed in the middle, ſurrounded by a hyaline ſtriated margin, not to be diſtinguiſhed without a magnifying glaſs. Stem or ſcape longer than the leaves, two or three feet high, looſe, round, with alternate, lanceolate, acute, red ſheaths; the lower ending in linear leaves; ſubdivided at the top, and terminated by two or three ſpikes, which are ſolitary, long, looſe, with a flexuoſe three-ſided rachis, and alternate, diſtich, remotiſh florets. Bractes or ſpathes one-leafed, lanceolate, concave ſtriated. Calyx three-parted, three-cornered at the baſe: ſegments erect, coloured. Petals three, linear, longer than the calyx, turned back at the tip, ſcarlet or blue. Filaments alternately a little ſhorter, inſerted into the receptacle, filiform, almoſt the length of the petals. Anthers ovate, bifid at the baſe, whitiſh. Germ ovate, three-cornered, three-keeled, three-celled, three-valved, within ſhining and black. Seeds crowned with a capillary yellowiſh down.

On the branches of old trees near the coaſt in Jamaica, and near Carthagena in New Spain.

6. This reſembles T. tenuifolia, but is quite diſtinct in having the leaves reclined, and the ſpike ſimple; whereas in that the leaves are erect, the ſpikes many and alternate.

Stem a foot high and more, round, almoſt upright, covered from the root up to the ſpike with alternate, ſubimbricate ſheaths, broad-ovate at the baſe, and at the end attenuated into linear-ſetaceous leaves. Radical leaves almoſt the length of the ſtem, ſheathing, imbricate, numerous, ſomewhat mealy with very minute ſcales, aſh-coloured, rigid. Sheaths ſmall, or only the baſe of the leaf widened. Spike terminating, undivided, ovate-lanceolate, with alternate, diſtich flowers: ſpathes wide-ovate, acuminate, membranaceous, ſubcoriaceous, equitant. Capſule ovate, acuminate.—Native of Jamaica on trees[y].

7. Native of South America and Jamaica. Browne calls it the looſe-headed Tillandſia or Wild Pine.

8. Roots filiform, rigid. Stem ſimple, from one to two feet high, leafy. Leaves next the root ſheathing at the baſe, broad, concave, towards the end lanceolate, convolute-ſubulate, upright and ſtraight or a little recurved at the tip, pubeſcent on the outſide: ſtem-leaves ſhorter, ſubimbricate, ovate, ending in a long awl-ſhaped point. Spikes terminating and lateral, erect, alternate, ancipital, an inch wide, imbricate in two rows with bractes or ſpathes, which are called glumes by Linneus, equitant, ovate-acuminate, membranaceous at the edge, ſmooth. Rachis three-ſided. Flowers ſolitary, ſeſſile between the ſpathes. Calyx tubular, three-cornered, or two-keeled at the back, three-parted at the end: after the flower increaſes, it ſurrounds the capſule with two leaves, the ſuperior bifid and two-keeled, the inferior lanceolate and convex. Capſule oblong, acuminate, an inch long, three-cornered, three-celled, three-valved: valves rigid, black within. Seed-down capillary, ſilky.—T. polyſtachya is diſtinct from this, in having the ſpikes ſcattered, (not diſtich) and narrower; leaves reclined not erect.—Native of Jamaica, on trees, near the coaſt.

9. Plant from one to two feet high. All the leaves radical, entire, ventricoſe at the baſe, ſtriated longitudinally, marked with lines, ſmooth, half a foot long. Scape ſheathed, jointed, round, looſe, ſmooth. Sheaths alternate, approximating, ovate-lanceolate, acuminate, ſtriated, ſmooth, membranaceous. Spikes terminating, alternate, ſomewhat remote: rachis angular: flowers ovate, ſcattered, diſtinct, approximating, but not imbricate. Bractes or ſpathes ovate, obtuſe, concave, membranaceous, rigid, ſolitary, incloſing the florets. Calyx three-leaved: leaflets ovate-lanceolate. Petals three ovate-lanceolate, erect, ſhrivelling, white. Filaments awl-ſhaped, from the baſe of the petals, and of the ſame length with them, erect. Anthers ovate, bifid at the baſe, ſubſagittate. Germ three-cornered, acuminate, ſmooth. Style ſhort, three-cornered. Stigmas three, ſimple. Capſule roundiſh-ovate, acuminate, three-cornered, three-keeled, three-celled, three-valved: valves black and ſhining within. Seed-down very long, white ſhining and ſilky.—Native of Jamaica, on the branches of trees in the mountains[z].

10. Native of South America.—See n. 13. 14.

11. Native of South America and Jamaica. Browne calls it the larger Tillandſia with obtuſe leaves.

12. Plant from two to three inches high. Rootlets filiform ſimple rigid curled. Stem very ſhort, leafy. Radical leaves ſheathing at the baſe; ſheaths wide, ovate, ventricoſe, membranaceous, ſtriated: the edges of the leaves are convolute; they are bent different ways; and are tomentoſe with very numerous ſcales, which are ſubimbricate, (not preſſed cloſe,) torn, whitiſh, glittering like hoar froſt. Stem-leaves ſheathed, imbricate, equal to the radical leaves and like them, with embracing ſheaths, not ventricoſe at the baſe. Spike terminating, an inch long, ovate, acute: flowers ſubdiſtich: ſpathes ovate, acuminate, ſcaly-tomentoſe all over. Petals longer than the ſpathes, blue. Capſule oblong, acuminate, three-ſided, ſmooth.—This is not to be confounded with T. recurvata, which has linear-ſubulate leaves, radical peduncles, and two-flowered ſpathes.—Native of Jamaica, on old boughs of trees.

13. Plant about a foot high. Radicles ſhort, ſimple, filiform, curled, brown. Stem ſheathed, leafy, undivided. Radical leaves ſheathed at the baſe, imbricate, whitiſh, rigid. Sheaths very wide, ovate, concave, ventricoſe, membranaceous. Stem-leaves ſheathed looſely, and linear-acute. Spikes terminating, for the moſt part in threes, approximating, ſeſſile, ovate, acute, compreſſed a little, ſubdiſtich: flowers diſtich: ſpathes ovate-lanceolate, imbricate, equitant, ſmooth. Petals long, red. Capſule oblong, acuminate, three-cornered, involved in a ſpathe.—This is different from T. polyſtachya, to which it is near allied: the ſtem in that is higher; the leaves are reclined, flexuoſe and ſmooth; the ſpikes many, lanceolate and ſcattered.—Native of Jamaica, on trees near the coaſt.

14. Plant two feet high. Stem almoſt upright, ſimple, ſheathed, leafy. Radical and ſtem-leaves imbricate, wide and ſheathing at the baſe, lanceolate above and linear at the end, ſtriated, longer than the whole plant, ſtiff and ſtraight. Radical ſheaths wider, ſubventricoſe. Spikes very many, alternate, ſeparated by leafy ſheaths, ſubimbricate, compreſſed, lanceolate, an inch and half long, many-flowered. Flowers diſtich: ſpathes imbricate, equitant, ovate, acuminate, keeled, ſtriated, ſmooth. Capſules elongated, acuminate, three-ſided, ſmooth, longer than the ſpathes.—Diſtinct from T. polyſtachya, in having the leaves longer than the ſtem, and more erect; the ſpikes ſeparated by leafy ſheaths.—Native of Jamaica and Hiſpaniola, on the trunks and branches of trees[a].

15. Roots filiform, cluſtered, whitiſh. Stems aggregate, ſimple; or leaves conſtituting the ſtem, ſheathing at the baſe, ſo that the plant is rather ſtemleſs. Sheaths of the leaves alternate, half-embracing. Leaves filiform-ſubulate, compreſſed, plano-convex, ſlightly channelled, recurved at the end, pubeſcent and mealy with aſh-coloured ſcales. Peduncles terminating from the middle of the leaves, filiform, round, two or three inches long. Spathe two-leaved, two-flowered: leaflets equal, lanceolate-acuminate, concave, erect, mealy: one flower ſeſſile, the other peduncled within the ſpathe. Spathe one-leafed to each flower, ſheathing, lanceolate, ſmooth, aſh-coloured, incloſing the flower. Calyx three-leaved: leaflets lanceolate, concave, ſmooth, duſky red. Petals three, lanceolate, blue, blunt at the end, almoſt incloſed by the calyx. Filaments inſerted into the baſe of the corolla, awl-ſhaped. Anthers oblong, yellow. Style ſhort and thick. Stigma obtuſe, ſimple. Capſule long, round, awl-ſhaped, three-cornered,

[y] Swartz, deſcr. [z] Swartz, deſcr. [a] Idem, ibid.

Digitized by Google

nered, three-celled, three-valved: valves revolute. Seed-down capillary. Native of Jamaica, on old rotten trees [b].

16. Stem the bigneſs of a thread; the ſkin whitiſh as if covered with hoar froſt, within tough and black like a horſe-hair. Many of theſe together ſtick on the branches of the Ebony or other tree ſuperficially by the middle, and ſend down on each ſide ſome of the ſame ſtems, very often a yard long, hanging on both ſides, curled or turning and winding one within another, and reſembling an old man's beard, whence its common name in Jamaica. The ſtems are branched, and the branches which are two or three inches long, are ſet with roundiſh, white, froſted leaves. The flowers come out at the end of the branches [c].

This ſlender paraſitical plant is found upon the trees in many parts of Jamaica, but does not grow ſo common there nor ſo luxuriantly, as it does in the more northern provinces of the main continent, where it is ſaid to overrun whole foreſts. It is frequently imported to Jamaica from North America, for the uſe of the ſadlers and couchmakers, who commonly ſtuff their pannels, cuſhions, &c. with it.—In Louiſiana and the neighbouring ſettlements, this plant being very carefully gathered and ſtripped of the bark, is made into mattreſſes, cuſhions, pannels, &c. It is manufactured by tying the ſtalks in bundles, and ſinking them in water, or burying them under ground in a moiſt place, until the bark rots: they are then taken up, boiled in water, and waſhed until the fibres are quite cleared of the pulp. Theſe are not only uſed inſtead of horſe-hair, but are ſo very like it, that a man cannot diſtinguiſh them, without a ſtrict examination, and that even with a glaſs, unleſs he obſerves the branchings of it.

The Bonana bird's neſt is always made of the fibres of this plant, and is generally found hanging by a few threads, from the tops of the moſt expanded branches of the moſt lofty trees, eſpecially thoſe that ſpread over ponds or rivers [d].

The Renealmias of Plumier differing from his Caraguatas only in the fruit, and in that not very greatly, Linneus has united them.

DESCRIPTION, *&c.*

This is a tree of large ſize. The bark is very thick, rough and of a brown colour. The branches ſpread out wide on every ſide. Leaves alternate, oblong-ovate, four inches long, and two inches broad in the middle, rounded at the baſe, acuminate at the end, ſmooth, of a light-green colour, on very ſhort ſtrong foot-ſtalks. The flowers are produced in ſmall axillary racemes or bunches, each on a ſlender pedicel. The corolla has four narrow petals of a yellow colour, a little longer than the calyx, and a fifth, the claw of which is of the ſame length as the other petals, and the top ovate-cordate. Stamens within the tube, and terminated by oblong erect ſulphur-coloured anthers. Fruit roundiſh, the ſize of a large pea, divided into four cells, each containing one oblong-ovate ſeed.

Native of Spaniſh America, in the province of Tolu, behind Carthagena; whence Dr. Houſtoun ſent the ſeeds to England. [Mr. Miller therefore muſt have cultivated this tree before 1733, in which year the Doctor died.

Balſam of Tolu, which is brought to Europe in little gourd-ſhells, is obtained by making inciſions in the bark of the tree, and is collected into ſpoons, which are made of black wax, and from them it is poured into proper veſſels.

This Balſam is of a reddiſh yellow colour; tranſparent, in conſiſtence thick and tenacious: by age it grows ſo hard and brittle, that it may be rubbed into a powder between the finger and thumb. Its ſmell is extremely fragrant, ſomewhat reſembling that of lemons; its taſte is warm and ſweetiſh, and on being chewed it adheres to the teeth. Thrown into the fire, it immediately liquefies, takes flame, and diſperſes its agreeable odour. Though it does not diſſolve in water, yet if boiled in it for two or three hours in a covered veſſel, the water receives its odoriferous ſmell: water alſo ſuffers a ſimilar impregnation from the Balſam by diſtillation. With the aſſiſtance of mucilage it unites with water, ſo as to form a milky ſolution. It diſſolves entirely in ſpirit of wine, and eaſily mixes with diſtilled oils, but leſs eaſily with thoſe of the expreſſed kind. Diſtilled without addition, it produces not only an empyreumatic oil, but ſometimes a ſmall portion of a ſaline matter, ſimilar to that of the flowers of Benzoin.

Balſam of Tolu poſſeſſes the ſame general virtues with the balſams of Gilead and Peru; but it is leſs heating and ſtimulating, and may therefore be employed with more ſafety. It has been chiefly uſed as a pectoral, and is ſaid to be an efficacious corroborant in gleets and ſeminal weakneſſes. It is directed by the Pharmacopœias in *ſyrupus tolutanus, tinctura tolutana,* and *ſyrupus balſamicus* [e].]

PROPAGATION AND CULTURE.

Sow the ſeeds in pots filled with light earth, as ſoon as they arrive, and plunge them into the tan-pit. If they are not taken out of their covers, they will be long before they vegetate. When the plants are large enough to remove, tranſplant them carefully, each into a ſeparate pot, and plunge them into a good hot-bed of tanner's-bark, ſhading them from the ſun till they have taken new root. After which treat them in the ſame way as the Coffee Tree.

The ſeeds ſhould be gathered ripe, and whilſt freſh ſhould be put up in ſand; for when ſent over in papers, they are commonly devoured by inſects.

DESCRIPTIONS, &c.

1. Stem arboreous, lofty, branched, more than a fathom in height. Branches and branchlets tomentoſe, knobbed; the end ones angular. Leaves alternate, oblong, obtuſe, quite entire, erect, parallel-nerved, ſmooth and green above, beneath hoary-tomentoſe, a hand in length, the younger ones ſmaller. Petioles angular, ſtriated, tomentoſe, an inch long. Flowers axillary, collected into a head, pedicelled, dioecious. Peduncles angular, ſtriated, ſolitary, tomentoſe: with ſmall oppoſite tomentoſe bractes near the baſe. Pedicels within the head, very ſhort, five rarely ſix, one-flowered, tomentoſe, half a line in length.

Native of Japan; where it flowers in october and november[e].

2. Branches round, yellowiſh, the younger ones rough-haired. Leaves alternate, oblong-obovate, obtuſe, quite entire, veined, ſmooth except the midrib, which appears villoſe under the magnifier. Petioles half an inch long, rough-haired. Peduncles lateral on the naked part of the younger branches, from two to five-flowered. Involucre four-leaved, leaflets roundiſh, concave, pubeſcent, many-flowered, containing about twelve pedicelled flowers. Pedicels rough-haired. Calyx none. Corolla five-petalled, white: petals ſomewhat toothletted at the end. Nectaries club-ſhaped, green, ſhorter than the ſtamens. Filaments from twelve to ſeventeen, awl-ſhaped, hairy. Anthers oblong, flat, having four diſtinct ſegregate cells. Germ oblong. Style very ſhort. Stigma ſimple. Berry globular, red, the ſize of a red Currant, and containing one ſeed.—Native of China.

3. The Tallow Tree is a large tree, with round knobbed branches, covered with a yellow ſhining bark: the branchlets are covered with a fine down. Leaves ſcattered, obovate, obtuſe, or even oblong-lanceolate, quite entire, veined. Petioles an inch long, pubeſcent. Peduncles four-cornered, three or five-flowered, pubeſcent, axillary and lateral. Pedicels four-cornered, very rough-haired. — According to Klein, the involucre is four-leaved; the leaflets ovate, concave, tomentoſe on the outſide; and it incloſes from eight to ten apetalous floſcules on ſhort pedicels. Calyx none except the entire hairy margin, of the pedicel of the floſcules. Corolla none. The nectaries are little bodies at the baſe of the filaments. Theſe are from twelve to fifteen, filiform and hairy. Anthers oblong, ovate, grooved. Germ ovate, ſurrounded cloſely by the ſtamens. Style filiform, twice as long as the ſtamens. Stigma thickened, hollowed, with a reflexed margin. Berry one-ſeeded, globular[f].

According to Loureiro, it is a large tree, with ſpreading branches. Leaves ovate-oblong, quite entire, ſmooth, alternate, petioled. Peduncles lateral and ſubterminating, two or three-flowered. Berries ſmall, ſmooth, blackiſh.—Native of China and Cochinchina, in woods.

The wood, which is light and of a pale colour, is uſed for rafters, ſtuds, &c. in building. The leaves and twigs abound in a viſcid juice, and being bruiſed and macerated in water, render it glutinous; for this reaſon the natives work up their plaſter with it, to render it more tenacious and that it may laſt the longer. A great quantity of a thick white oil is extracted from the berries, of which common candles are made, reſembling ſpermaceti or wax candles, but having an unpleaſant ſmell[g].

Leaves obtuſe glandular-toothed.

DESCRIPTIONS, &c.

1. This is a tree with round branches, hairy at top, and covered with a purpliſh ſomewhat rugged bark. Leaves oppoſite, petioled, an inch and half long, diſtant, oblong, ending in a ſhort point, rigid, veined, ſomewhat rugged on both ſides, villoſe on the veins beneath: the younger ones have very minute dots ſcattered over them. Peduncles axillary, oppoſite, ſhorter by half than the leaf, tomentoſe, not at all rugged, branched with a dichotomous tip: branches and branchlets ſhort. Bractes lanceolate, ſmall, oppoſite, at the baſe of the branches and branchlets of the peduncle. Calyx five-cleft, with the ſegments toothletted at the edge. Petals like the calyx hoary, inſerted into the nectary below the margin by a ſhort claw, roundiſh, toothlet-ciliate, two a little ſmaller than the other three. Nectary margined, villoſe and ſomewhat ſilky within. Filaments inſerted into the diſk of the nectary, approximating to the ſtyle, lanceolate, compreſſed, ſhort. Anthers twin. Style conical, the length of the filaments. Stigma obtuſe. Aublet's figure is not a very good one[h].—He found it in Guiana, and von Rohr in the iſland of Trinidad.

2. This reſembles the preceding, but the leaves are ſmaller, obtuſe, and very ſeldom glandular-toothletted; the corollas are larger, and the anthers are ſeſſile.—Native of Guinea[i].

Umbellets remote, leaves doubly pinnate, pinnas gaſhed tomentoſe.

DESCRIPTIONS, &c.

1. This is a low plant, the ſtalks ſeldom riſing a foot high. The lower leaves are compoſed of two pairs of ovate leaflets terminated by a large one; they are hairy and ſlightly crenate. The ſtalks branch out into two or three diviſions, and are terminated by umbels of white flowers, which have large involucres, for the moſt part trifid. The points are lanceolate, and at their baſe is a ſmall umbel, compoſed of a few flowers ſitting cloſe to the tails of the involucres. [Seeds orbicular, compreſſed, very ſlightly convex in the middle, ſubpubeſcent, with a thick, ſuberous, white margin, crenulate with tubercles: belly part flat, ſmooth[k].

[h] Vahl. [i] Willdenow. [k] Gærtner.

Native

Native of Syria. Cultivated in 1597, by Gerarde. It flowers in july, and is annual *.

2. Root annual. Stem almoſt upright, branched, leafy, round, grooved, villoſe with ſoft ſhort deflected hairs. Leaves unequally pinnate, hairy, rugged; the radical ones on very long petioles, with ovate crenate ſublobed leaflets, the end one very large; ſtem-leaves alternate, ſubſeſſile, with oblong leaflets, ſharply ſerrate and gaſhed. Umbels on long peduncles, terminating. Involucres and involucrets briſtle-ſhaped, rugged. Flowers fleſh-coloured, with the outer petals very large and radiant *.

Native of the South of France, Italy and Sicily. Very doubtful whether it be indigenous of England. It is ſaid by Ray to have been found by Mr. Doody about Iſleworth; and Petiver ſays it grows about London. It is ſaid by Dillenius to have been found by Mr. James Sherard growing plentifully on the banks off the road to Headington, about half a mile from Oxford, probably from ſeeds of plants thrown out of a garden. Mr. Miller alſo ſays, that he has found it on the ſide of banks, but that the ſeeds were ſown there by Jacob Bobart. But they perhaps miſtook the T. apulum of Linneus for this plant, from which it is quite diſtinct: or confounded it with T. maximum.

3. Stem ſmooth, branched. Leaves like thoſe of Chervil. Univerſal umbel of about three rays; partial of about ſeven. Involucre of a ſingle linear leaf: involucrets of five leaflets, the length of the florets. All the florets fertile, floſcular, white. Seeds ovate, ſubcompreſſed, with three deep grooves, which are lamellated and plaited on the ſides.—Native of the Levant. *Arduini* °.

4. This is an annual, riſing, when in a garden, to the height of a foot and half: radical leaves growing in a circle, decumbent, and pinnated; with eight leaflets roundiſh or oblong, obtuſely toothed, and ſomewhat downy: ſtem-leaves ſmooth and ſharp: ſtems ſeveral, upright, ſtriated and branched; and at their lower parts clothed with white hairs: flowers white, with broad-lanced petals turning inwards ſo as to appear cordate: the exterior petal, in the exterior florets, bifid, with lanced diviſions: anthers yelloviſh-green, with browniſh ſides. The wild plant is more hairy than the cultivated one: flowers in july and auguſt P.

Linneus remarks, that the three marginal florets of each umbellet are larger or radiate.—Native of Italy in Apulia.

5. Root annual, tapering. Stems erect, three or four feet high, branched, leafy, flexuoſe, furrowed, rough with minute rigid briſtles, bent down cloſe, hollow within. Leaves unequally pinnate, rough with briſtles: leaflets of the lowermoſt ovate-oblong, lobed and notched; of the reſt lanceolate, narrow, coarſely but regularly ſerrate. Umbels on long ſolitary rough ſtalks, oppoſite to the leaves. General and partial involucres briſtle-ſhaped, rough. Central partial umbels nearly ſeſſile. Flowers white or roſe-coloured, with the outer petals larger and radiant. Seeds briſtly all over, with a circular pale or reddiſh edge, rugged but not ſo beautifully notched as in ſome other ſpecies q.

Native of Germany, Switzerland, Auſtria, France, Italy and England. On the north ſide of the Parks, Oxford; the only ſpot in Britain now known to produce it. Moriſon (umb. 40.) clearly mentions its growing about London in his time; but if Petiver's authority be of any weight, the Iſleworth plant muſt be T. officinale. It flowers from june to auguſt r. Miller ſets it down as a biennial plant; according to others the ſpecies, as far as we know, are all annual.

6. Stem a foot high, ſimple, furrowed, almoſt naked. Leaves unequally pinnate: lower ones half a foot long, embracing the ſtem with their membranaceous ſheaths, villoſe: leaflets two pairs, oblong, half-cordate, ſeſſile, toothed: the lower pair often two-lobed at the baſe; the end-leaflet larger and trifid half way. General involucre of one or two leaflets. General umbel of from ſeven to nine rays. Partial involucre ſpreading, linear, many-leaved. Petals red, one of them very large in the outer florets. Fruit ovate, margined, hiſpid. Native of Carniola *.]

7. The bottom leaves are double pinnate, each leaf having four pairs, and an odd one at the end. The pinnæ have ſeven ovate leaflets, ſtanding alternately, and deeply jagged, of a yelloviſh green colour and a little hairy. The ſtalks are taper and not channelled; they riſe two feet and a half high, have a few ſmall hairs ſcattered over them, and have one ſmaller pinnate leaf at each joint: they ſend out one or two ſhort branches towards the top, and are terminated by large umbels of yellow flowers, compoſed of ten umbellets, the rays of which are alternately longer; theſe ſpread open wide from each other. The ſeeds are ovate and compreſſed, ſhaped like thoſe of Parſneps, and of a yelloviſh colour. It flowers in june, and the ſeeds ripen in auguſt.

Native of Syria, eſpecially about Aleppo, where it is known by the name of Secacul, and is eaten crude by the inhabitants.

[TORDYLIUM Anthriſcus, latifolium, nodoſum. See *Caucalis*.

TORENIA. (*So named by Linneus from Olof Toreen, a Swediſh clergyman, who diſcovered this with other plants in China. His voyage to Suratte, China, &c. from* 1750 *to* 1752, *is printed with Oſbeck's voyage to China.*)

DESCRIPTIONS, *&c.*

1. [Root remarkably large and woody, brown on the outſide, red within. Stems weak, ſlender, wiry, naturally procumbent unleſs ſupported by ſurrounding plants; the flowering-branches only erect or aſcending; they are branched, leafy, round, clothed with ſhort ſoft erect hairs, a ſpan or more in length. Leaves alternate, ſeſſile or nearly ſo, ternate, lanceolate, marked with lines, deeply ſerrate, hairy: accompanied by a pair of ſtipules deeply divided into two, three or more lobes. Flowers on long capillary ſolitary peduncles, placed oppoſite to a leaf, or rather in the forks of the branches, ſupporting one flower. Segments of the calyx ovate, hairy, alternately larger and ſmaller, the latter exterior. Petals obcordate, of a golden yellow, frequently having an orange-coloured blotch at the baſe; claws very ſhort. Stamens about ſixteen, or from fourteen to eighteen. Piſtils from ſix to ſixteen. Germs hairy. Seeds few, wrinkled. Receptacle villoſe.

Native of Europe, in dry paſtures, eſpecially on heaths, among ſmall ſhrubs; flowering in june and july [x].

Some flowers are occaſionally found with five petals and ten ſegments of the calyx; yet this happens ſo rarely, and the two ſpecies of Tormentilla accord ſo well in habit, that we are not convinced of the propriety of conſidering them as Potentillæ.

Miſs Johnes obſerved one plant at Hafod, in which all the flowers were double [y].

Tormentil is a plant of conſiderable importance in œconomy and medicine. The roots are uſed in moſt of the Weſtern Iſles of Scotland, and in the Orkneys, for tanning leather; for which they are ſuperior even to oak-bark. They are firſt boiled in water, and the leather is then ſteeped in the cold liquor. In the iſlands of Tirey and Col the inhabitants have deſtroyed ſo much ground by digging them up, that they have been prohibited the uſe of them. They are alſo uſed for dying of a red colour [z]. And Mr. Young informs us, that many ſwine are reared with them on the mountains of Killarney.

The root of Tormentil has been long held in great eſtimation by phyſicians, as a very uſeful aſtringent; and as the reſin it contains is very inconſiderable, it ſeems more particularly adapted to thoſe caſes where the heating and ſtimulating medicines of this claſs are leſs proper; as phthiſical diarrhœas, diarrhœa cruenta, &c. Dr. Cullen thinks it has been juſtly commended for every virtue that is competent to aſtringents; and ſays, I myſelf have had ſeveral inſtances of its virtues in this reſpect; and particularly I have found it, both by itſelf and as joined with gentian, cure intermittent fevers; but it muſt be given in ſubſtance, and in large quantities. Rutty alſo recommends it in old putrid ulcers, in ſores of the mouth, throat and jaws, and in bleeding gums; and to reſtore the tone of the ſtomach. There is no vegetable, ſays he, of more efficacy in fluxes, fluor albus, &c.

This root may be given in powder from half a dram to one dram or more in a doſe, but it is more generally given in decoction. An ounce and half of the powdered root is boiled in three pints of water to a quart, adding, towards the end of the boiling, a dram of cinnamon: of the ſtrained liquor, ſweetened with an ounce of any agreeable ſyrup, two ounces or more may be taken four or five times a day. Tormentil is

ordered

Digitized by Google

ordered in *pulvis e creta compoſitus* of the London Pharmacopœia[a].

Farmers find the root very efficacious in the dyſenteries of cattle[b].

2. Root perennial, ſmall and ſlender. Stems few (one or two) eighteen or twenty inches long, ſimple, or ſometimes divided at top, flagelliform, pubeſcent, leafy, entirely proſtrate, but not taking root. The whole herb hairy, and of a light green. Radical leaves in fives, on long foot-ſtalks; ſtem-leaves in threes, on ſhorter foot-ſtalks; all obovate and deeply ſerrate: floral leaves ſeſſile, narrow and almoſt entire. Stipules lanceolate, commonly undivided. Peduncles ſolitary, longer than the leaves, oppoſite to a leaf or axillary. Corolla bright yellow, twice as large as in the common ſort: petals obcordate-roundiſh. Segments of the calyx ovate-lanceolate, unequal, hairy. Seeds wrinkled[c].

In Engliſh Botany, the ſtipules are ſaid to be more or leſs cut; and by Dr. Withering, that they are entire, with two or three clefts.

Native of Germany and England: with us it occurs about hedges and the borders of fields in dry places, but is by no means common. Ray remarked it in the borders of the corn-fields between Hockley and Shotover-woods, and elſewhere in Oxfordſhire. Dr. Sibthorp found it in the wood under Shotover-hill, and at Headington. Mr. Ray ſays it was found alſo in Braintree pariſh, Eſſex: and in Gibſon's edition of Camden's Britannia, it is ſaid to grow in a ditch between the Boarded-river and Iſlington-road. From Lightfoot's herbarium it appears that it was found in Surrey. Mr. Woodward obſerved it at Berkhamſtead in Hertfordſhire; Mr. Crowe, at Lakenham near Norwich; Dr. Smith at Brighouſe near Halifax, Yorkſhire; Mr. Caley about Mancheſter[d]; Dr. Pulteney, in Purbeck, in the cloſes at New Bridge between Ringwood and Wimbourne, under Hod-hill. Mr. Templeton aſſures me that it is not uncommon in Ireland.

Dr. Smith doubts whether Mr. Hudſon ever ſaw this plant; for if he had he could not have made it a variety of *Potentilla reptans*, though it ſometimes bears a corolla with five petals in the beginning of its flowering. The habit and appearance are as little like that ſpecies of Potentilla, as can well be, if accurately examined[e].

Mr. Afzelius remarked to Dr. Withering, that this plant differs from *Potentilla reptans* in having a trailing ſtem, not ſtriking root at the joints; whilſt that has a creeping ſtem, which takes root at every joint.—Here then, if we muſt change, is a better reaſon for changing the trivial name from *reptans* to *procumbens*, than in the caſe of the other ſpecies, from *erecta* to *officinalis*; for the ſtem is abſolutely not creeping in this; whereas it is often erect in the other, at leaſt the flowering-ſtems are aſcending. I have therefore left the trivial names as Linnæus gave them. I have alſo, on better grounds, retained the generic diſtinction of *Tormentilla* from *Potentilla*. Haller joined them both with *Fragaria:* and we may thus at any time croud an entire natural order into one genus.

Leaves ſublanceolate hoary, ſtem ſuffruticoſe.

DESCRIPTIONS, *&c.*

[1. This, and moſt of the other ſpecies are natives of South America. Many of them were firſt diſcovered by Father Plumier, who gave them the name of Pittonia, which Linneus changed to Tournefortia.

2. Stem ſhrubby, ſomewhat ſcandent, branched, covered with a ferruginous ſhagginefs. Leaves oblong, entire, nerved, hairy all over, but extremely ſo beneath. Spikes or racemes very much branched, ſtiff and ſtraight, ſpreading a little: flowers white, directed all one way. Filaments very ſhort. Anthers blackiſh green. Germ ovate. Stigma headed. Berry rugged-hirſute, when ripe white, two-celled with two ſeeds in each cell[f].

Browne ſays, this plant raiſes itſelf generally by the help of the neighbouring trees, and ſhoots ſometimes to a conſiderable height in the woods.]

According to Miller, it riſes to the height of eight or ten feet; the leaves are about four inches long, and two inches and a half broad, having many tranſverſe veins running from the midrib to the ſides; they are of a deep green on their upper ſide, and ſtand on ſhort hairy foot-ſtalks. The branches are terminated by very branching ſpikes of flowers; which are ſucceeded by ſmall, roundiſh, ſucculent fruit.—Native of the iſlands in the Weſt Indies.

[Cultivated by Mr. Miller in 1739.]

3. This has a twining woody ſtalk, which twiſts about the neighbouring trees for ſupport, and riſes to the height of ten or twelve feet, ſending out ſeveral ſlender woody branches. The flowers are produced in branching ſpikes from the ſide and top of the branches; they are ſmall and white; and are ſucceeded by ſmall white ſucculent berries, having one or two black ſpots on each.

[Gærtner deſcribes the berry as ſuperior, pulpy, globular flatted a little, ſubdiaphanous, one-celled, four-ſeeded, white with dark round ſpots correſponding in number and ſituation with the ſeeds. Stones diſtant, ſubglobular narrowing downwards, tubercled and wrinkled, two-celled. Seed one in each cell, curved inwards, brittle, pale.

Native of Jamaica. Cultivated in 1739 by Mr. Miller. It flowers in july and auguſt[g].

4. Branches, petioles, midrib of the leaves on both ſides, nerves beneath, and peduncles villoſe. Leaves petioled, alternate, two inches long, lower ones of the branches ſmaller, almoſt like thoſe of Lilac, (Syringa vulgaris) nerved, veinleſs, quite entire, very ſmooth except on the nerves. Peduncle terminating, erect, ſeveral times divided dichotomouſly. Spikes pubeſcent, two inches long, reflexed as in the other ſpecies. Flowers alternate, approximating. Corollas ſomewhat villoſe on the outſide; the ſegments of the border very narrow and ſomewhat briſtle-ſhaped. Found in Cayenne by von Rohr[h].]

[f] Swartz. [g] Hort. kew. [h] Vahl.

5. Stems ſhrubby, ten or twelve feet high, ſending out many branches. Leaves alternate, five inches long, two inches and a half broad in the middle, hairy on their under ſide, ſtanding upon ſhort foot-ſtalks. The branches are terminated by long branching ſpikes of flowers, ranged on one ſide like thoſe of the Heliotrope or Turnſol. Some of the foot-ſtalks ſuſtain two, others three, others again four ſpikes of flowers, near five inches in length, reflexed at the top. The flowers are of a dirty white colour, ſmall, and cloſely ſet. They are ſucceeded by ſmall ſucculent fruit, incloſing four oblong ſeeds.

Native of Jamaica and other iſlands of the Weſt Indies. Cultivated by Mr. Miller in 1739.

6. This plant has low ſhrubby ſtalks, which ſeldom riſe more than three feet high, ſending out a few ſlender woody branches. Leaves rough, dark green on their upper, but pale on their under ſurface. The flowers come out in ſingle axillary ſpikes; they are white, and are ſucceeded by ſmall ſucculent berries.

Native of South America: found at Campeachy by Dr. Houſtoun; [and therefore cultivated by Mr. Miller, not only in 1739, but probably before 1733.

This plant is repeated in Linneus's ſpecies under the name of *Heliotropium fruticoſum*, and has been already deſcribed in this work from Miller, Swartz and Browne, under that title.

7. This is a ſhrub, a fathom in height. Trunk round, branched, even: branches alternate, almoſt upright, round, ſmooth. Leaves alternate, entire, nerved, veined, ſmooth on both ſides, ſomewhat wrinkled above and ſometimes but very ſeldom rough-haired, even beneath and pale; hence the trivial name of *bicolor* or two-coloured: petioles of a middling length and even. Spikes terminating, branched; branchlets recurved, rough-haired, many-flowered. Calyx even. Corollas greeniſh-white, with a hirſute hoary tube.

It differs from *fœtidiſſima*, in having ſmaller leaves, ſomewhat ſmooth; and ſpikes in cymes, reflexed, upright:—from *cymoſa*, in its leaves, and in the ſpikes not being pendulous, looſe: from *birſuta*, in the leaves not being hirſute; the ſpikes leſs branched, with the flowers more crouded together.

Native of Jamaica, in coppices[i].

8. Stem a fathom in height. Branches herbaceous, angular, grooved, ſmooth. Leaves ovate-lanceolate, long, petioled, ſmooth, wrinkled beneath. Flowers ſeſſile, on one ſide, diſpoſed in two rows. Corollas longer, five-cornered, greeniſh-white. Stigma headed. Berry roundiſh, white, with one pore at the top, two-celled, with two ſeeds in each cell[k].

Gærtner deſcribes the berry (when old and dry) to be tranſverſely oblong, acuminate at both ends, reſembling a double cone, grooved, of a ſmoky reddiſh colour. Stones irregularly conical, grooved, three-celled; the two inner cells fertile, the third outer conſtantly empty. Seeds oblong, narrowing downwards, ſlightly curved, ſnow-white.

Gærtner remarks, that the radicle in Tournefortia being inferior, it approaches nearer to the Verbenæ of Adanſon, than the Aſperifoliæ. He ſays that he never could diſcover the double pore in the top of the berry; and therefore concludes that the character is erroneous, or at leaſt not general. Perhaps this may be owing to his having examined none but dry berries. Swartz, as we have ſeen, deſcribes one pore in this ſpecies. This author obſerves that the whole plant is fetid.

Native of Jamaica; where Browne ſays it is ſometimes obſerved in the woods; that it generally riſes from five to ſeven or eight feet in height, and is remarkable for the thickneſs of its upper branches, and the length of its pendulous flower-ſpikes: the leaves are very large, ſometimes a foot or more in length.

It was cultivated in 1777, by Mr. William Malcolm; and flowers in july[l].

9. This is a ſhrub, ſcarcely the height of a man. Trunk very ſhort, covered with a deeply cloven bark. Branches ſpreading very much, hirſute. Leaves at

[i] Swartz, deſcr. [k] Swartz, obſ. [l] Hort. kew.

the

Digitized by Google

the ends of the branches, alternate approximating into a roſe as in Sempervivum canarienſe, ovate or tongue-ſhaped, (being narrowed into the petiole,) ſeſſile, rounded at the end, white all over with a ſilky hairineſs preſſed cloſe to them. Panicle large, divided into ſpikes, directed one way, and rolled back. Flowers ſnow-white; tube ſhort; border recurved. Berries not perforated. It is the handſomeſt ſpecies of the genus.

Native of the ſhores of the ſea of Ceylon[m]. Alſo of the Friendly Iſles[n].

10. This has the appearance of T. volubilis. Branches ſlender, round, ſmooth below, villoſe-aſh-coloured above. Leaves petioled, alternate, an inch and half long, little attenuated, acute, quite entire, above ſimply veined, ſmooth, beneath ſomewhat ſilvery, with veins a little branched. Peduncles flexuoſe, villoſe, aſh-coloured, with ſpreading branches. Flowers ſmall, diſtinct, alternate. Corolla villoſe on the outſide; with briſtle-ſhaped ſegments. Found in Montſerrat by Ryan[o].]

11. This has woody ſtalks which riſe five or ſix feet high, from which ſpring out many ſlender woody branches. Leaves about two inches long, and an inch broad in the middle, rounded at each end but having acute points; of a dark green on their upper ſurface, but having a white down on their under ſide, and ſitting cloſe to the branches. Flowers terminating and axillary, in ſlender branching ſpikes, which are recurved; and the flowers are ranged on one ſide of them; they are white, and are ſucceeded by ſmall ſucculent berries, which contain two or three ſeeds.

[Native of Jamaica. Dr. Browne ſays it is found by the ſea-ſide, near the borough in St. James's; and ſeldom riſes above three or four feet. According to Mr. Miller, it was diſcovered by Mr. Robert Millar near Carthagena in New Spain.—He cultivated it in 1768[p], and probably much ſooner, if it was ſent him by Robert Millar.

Mr. Miller has three other ſpecies, one found by Houſtoun, a ſecond by Robert Millar, and a third by Plumier.]

1. Tournefortia ſcandens. *n.* 4.
Pittonia ſcandens racemoſa, flore fuſco. *Houſt. MSS.*
Leaves cordate hirſute, ſpikes racemed reflexed, ſtem twining.

Stems ſhrubby, branching, riſing to the height of ten or twelve feet. Leaves near three inches long, and an inch and half broad near the baſe, ending in acute points; they are of a thinner texture than in T. volubilis, and ſtand upon ſhort foot-ſtalks. The flowers come out at the ends of the branches in very ſlender branching ſpikes; they are ſmall, and of a dirty brown colour, ranged along the upper ſide of the peduncle. Berries ſmall, pulpy, containing four ſeeds. Diſcovered in Jamaica by Dr. Houſtoun, who ſent the ſeeds to England.

2. Tournefortia tomentoſa. *n.* 5.
Pittonia ſcandens racemoſa, foliis ſubrotundis ſubtus incanis. *Houſt. MSS.*
Leaves cordate tomentoſe beneath, ſpikes racemed ſhort, ſtem twining.

This has climbing ſtalks, which twine about any neighbouring ſupport, and riſe to the height of ten or twelve feet. Leaves two inches long, and an inch and quarter broad near their baſe, on very ſhort foot-ſtalks. Spikes axillary. Flowers of a dirty white colour, ſmall; ſucceeded by ſmall ſucculent berries, incloſing two, three and ſometimes four ſeeds. Found by Mr. Robert Millar near Carthagena in New Spain.

3. Tournefortia carnoſa. *n.* 6.
Pittonia fruteſcens, folio carnoſo hirſuto & obtuſo. *Plum. gen.* 5.
Leaves ovate wrinkled petioled, ſpikes racemed axillary, ſtem ſhrubby.

This has a ſtrong woody ſtalk, which riſes near twenty feet high, ſending out ſeveral ſtrong woody branches, covered with a light-brown rough bark. Leaves thick, four inches long and three broad, very rough and of a dark green colour on their upper ſurface, but pale and ſmoother on their under ſide, ſtanding upon pretty long foot-ſtalks. Flowers in branching axillary ſpikes, ſmall and white; ſucceeded by ſmall ſucculent berries, incloſing two or three oblong ſeeds. Found by Mr. Robert Millar, near Carthagena in New Spain.

[Loureiro has a ſpecies which he names *Tournefortia montana*. Willdenow doubts whether it may not be a *Meſſerſchmidia*.]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds, which muſt be procured from the countries where they grow naturally; theſe ſhould be ſown in ſmall pots filled with light earth, and plunged into a hot-bed of tanners bark. Theſe ſeeds ſometimes grow the firſt year, but they often remain in the ground a whole year; therefore, if the plants ſhould not come up the ſame ſeaſon, the pots ſhould be plunged in autumn into the tan-bed in the ſtove, where they ſhould remain all the winter, and in the ſpring they ſhould be removed out, and plunged into a freſh tan-bed, which will ſoon bring up the plants if the ſeeds were good. When theſe are fit to remove, they ſhould be each planted in a ſmall pot, and plunged into a tan-bed, where they muſt be ſhaded from the ſun till they have taken new root, and then they muſt be treated in the ſame way as other tender plants from the ſame countries, which require to be kept conſtantly in the bark-ſtove. They may alſo be increaſed by cuttings.

Nearly upright, leaves linear ciliate biſpid.]

DESCRIPTIONS, *&c.*

1. Root perennial, fleſhy, tuberous, ſending out many fibres which ſpread wide on every ſide. Leaves about two inches long, and one inch broad in the middle, ending in acute points. The ſtalks riſe a foot and half high, with leaves on them ſhaped like thoſe at the bottom. Sometimes there are two pretty large leaves, and one or two ſmaller from the ſame point, or one large and three ſmaller; theſe come out alternate, and the upper part of the ſtalk, immediately under the umbel, is naked, except two or three narrow leaves, which are cloſe to the foot-ſtalks of the flowers: theſe are diſpoſed in form of an umbel compoſed of many ſmall ones. The flowers are ſmall, and of an azure blue colour, appearing in june and july. The ſeeds ripen in ſeptember.

[Capſule inferior, crowned with a ſhort calyx, ſmall, ſubglobular, rounded-three-cornered, and flatted at the ſides, as it were three-lobed, triple-nerved at the lobes. Receptacle ovate-globular, ſmall, excavated, faſtened to the internal angle of each cell about the middle. Seeds of an oblong elliptic form, compreſſed like a lens, ſmooth, ſhining, of a pale ruſt-colour[t].

Native of Italy and the Levant, in ſhady places. Cultivated by Mr. Miller in 1739. Biennial[u].

It has the name of Trachelium and Throatwort from the length of the neck, throat or tube of the corolla.

2. The branches are frequently ſo divaricated as to be recurved.

3. This and the preceding are natives of the Cape of Good Hope, where they were found by Thunberg[x].]

PROPAGATION AND CULTURE.

1. This plant is propagated by ſeeds, which ſhould be ſown in autumn when they are ripe, for when they are kept out of the ground till ſpring, they frequently fail, or if they do grow, it is not before the following ſpring. When the plants come up, they ſhould be kept clean from weeds, and as ſoon as they are big enough to remove, they ſhould be tranſplanted on an eaſt-aſpected border of light undunged earth, placing them in rows ſix inches apart, and four inches diſtant in the rows, ſhading them from the ſun till they have taken new root; after which they require no other care but to keep them clean from weeds till autumn, when they may be tranſplanted into the borders of the flower-garden, where they will flower the following ſummer.

But as theſe plants will thrive better on old walls, when by accident they have ariſen from ſeeds, ſo their ſeeds, when ripe, may be ſcattered on ſuch walls as are old, or where there is earth lodged ſufficient to receive the ſeeds; where the plants will come up and reſiſt the cold much better, and continue longer than when ſown in the full ground; and when a few of the plants are eſtabliſhed on the walls, they will ſhed their ſeeds, ſo that they will maintain themſelves without any farther care. I have obſerved ſome plants of this kind, which have grown from the joints of a wall, where there has not been the leaſt earth to ſupport them, which have reſiſted the cold, though they

[r] L'Heritier. [s] Haller. [t] Gærtner. [u] Hort. kew. [x] Linn. ſuppl.

OBS. *The form of the ſtyle varies. Some of the ſpecies* (8. 10. 11. 12. 19.) *have naked filaments.* T. monandra *has only one ſtamen, and* cordifolia *three.*

ESSENTIAL CHARACTER.

Cal. three-leaved. *Pet.* three. *Filam.* equal, with jointed hairs. *Capſ.* three-celled.

SPECIES.

1. Tradeſcantia virginica. *Common Virginian Spiderwort.*
   Lin. ſpec. 411. *ſyſt.* 314. *Reich.* 2. 10. *Willd.* 2. 16. *hort. cliff.* 127. *upſ.* 73. *Gron. virg.* 36. *Gærtn. fruct.* 1. 51. *t.* 15. *Knipb. cent.* 6. *n.* 96. *Curt. magaz. t.* 105.
   Ephemerum phalangoides tripetalum non repens virginianum gramineum. *Mor. hiſt.* 3. 606. *ſ.* 15. *t.* 2. *f.* 4.
   E. virginianum. *Tournef. inſt.* 367. 368.
   Phalangium Ephemerum virginianum. *Park. parad.* 152. *n.* 5. *t.* 151. *f.* 4.
   P. virginianum Tradeſcanti. *Ger. emac.* 49. *f.* 5. *Raii hiſt.* 1193.
   Allium ſ. Moly virginianum. *Bauh. pin.* 506.
   Erect, leaves lanceolate ſmooth, flowers heaped in an umbel terminating.

[2. Tradeſcantia craſſifolia. *Thick-leaved Spiderwort.*
   Lin. ſpec. ed. Willd. 2. 17. *Cavan. ic.* 1. 54. *t.* 75.
   Erect, leaves ovate woolly at the edge and beneath, flowers heaped in umbels terminating.

3. Tradeſcantia erecta. *Upright Spiderwort.*
   Lin. ſpec. ed. Willd. 2. 17. *Cavan. ic.* 1. 53. *t.* 74. *Jacqu. collect.* 4. 114. *ic. rar.* 2. *t.* 354.
   T. undulata. *Vahl act. ſoc. hiſt. nat. hafn.* 2. *p.* 2. 27. *t.* 3.
   T. bifida. *Roth. catal. bot.* 1. 42.
   Erect, leaves ovate narrowed at the baſe ſmooth, peduncle terminating naked bifid racemed.]

4. Tradeſcantia Zanonia. *Gentian-leaved Spiderwort.*
   Lin. ſpec. ed. Willd. 2. 17. *Swartz prodr.* 57. *deſcr.* 1. 604.
   Commelina Zanonia. *Lin. ſpec.* 61. *Mill. dict.* and *Dict. noſtr. n.* 7.
   Periclymenum rectum herbaceum gentianæ folio, foliis pediculo caulem ambiente. *Sloan. jam.* 1. 243. *t.* 147. *f.* 1.
   Erect, leaves broad-lanceolate, peduncles lateral ſolitary jointed in the middle many-flowered, bractes in pairs.

[5. Tradeſcantia diſcolor. *Purple-leaved Spiderwort.*
   Lin. ſpec. ed. Willd. 2. 18. *L'Herit. ſert. angl.* 8. *t.* 12. *Swartz deſcr.* 1. 607. *Smith ic. rar. t.* 10. *Ait. kew.* 1. 403.
   T. ſpathacea. *Swartz prodr.* 57.
   Stemleſs even, bractes equitant compreſſed, leaves lanceolate coloured underneath.

6. Tradeſcantia malabarica. *Graſs-leaved Spiderwort.*
   Lin. ſpec. 412. *Reich.* 2. 11. *Willd.* 2. 18.
   Ephemerum tripetalum non repens malabaricum, poraceis foliis, purpureo-cæruleum. *Mor. hiſt.* 3. 606?
   Ephemeri ſ. Phalangii virginiani ſpecies, floribus ſparſis. *Raii ſuppl.* 564?
   Tali-pulli. *Rheed. mal.* 9. 123. *t.* 63.
   Erect even, peduncles ſolitary very long.

7. Tradeſcantia nervoſa. *Nerve-leaved Spiderwort.*
   Lin. ſyſt. 315. *Reich.* 2. 11. *Willd.* 2. 18. *mant.* 223.
   Scape one-flowered.

8. Tradeſcantia divaricata. *Straddling Spiderwort.*
   Lin. ſpec. ed. Willd. 2. 18. *Vahl. ecl.* 1. 34.
   Commelina hexandra. *Aubl. guian.* 1. 35. *t.* 12.
   Stem dichotomous, leaves ovate-lanceolate ſmooth, ſheaths villoſe, flowers panicled, filaments ſmooth.

9. Tradeſcantia geniculata. *Knotted Spiderwort.*
   Lin. ſpec. 412. *ſyſt.* 315. *Reich.* 2. 11. *Willd.* 2. 19. *Jacqu. amer.* 94. *t.* 64. *pict.* 49. *t.* 95.
   Ranunculus ſ. Damaſonium repens, parnaſſiæ foliis villoſis. *Plum. ic.* 116. *f.* 2.
   Procumbent hirſute.

10. Tradeſcantia monandra. *One-ſtamened Spiderwort.*
    Lin. ſpec. ed. Willd. 2. 19. *Swartz prodr.* 57. *deſcr.* 1. 597.
    Diffuſed, leaves ovate-acuminate, peduncles axillary many-flowered, flowers one-ſtamened.

11. Tradeſcantia multiflora. *Many-flowered Spiderwort.*
    Lin. ſpec. ed. Willd. 2. 19. *Swartz prodr.* 57. *deſcr.* 1. 599.
    Erect branched, leaves cordate ciliate on the edge and ſheaths, peduncles cluſtered axillary, flowers three-ſtamened.

12. Tradeſcantia cordifolia. *Heart-leaved Spiderwort.*
    Lin. ſpec. ed. Willd. 2. 19. *Swartz prodr.* 57. *deſcr.* 1. 601.
    Creeping filiform, leaves cordate, peduncles terminating ſolitary many-flowered.

13. Tradeſcantia procumbens. *Trailing Spiderwort.*
    Lin. ſpec. ed. Willd. 2. 19.
    T. multiflora. *Jacqu. collect.* 3. 226. *ic. rar.* 2. *t.* 355.
    Stem procumbent rooting, leaves ovate ciliate at the baſe ſheathing, peduncles cymed axillary, ſtamens unequal.

14. Tradeſcantia axillaris. *Axillary Spiderwort.*
    Lin. ſyſt. 315. *Reich.* 2. 11. *Willd.* 2. 20. *mant.* 321. *Roxb. corom.* 2. 5. *t.* 107.
    Commelina axillaris. *Lin. ſpec.* 62.
    Ephemerum phalangoides maderaſpatanum minimum, ſecundum caulem quaſi ex utriculis floridum. *Pluk. phyt. t.* 174. *f.* 3.
    E. malabaricum, flore tripetalo in foliorum alis ſeſſili. *Raii ſuppl.* 567.
    Nir-pulli. *Rheed. mal.* 10. 28. *t.* 13.
    Stem branched, flowers ſeſſile lateral.

15. Tradeſcantia formoſa. *Handſome Spiderwort.*
    Lin. ſpec. ed. Willd. 2. 20.
    T. ſpecioſa. *Lin. ſyſt.* 315. *ſuppl.* 192.
    T. nodiflora. *Lamarck, encycl.* 2. 367.
    Commelina ſpecioſa. *Thunb. prodr.* 59.
    Leaves oppoſite connate.

16. Tradeſcantia criſtata. *Creſted Spiderwort.*
    Lin. ſyſt. 315. *Reich.* 2. 12. *Willd.* 2. 21. *Jacqu. hort.* 2. 64. *t.* 137.
    Commelina criſtata. *Lin. ſpec.* 62. *fl. zeyl. n.* 32.
    Ephemerum zeylanicum procumbens inflatum. *Herm. parad.* 148. *Raii hiſt.* 566.
    Creeping even, ſpathes two-leaved imbricate.

17. Tradeſcantia papilionacea. *Papilionaceous Spiderwort.*
    Lin. ſyſt. 315. *Reich.* 2. 12. *Willd.* 2. 21. *mant.* 61. 513. *Burm. ind.* 17. *t.* 7. *f.* 1. *Vahl ſymb.* 1. 27.

Tillandſia decumbens. *Forſk. deſcr.* 72. *n.* 23. β.
Creeping even, ſpathes three-leaved imbricate.

18. Tradeſcantia tuberoſa. *Tuberous-rooted Spiderwort.*
Roxb. corom. 2. 5. *t.* 108.
Roots tuberous, joints of the ſtem radical, bractes in two rows, falcate, ciliate.

19. Tradeſcantia paniculata. *Panicled Spiderwort.*
Roxb. corom. 2. 6. *t.* 109.
Stems creeping, panicle terminating many-flowered.]

DESCRIPTIONS, &c.

1. Roots compoſed of many fleſhy fibres. Stalks ſmooth, riſing a foot and half high. Leaves long, ſmooth, keeled, embracing. Flowers in cluſters, compoſed of three large ſpreading purple petals: they appear early in june; and though each flower continues but one day, whence this plant had the name of Ephemerum, yet ſuch is the profuſion, that there is a ſucceſſion of them through the greater part of the ſummer. [Some authors have named it *Phalangium*, from its ſuppoſed property of curing the bite of a ſpider.

Capſule ſuperior, wrapped up in the permanent corolla, ſmall, marked with three grooves; the valves bearing the partition in the middle. Seeds two in each cell, of which one only uſually comes to maturity; this is elliptic, plano-convex, aſh-coloured: the belly flat, with a ſlender ridge, near which are tranſverſe wrinkles on each ſide; the back is convex, wrinkled radiately at the periphery, and having a little teat, which bears the embryo, in the middle[f].

Gærtner remarks, that Tradeſcantia and Commelina form but one natural genus.

The fine blue of the corolla, with the hairy filaments of the ſame colour in the middle, tipped with the large yellow anthers, would render this a favourite flower if it were not ſo common.

Native of Virginia and Maryland. Introduced before 1629, by Mr. John Tradeſcant Senior[g]. The Spider-wort, ſays Parkinſon, is of late knowledge, and for it the Chriſtian world is indebted unto that painful induſtrious ſearcher, and lover of all nature's varieties, John Tradeſcant, (ſometimes belonging to the Right Honourable Lord Robert Earle of Saliſbury, Lord Treaſurer of England in his time, and then unto the Right Honourable the Lord Wotton at Canterbury in Kent, and laſtly unto the late Duke of Buckingham,) who firſt received it of a friend, that brought it out of Virginia. Johnſon, the editor of Gerarde's herbal adds: this Virginian is in many of our Engliſh gardens, as with Mr. Parkinſon, Mr. Tradeſcant, and others.]

There are two varieties, one with a deep blue, and the other with a white flower, but they vary from one to another when raiſed from ſeeds.

[2. The whole plant is villoſe or woolly; the ſtem is branched, and a foot and half high; the leaves are thick ovate acute cowled at the baſe or very ſhortly ſheathing nerved, ſmooth above, but woolly beneath and at the edge: the flowers are among the largeſt of the genus[h]: the petals being above half an inch in diameter, orbicular and curled at the edge: the filaments are blue-bearded, and the anthers very dark blue.—Native of Mexico[i]. Cavanilles ſaw it flowering in the royal garden of Madrid in october.

3. Stems herbaceous, thick, round, jointed, three feet high, branched; branches axillary, and while tender villoſe. Leaves alternate, broad-ovate, acuminate at both ends, terminating at the baſe in an embracing ſheath. Both common and partial peduncles villoſe; as are alſo the calyx-leaves on the outſide. Corolla purple-violet, a little bigger than the calyx, petals orbicular with ſhort claws. Filaments red; the three lower ones longer; the loweſt beardleſs, the reſt bearded with little jointed briſtles: thoſe of the upper ones of a golden colour, of the two lateral ones purple: anthers on the longer filaments violet, loaded with pollen; on the ſhorter ones yellow, ſeeming to have no pollen. Germ ſuperior, white, oblong-three-ſided: ſtyle red, ſomewhat bowed. Seeds rough with tubercles, three or four in each cell.—It varies with violet-coloured corollas and ſtamens in the ſame umbel.—This is an annual plant, whereas the preceding is perennial. Native of Mexico[k].—Cavanilles ſaw it flowering and fruiting in the royal garden at Madrid in october.

4. Plant herbaceous, two feet high. Stem ſimple, jointed, round, ſheathed, almoſt naked below, ſmooth, ſucculent. Leaves ſubſeſſile, attenuated at the baſe, ſheathing, alternate, acuminate, entire, nerved longitudinally, ſmooth above, pubeſcent or villoſe beneath, almoſt a foot long: ſheaths ovate, half an inch long, diſtant from the ſtem, membranaceous, nerved, ſhrivelling, at the edge hirſute, ciliate. Peduncles oppoſite to a leaf, round, elongated, length of the leaves, ſurrounded at the baſe with a ſheath, which is cowled, membranaceous, retuſe; they are jointed in the middle, and at the joint there is an acuminate ſheath. Flowers terminating, from ſix to eight, on very ſhort pedicels, which are cluſtered, thickened, and unequal; they gradually erect themſelves as they flower, and are again turned back as the flowers go off. Under each pedicel is a two-leaved involucre, or two bractes, which are oppoſite, ovate, acuminate, entire, nerved, reflexed, ſmooth. Calyx ſomewhat pitcher-ſhaped, trifid at the baſe: leaflets ovate, acute, concave, incloſing the corolla. Petals a little bigger than the calyx-leaves, ovate-acute, erect, waved at the edge, white or hyaline. Filaments length of the petals, villoſe in the middle, equal. Anthers double, three-cornered, uniform. Germ oblong, placed on the middle of the calyx. Capſule berried, oblong, three-cornered, when ripe very dark purple, placed obliquely on the pedicel. Native of the ſouthern parts of Jamaica, in mountain woods; flowering in the ſpring months[l]. Alſo found in Guiana. See farther under *Commelina Zanonia.*

5. Root perennial, vertical, fleſhy, knotty. Leaves radical, numerous, embracing each other, ſpreading, a foot long, ſharpiſh, entire, fleſhy, ſlightly ribbed, ſmooth on both ſides, a little downy at the edges of the baſe, green above, bright purple on the margins and under ſide, the younger ones ſomewhat channelled. Stipules none. Stalks axillary, four times ſhorter than the leaves, ſolitary, erect, ſimple, rarely divided, a little compreſſed, ſmooth, whitiſh. External bractes ſheath-like, ſlightly ribbed, purpliſh, ſmooth, poliſhed on the inſide; of which the loweſt are the ſmalleſt, thinneſt, embracing the ſtalk, and alternate; the uppermoſt ſcarcely ever more than two, very large, formed like a boat, ſomewhat heart-ſhaped at the baſe, embracing each other, ending in a point: internal bractes ſcaly, membranous, white and pellucid, three times ſhorter than the outer ones. Flowers numerous, between the uppermoſt external bractes, which they ſcarcely riſe above, ſeparated and enfolded in diſtinct cluſters by the internal ones, pedicelled, white, ſhort-lived and ſcentleſs. Pedicels ſimple, ſingle-flowered, roundiſh, a little ſwelled in the upper part, whitiſh ſometimes green at the top, ſmooth, poliſhed, curved after flowering. Calyx corolla-like, whitiſh, pellucid, ſmooth: leaflets equal, obtuſe. Petals a little longer than the calyx, and alternate with its leaflets, broad-oval, obtuſe, waved at the margin, when faded rolled inward. Filaments as long as the corolla, nearly equal, almoſt erect, white, clothed a little above the baſe with numerous very ſlender white pellucid hairs, which are moſt beautifully jointed like a Conferva, and are ſomewhat ſhorter than the ſtamen, ſtanding nearly erect. Anthers wedge-ſhaped, vertical, yellow, ſmooth, entire at the top, bearing pollen at their orange-coloured edges. Germ ſuperior, roundiſh, triangular, ſmooth, white. Style erect, cylindrical, white and ſmooth. Stigma ſmall, obtuſe, rough. Capſule ſcarcely ſo large as a pea, ſmooth, turning red. Seeds ſolitary, ſomewhat kidney-ſhaped.

Native of South America, on the Moſquito ſhore; whence it was brought by a ſhip to Jamaica, where it was obſerved and deſcribed by Maſſon[m]; and ſent

[f] Gærtner. [g] Hort. kew. [h] Willdenow. [i] Cavanilles. [k] Cavanilles. [l] Swartz deſcr. [m] Smith.

Digitized by Google

to Europe in 1783, by Matthew Wallen, Esq. It flowers most part of the summer.

6. Native of the East Indies. Introduced in 1776, by John Fothergill, M. D. It flowers in july and auguſt[n].

7. Stems a hand high, diffuſed. Leaves lanceolate, ſheathing, ſhort or an inch long, cluſtered. Peduncle terminating, filiform, long, one or two-flowered. Bracte obſolete, remote from the flower. Flower large. Calyx-leaves lanceolate, ſcarioſe, five-nerved, ſhorter than the corolla. Petals ovate, broad, many-nerved. Filaments with violet-coloured hairs. Style hooked at the end. Suppoſed to be a native of Suratte. From Mutis[o].

8. Stem dichotomouſly branched. Branches round, divaricating, broken in at bottom, jointed: joints two inches and more, gradually ſhorter upwards, ſmooth below, little villoſe above, ſheathed. Sheaths tubular, ſhorter by half than the joint, membranaceous, dry in ſummer, ciliate at the edge with long hairs, more villoſe on the alternate ſides. Leaves from the margin of the ſheaths, alternate, ſubpetioled, two inches long or more, the lower ones a little ſmaller, attenuated, acute, quite entire, flat, marked with about fifteen very fine nerves. Panicle terminating, erect, two inches long. Pedicels ſhort, three or four-flowered, reflexed, villoſe. Bractes lanceolate, membranaceous, villoſe, length of the pedicels. Calyx inferior: leaflets oblong, obtuſe, appearing a little villoſe under the magnifier, equal. Petals equal, ovate, acute, longer than the calyx, blue. No nectary. Filaments inſerted at the baſe of the petals, ſhort, very ſmooth. Anthers erect, awl-ſhaped, twice as long as the filaments, but ſhorter than the corolla. Germ ſmooth, ſubglobular-three-ſided, with obtuſe angles. Style permanent, a little ſhorter than the anthers. Stigma ſimple, obtuſe. Capſule rounded-three-cornered, twice as large as a pea, muricated on the outſide with ſmall ſcattered tubercles: valves membranaceous, oblong, mucronate, flatted longitudinally at the back in the part correſponding with the partition within: partition ventral. Seeds two, ſeldom three in each cell, arilled, all coming to maturity, ovate-ſubtriangular, flat where they touch each other, blunt at the other end, convex at the back, flat at the belly on each ſide. Aril looſely covering the whole ſeed, membranaceous and ſomewhat pulpy, when the ſeed is dry collapſing and aſſuming the ſhape with the inequalities of the ſeed, but eaſily ſeparating from it. Seed itſelf oblong, plano-convex, ferruginous, dry, brown, flattiſh on the belly, tranſverſely wrinkled on both the ſides, having in the middle a ſmall excavation with a teatlet, to which the aril adheres; convex on the back, with a navel-ſhaped excavation in the middle, and wrinkled at the ſides, as on the belly.—It differs therefore both from Commelina and Tradeſcantia in having an aril or looſe membranaceous coat adhering to the umbilicus: and ſince it has no nectaries, and the filaments are not bearded, might it not conſtitute a genus ſeparate from both[p]?

Found on the banks of rivers in Guiana and Cayenne by Aublet, and in the iſland of Trinidad by Ryan.

9. This is a tender plant, with herbaceous round jointed ſtems, creeping at bottom, otherwiſe nearly upright. Leaves cordate, acuminate, embracing, ſheathing, quite entire, alternate, hirſute eſpecially at the edges. Panicles dichotomous, terminating and axillary, erect. Flowers ſmall, with white corollas.—In Plumier's figure, the plant is repreſented too hairy, which is a common fault in his plates[q].

Native of South America—Martinico, in moiſt hedges.

10. Root annual. Radicles very long, whitiſh. Stem herbaceous, aſcending, jointed, putting out fibres, half a foot high, looſe, round, pellucid, ſmooth, ſpotted: branches nearly upright, looſe, round, ſpotted. Leaves ſubpetioled, alternate, entire, very thin, longitudinally and very finely nerved, very ſmooth. Petioles (or the baſe of the leaf attenuated) ſheathed: ſheaths ſhort, cowled, or diſtant from the ſtem, membranaceous, whitiſh, rough-haired or ciliate at the edge. Peduncles principally from the ſheaths of the terminating leaves, often longer than the leaves, looſe; flowers in umbellets, eight or ten together: involucrets or little bractes three or four-leaved: leaflets minute ovate acute whitiſh villoſe. Pedicels ſhorter than the peduncle, capillary pubeſcent one-flowered. Flowers minute, whitiſh. Calyx-leaves lanceolate, after flowering upright, rough-haired. Petals lanceolate, leſs by half than the calyx-leaves, whitiſh and diaphanous, caducous. Filament one, length of the petals: anther roundiſh, twin, yellow. Style very ſhort and thick, diaphanous. Stigma villoſe (perhaps three). Capſule roundiſh-three-cornered, retuſe, ſize of a muſtard-ſeed: cells two-ſeeded. Seeds roundiſh, ſhining.—Native of the weſtern part of Hiſpaniola, in mountain woods.

11. Plant from one to two feet high. Stem herbaceous, ſomewhat jointed, round, ſtriated, ſmooth. Branches from the ſheaths of the leaves, ſhortiſh, erect. Leaves alternate, ſeſſile, ſheathing at the baſe, cordate-ovate acute, an inch long, ſomewhat ſtriated with longitudinal nerves, ſmooth on both ſides, ſomewhat ciliate at the edge. Sheaths ſhort, ſubcylindric or ovate, ſomewhat ventricoſe, membranaceous, ſtriated, ciliate at the edge. Peduncles from the ſheaths of the terminating leaves, two or three together, commonly ſhorter than the leaves, erect, many-flowered, rough-haired. Flowers ten to twelve, in little umbels, pedicelled, ſmall: pedicels unequal, ſhorter than the peduncles. There are a few little ciliate bractes at the baſe of the pedicels. Calyx-leaves acute, browniſh-green, pubeſcent. Petals leſs than the calyx, or equal to it, ovate, white, caducous. Filaments three, ſhorter than the petals. Anthers cordate. Germ roundiſh-three-cornered. Style thick, very ſhort. Stigmas three, white-villoſe. Capſule roundiſh, acuminate, placed on the permanent calyx. Seeds ſolitary? roundiſh, flatted a little, umbilicate, hollow-dotted, black. Native of Jamaica, in mountain woods.

12. This is a ſmall herbaceous annual plant. Radicles numerous, whitiſh. Stem tender, ſheathed, jointed at the baſe, round, ſucculent: branchlets ſhort, coming out below the ſheaths of the leaves, depreſſed, aſcending, rooting. Leaves ſubſeſſile, ſheathing at the baſe, alternate, ſmall, cordate-ovate, with a very ſhort point, entire, nerveleſs, netted-veined, bright green, ſubdiaphanous. Sheaths ſhort, ſurrounding the ſtem, ciliate at the jaws. Peduncles longer than the leaves, erect, flowering at the top: flowers three to five, minute, on ſhort pedicels, cluſtered in umbellets; with two or three very minute ovate bractes, ciliate at the edge, under their baſe: pedicels bent down after flowering. Calyx-leaves pubeſcent, green except the baſe which is brown. Petals bigger than the calyx-leaves, cordate-ovate acute, white, caducous. Nectaries none. Filaments very ſhort, uniform, naked at the baſe, not hairy. Anthers twin, pellucid, with roundiſh cells. Germ roundiſh-three-cornered, pellucid. Style thickiſh. Stigma ſubcapitate, trifid, pubeſcent. Capſule three-cornered, opening at the top: cells two-ſeeded. Seeds roundiſh.—Native of Jamaica, in moiſt ſhady graſſy parts of high mountains; flowering in autumn[r].

13. This, which is the multiflora of Jacquin, ſeems to be diſtinct from that of Swartz, in having a procumbent ſtem, and ſix ſtamens to the flowers, three of which are longer and bearded.—Native of the Caraccas. Perennial[s].

14. Stem creeping at the baſe, aſcending. Leaves linear, acute, ſpreading, having coloured ſheaths ciliate with long hairs. Flowers axillary, ſolitary. Calyx three-parted, keeled, ciliate at the ends. Corolla one-petalled, funnel-form, of a deep blue purple:

[n] Hort. kew. [o] Linn. mant. [p] Vahl. [q] Jacquin. [r] Swartz. [s] Willdenow.

tube

tube twice as long as the calyx: ſegments three, ſhorter, blue. Filaments with jointed hairs. Style club-ſhaped. *Koenig.*—Rheede and other authors erroneouſly deſcribe the corolla as three-petalled. Native of the Eaſt Indies; where cattle are very fond of it. Annual[t].

15. Stem a foot high, even, woolly under the joints. Flowers in ſeveral remote whorls. Leaves under the whorls enſiform-lanceolate, a little woolly at the edge. Petals ſix; outer three lanceolate more rigid; inner three, more tender. Filaments length of the corolla, woolly at top: anthers erect. Germ ſuperior, three-ſided. Style length of the corolla, bearded at the tip. Stigma oblong, three-ſided.—Native of the Cape of Good Hope. Thunberg[u].

16. Root annual. Stems round, even, branched, diffuſed, creeping. Leaves lanceolate, recurved, even, ſheathed at the baſe with ſtriated ſheaths. Spathes two-flowered with the flowers ſeſſile, creſcent-ſhaped, ſix pairs, directed all the ſame way. Calyx ſhorter than the corolla. Petals ovate, ſeſſile, blue. Filaments hairy on the outſide with blue jointed hairs. Style club-ſhaped. Stigma tubular, crenate[x].—Native of Ceylon. Introduced in 1770, by Monſ. Richard. It flowers from july to ſeptember[y].

17. Root annual, fibrous. Stems three inches long, jointed, rooting at the joints. Leaves linear-lanceolate, hairy underneath, erect, ſeſſile, ſubciliate at the baſe: ſheath widiſh, very ſhort. Spathe terminating, cordate, folded downwards, ſubciliate at the edge; under which are two lanceolate-creſcented leaflets, the upper one ſhorter; between theſe is the flower; inſtead of a keel, between the above two leaflets, another ſpathe comes out afterwards, which is alſo ſhort, and together with its leaflets not yet viſible; and thus the ſpathe reſembles a papilionaceous flower. Corolla violet-coloured (not blue). Filaments blue, with jointed hairs globular at the tip, longer at the top. Stem green, not ruſeſcent; in other reſpects ſo like to T. criſtata, that it may be conſidered as a variety of that; but this differs from it in having the ſtamens longer than the corolla[z].

Vahl remarks, that the flowers are not only terminating but axillary.

Native of the Eaſt Indies.

18. Root tuberous, perennial. Stems ſeveral, creeping, round, jointed, from ſix to thirty-ſix inches long; beſides a tuft of three or four liliaceous, ſword-form leaves iſſuing immediately from the heads of tuberous roots, or rather their ſheaths, form a head, from which iſſue the roots and procumbent ſtems. Leaves on the ſtem linear-lanceolate, ſheathing, ſtriated, under ſide tinged with purple, downy. Spikes terminating, or from the exterior axils, one or two together, peduncled, beautifully imbricate, as in T. criſtata, with two rows of falcate, ciliate bractes. Flowers one in the axil of each bracte, ſmall, blue-purple. Corolla, ſtamens and piſtils as in T. axillaris.

19. Root fibrous, annual. Stems creeping, with their extremities erect, jointed, ſmooth. Leaves lanceolate, ſheathing; mouth of the ſheath woolly. Panicle terminating, globular, many-flowered, hairy. Flowers ſmall, blue. Calyx three-leaved, hairy. Corolla three-parted; the two upper diviſions large and ovate, the third lanceolate. Filaments ſimple, inſerted round the germ, as long as the petals, without hairs or ſwelling.—It is called Conda Amadicada by the Telingas. Both are natives of Coromandel, in moiſt vallies[a].

Swartz obſerves, that T. cordifolia much reſembles Calliſia; and he would bring C. repens into this genus, under the name of Tradeſcantia Calliſia.]

PROPAGATION AND CULTURE.

1. Virginian Spiderwort multiplies ſo faſt by its roots, as alſo from the ſeeds, if permitted to fall, that it muſt be yearly reduced, to keep it within bounds. The beſt time to remove and part the roots is in the autumn.

[2. to 14. and 16. to 19. The other ſpecies, from the Eaſt and Weſt Indies, require the heat of a ſtove, in which ſome of them may be abundantly increaſed both by ſeeds and offsets. Some of the ſpecies are annual, and can be propagated only by ſeeds; but the greater part is perennial.

N. 15. being a native of the Cape of Good Hope, requires only the protection of the dry ſtove.

TRAGACANTHA, and Tragacanthæ affinis. See *Aſtragalus.*]

TRAGIA. (*So named by Plumier, in memory of* Hieronymus Tragus, *whoſe real name was* Jerome Bock. *A German Divine and Phyſician. Leaves ſubcordate-ovate attenuated almoſt quite entire, valves of the capſules two-horned.

DESCRIPTIONS, *&c.*

1. Stem ſuffruteſcent, looſe, round, ſtinging with its briſtles: branches filiform, all directed one way, ſimple. Leaves petioled, alternate, ſerrate, bent down, nerved, hiſpid with briſtles. Stipules lanceolate, oppoſite by the ſide of the petioles; which are long and hiſpid. Racemes peduncled, axillary, ſolitary, longer than the leaves, filiform, looſe, compoſed of numerous very ſmall male flowers, on very ſhort pedicels; with minute awl-ſhaped bractes under the pedicels: and females at the baſe, pedicelled, ſolitary, larger. Calyx of the male three-leaved; leaflets coloured of a dark purple; filaments very ſhort, contiguous:—calyx of the female, five-parted; germ hirſute, ſtyle trifid, ſtigmas revolute [b].

Linneus remarks, that the ſtem twines in a direction contrary to the ſun's apparent motion; that the leaves are cordate, oblong-acuminate, ſharply ſerrate, with ſtiff hairs ſcattered over the ſurface; that the male flowers are green and trifid, the female axillary, ſolitary, on a long, jointed, incurved peduncle; and that the capſule is covered with ſtiff ſtinging briſtles, each cell marked on the outſide at the baſe with two calluſes.

Native of the Eaſt and Weſt Indies. It is very common in Jamaica, and is well known there on account of its ſharp ſtinging hairs, with which the whole plant is covered. The root is looked upon as a good aperient and diuretic; both the decoction and juice are frequently uſed among the negroes for thoſe purpoſes [c].

Cultivated by Mr. Miller in 1739.

2. Stem ſhrubby, twining, hiſpid as is the whole plant. Leaves cordate, ſerrate, acuminate, paler underneath. Spikes terminating.—The preceding ſpecies differs from this in having the leaves groſsly ſerrate, and the bractes entire. The next ſucceeding ſpecies is diſtinguiſhed by the leaves being ſharp at both ends [d].]

3. This riſes with an erect woody ſtem about three feet high, and rarely ſends out any ſide branches. Leaves oblong-lanceolate running out in very long acute points, ſharply ſerrate, alternate, cloſely covered with yellowiſh ſtinging hairs. Flowers in ſmall axillary cluſters, ſtanding ſeveral together upon the ſame foot-ſtalk; the upper ones all male, and the under female; the latter ſucceeded by roundiſh capſules, with three cells, each incloſing one ſeed. Native of the Eaſt Indies.

[Cultivated by Mr. Miller in 1759.

4. The American plant, here conſidered only as a variety of the Eaſt Indian, is probably a diſtinct ſpecies. Sloane's ſynonym, given by Linneus, belongs to Acalypha reptans [e].

5. This is an annual plant, native of Virginia. Introduced in 1778, by John Fothergill, M. D. It flowers in auguſt [f].

6. Stem erect, divided into long erect branches. Leaves narrower at the baſe. Above the diviſions of the ſtem a ſpike ariſes, with a ſingle female flower having no involucre, and many male flowers forming a ſmall ſpike [g].

Root annual, very ſlender, fibrous, blackiſh. Stem round, dark green. Leaves alternate, on ſhort petioles, ſmooth, long, paler underneath, very finely and ſlightly ſerrate. Capſule echinate or covered with unarmed ſpinules. Seeds oblong aſh-coloured [h].—The leaves in Burman's figure are rather linear than lanceolate, and he ſays they are *perfectæ linearia.* He finds fault with the figure in Hortus Malabaricus, for having the teeth at the edges of the leaves too large: and in his figure they are not diſcoverable.—Native of the Eaſt Indies.

7. Stem erect, round, hiſpid. Leaves alternate, petioled, three-parted, hiſpid: ſegments lanceolate, ſinuate. Stipules two, lanceolate, ſhort. Peduncles lateral, ſolitary, one-flowered, length of the leaves. Female calyx ſix-leaved, pectinate.—Native of Malabar. Koenig.

Two Crotons, ſuppoſed in the 13th edition of Syſtema Vegetabilium to be diſtinct ſpecies, are here united, being mere varieties [i].

8. Root annual, fibrous. Stem herbaceous, erect, a foot and half high, hairy, round: branches alternate, ſpreading, ſimple. Leaves alternate, from an inch to two inches in length, entire except that they have ſometimes an obſcure tooth or two at the baſe, pubeſcent, veinleſs, indiſtinctly nerved: petiole half an inch in length. Male flowers a little below the petiole or lateral, in a filiform ſpike, peltate half an inch in length, very ſmall: calyx three-parted; ſegments erect, converging, obovate: one filament hanging out between each ſegment of the calyx, anther globular. Female flowers below the male ſpike, nearer to the antecedent leaf, ſolitary, peduncled: calyx ſix-parted, deciduous; ſegments ovate, minute: Germ oblong; ſtyle trifid; ſtigmas ſimple. Capſule three-ſided, oblong, truncate at each end, ſmooth; valves above and below two-horned. Found in the iſland of Trinidad by Ryan.]

PROPAGATION AND CULTURE.

Theſe plants, being of no great beauty, are ſeldom preſerved except in the ſtoves of botanic gardens. Sow the ſeeds on a hot-bed early in the ſpring: when the plants are in a proper ſtate tranſplant each into a ſeparate pot, plunge the pots into a hot-bed of tanner's bark, and treat them in the ſame manner as other tender plants, which require to be kept in the bark ſtove.

Lin. ſpec. 1111. *Reich.* 3. 614. *Gron. virg.* 1. 91. 2. 113.
Radical leaves lyrate rounded, ſtem-leaves undivided.

DESCRIPTIONS, &c.

1. Root biennial, fuſiform or fleſhy tapering, abounding with milk, which is ſweet not acrid. Whole herb ſmooth and very even. Stems ſeveral, branched, eighteen inches or two feet high, leafy, round, often tinged with purple. Branches elongated into a ſimple naked peduncle. Leaves alternate, ſeſſile, ſome radical, others embracing the ſtem and branches, all broad and ſomewhat inflated at the baſe, but terminating in a long narrow point, which is flaccid or apt to hang down; very generally the margin towards the bottom is more or leſs waved or curled. Peduncles terminating, ſolitary, one-flowered, not ſwelling out at top, but of an equal thickneſs throughout.

Digitized by Google

out. Flowers large and handſome, opening at day-break, and cloſing before noon, (between nine and ten, *Linn.*) unleſs, as Mr. Relhan obſerves, the weather be cloudy. Calyx-leaves lanceolate, acuminate, flat, equal though ranged alternately or in two rows. Florets yellow with browniſh nerves, eſpecially on the upper ſide, five-toothed, the outermoſt row much larger than the reſt, varying in length, but generally as long as or longer than the calyx. Anthers brown or purpliſh. Germ pencilled or having a tuft of hairs at the ſummit. Receptacle dotted. Seed crooked, furrowed, and rugged. Seed-down radiated and feathered, ſtanding on an awl-ſhaped ſtipe or footſtalk[1].

Such, ſays Dr. Smith, is our Engliſh plant, which in ſo many reſpects agrees with the character, and even with the ſpecimen of Linneus's T. orientale, that we are not ſure of their being diſtinct; yet there can be ſtill leſs doubt of ours being his T. pratenſe. In fact, the length of the outer florets is very variable[m]. Mr. Woodward ſays, that in ſpecimens gathered in Huntingdonſhire the calyx was always exactly equal with the outer florets, but that in Norfolk it invariably exceeded them. Mr. Stackhouſe alſo remarks, that the calyx in Corniſh plants is always much longer than the florets[n]. According to Reichard, the corolla is often ſhorter than the calyx; and that it is ſometimes ſo is obſerved by Mr. Relhan. Pollich makes the florets ſhorter than the calyx or equal to it; and Scopoli on the contrary affirms, that the calyx is equal to the ray, or ſhorter than it. May not the proportion between their lengths vary at different periods of the flowering?

The whole plant, according to Withering, is ſmooth, ſtiff, ſtrong, upright: leaves very long and narrow, tapering: calyx-leaves purpliſh at the edge: anthers purple, with yellow pollen: ſeeds crooked: in the receptacle there are glandular ſubſtances in the little hollows at the baſe of each floret, which, when the florets fall, turn brown, the receptacle remaining white.

Gærtner remarks, that the receptacle is at firſt flat, but becomes a little convex. He deſcribes the ſeeds as very long, fuſiform-club-ſhaped, ſtriated, ſmooth or rugged with acute dots, whitiſh, ending in the ſtipe; the ſeed-down white and caducous, the rays chaffy, unequal, the length of the ſtipe, which is of a ſubulate-ſetaceous form, ſolid, and nearly equal to the ſeed in length.

Native of Europe and Siberia. Not unfrequent in Britain among graſs; flowering in june.

In ſome parts of England it is called Buck's-beard, from the German; and Go-to-bed at noon, from the circumſtance of the flowers cloſing about that time:—Gerarde has Joſeph's flower, from the Dutch, and Star of Jeruſalem.

Before the ſtems ſhoot up, the roots, boiled like Aſparagus, have the ſame flavour, and are nearly as nutritious[o]. Villars relates, that the children in Dauphiné univerſally eat the ſtems and leaves of the young plant before the flowers appear, with great avidity: that the freſh juice of theſe tender herbs is the beſt diſſolvent of the bile: and that both animals and children invite us to make uſe of this remedy, which relieves the ſtomach without danger, and without introducing into the blood an acrid corroſive ſtimulant, as is frequently done by ſalts, ſoaps, and reſins, which are uſed for this purpoſe.

Mr. Miller names our common Goat's-beard *T. minus*, and comparing it with his *pratenſe*, which is the *major* of Jacquin, he ſays that] the lower leaves are almoſt as long as in that, but not more than a third of the breadth, of a deep green colour, and ending in acute points; that the ſtalks riſe about a foot high, and ſuſtain one yellow flower at the top, not more than half ſo large as the other; that the calyx is longer than the ray of the corolla, and the ſeeds much ſmaller than thoſe of the other.

[2. Root biennial. The whole plant ſmooth and milky. Stem round, upright, branched at all the axils from the very root. Leaves ſeſſile, having innumerable very ſmall teeth along the edge, ſcarcely waved; the lower and larger ſtem-leaves two inches wide at the baſe, and near a foot in length. The ſubdiviſions of the branches are terminated in one-flowered peduncles. Flowers ſpreading very much, nod towards the ſun; they open nearly at ſun-riſe, and cloſe about ten o'clock, and ſo continue for three days, during which the florets ſucceſſively expand: the firſt day, the outer row of florets only is expanded, and thus at firſt the flower is compoſed of a ſingle ray, with the interior florets converging into an upright cone. The whole corolla during this time is augmented; ſo that if we are to determine the ſpecies by the relative length of the calyx and corolla, we ſhould wait till the flower is in perfection, that is, when all the florets are expanded: for this is the caſe in all the ſpecies. Corollas five-lined, five-toothed, for the moſt part white on both ſides: but ſome are roſe-coloured with red ſtreaks, others yellow with purple ſtreaks, and of different ſhades. Hence the trivial name of *mutabilis*. Anthers yellow with ſtreaks brown at top. Stigmas yellow. Seeds ſmooth, aſh-coloured. Down ſtiped, like a ſpider's web, with five longer briſtles. It flowers from the end of may to july. Jacquin had the ſeeds from Pallas, it is probably therefore a native of Siberia.

3. Root fuſiform, biennial, the thickneſs of a finger. The whole plant is milky. Stem erect, from four to ſeven feet high, clothed with a ſhort wool, which falls off, and it is then ſmooth. Lower ſtem-leaves a foot long and more, ſcarcely an inch wide at the baſe, not waved; thoſe on the branches are very much waved, and are often rolled back at the ends: all lanceolate-linear, acute, rugged at the edges, ſeſſile or embracing: the branchlets end in one-floweted peduncles. Calyx-leaves from eight to thirteen. Corollets ſulphur-coloured on both ſides, often paler. Anthers browniſh. Styles yellow. Seeds appear extremely muricate when examined with a magnifier, and are aſh-coloured. Seed down cobwebbed, with five longer briſtles, on a very ſhort ſtipe. It flowers in june and july. Jacquin has often had the ſeeds under the name of T. orientalis; but Tournefort attributes a very large flower and deep yellow colour to that, and Linneus ſays it is larger than that of the common ſort[p].

4. This differs from T. pratenſis in having a larger flower; the calyx where it is turned back as it were broken; the ray of the corolla yellow underneath, not brown ſtriated; and the anthers yellow, not brown.—Native of the Levant[q].

5. Root biennial, long, tapering or round-fuſiform, that and the whole plant abounding with a ſweet milky juice, which ſoon turns to a brown reſin, from the evaporation of its watery particles. Herb ſmooth, glaucous, about four feet high. Stem round, erect, branching, leafy. Leaves lanceolate, ſcarcely waved, ending in a tapering ſtraightiſh point. Flowers ſolitary, terminating, the ſtalk which ſupports them tapering from the calyx downwards. Calyx-leaves equal, linear-lanceolate, almoſt twice as long as the corolla; which is of a dull purple hue. Anthers darker. A few hairs may be obſerved at the orifice of the tube of each floret. The feathery crown of the ſeed, at firſt ſeſſile, is ſoon raiſed on a long taper ſtalk, as in the other ſpecies[r].

Mr. Woodward remarks that the leaves on the ſtem are ſhorter than in the pratenſis, being ſcarcely longer than the internodial ſpaces:—and Dr. Smith, that the flowers cloſe early in the day.

Native of ſeveral parts of Europe. In England not very common. Gerarde ſays, it grows only in Lancaſhire, upon the banks of the river Chalder, two miles from Whawley. Dr. Gunthorp found it in many parts of Cornwall. *Merret's pinax.*—Mr. Nicholſon in fields about Carliſle and Roſe Caſtle in Cumberland.—Mr. Blackſtone in marſhes below Woolwich, and near Edmonton.—Mr. Sowerby and

Mr.

Digitized by Google

Mr. Dawſon Turner, in meadows below St. Vincent's rocks, Briſtol.—According to Mr. Woodward, it is not unfrequent in upland paſtures [a].]

It is cultivated in gardens by the name of Salſafy. The roots boiled or ſtewed, have a mild ſweetiſh flavour. Some perſons cultivate it for the ſtalks, which are cut in the ſpring, when they are four or five inches high, which are dreſſed like Aſparagus, in the ſame manner as the common ſort. The ſtalks of this are much longer and more tender than that. [It is not much cultivated for the table at preſent. Neither Gerarde nor Parkinſon hint that this plant was kept in our gardens in their times for any other purpoſe but for the flowers: but they recommend the common yellow ſort as excellent for the table.

7. This reſembles the preceding, but is ſcarcely a foot high, whereas that ſometimes attains ſix feet. The leaves are villoſe at the baſe, but become ſmooth by age. Calyx five-leaved. Flowers violet, of two rows only, but in the middle rather yellow.—Native of Italy and the South of France. Biennial [b].

Villars ſays, the ſtems are ſhort and little branched, the leaves narrow, procumbent, and villoſe at the baſe, the flowers ſmall, blue with a little yellow at the end of the rays, the ſeeds a little flatted, toothed on the ſides, terminated by a ſupport widened at its upper part, where the ſeed-down is inſerted on a brown depreſſed circle. Biennial.

Gouan found it a cubit in height, and obſerves that the calyxes have from five to ſeven leaves.

It was cultivated in 1739 by Mr. Miller [c].

8. Root biennial. Size of T. porrifolius, but the whole plant is pubeſcent with white villoſe hairs, eſpecially the ſtem, and the leaves underneath more copiouſly. Peduncles cylindrical. Calyx nine-leaved, not imbricate. Corolla paler yellow than the reſt, eighteen-rayed. Anthers browniſh. The plant finally puts forth flowering branches its whole length from the axils of all the leaves, whence it becomes corymbed. The flower when expanded nods a little.—Native of Spain and Siberia [d]: and according to Krocker, of Sileſia.

9. Root perennial, thick and ſucculent. Stems about a foot high, ſometimes leſs. Leaves large, thick, villoſe, toothed and ſinuated; the upper ones often entire. From the centre of the root-leaves, which ſpread in a roſe, riſes a naked thick flower-ſtalk, villoſe and thicker in the upper part, where it terminates in a very large flower, of a pale yellow or ſulphur colour. Calyx of one piece, cut at the upper part into ſeveral ſegments. Florets large, pale yellow above, red or purple underneath. Seeds rugged, flatted, ſupported on a ſmall pedicel, and terminated by a ſeed-down, on a long, round ſtipe ſwollen at the baſe and jointed with the ſeed [e].

According to Linneus, the ſtem is very ſhort, the leaves tomentoſe and rugged, not toothletted, the corolla purple underneath, the florets yellow with purpliſh tips.]

Mr. Miller ſays, the leaves are ſix or ſeven inches long and two broad, indented on their ſides, and the flower-ſtalk ariſing immediately from the root is a foot in length, and ſupports one large ſulphur-coloured flower.

[Gærtner deſcribes the ſeeds as ſhort in proportion to the ſtipe, oblong, compreſſed, muricated with three or four rows of acuminate tubercles, and whitiſh: the ſtipe thicker than the ſeed and three times as long, awl-ſhaped, indiſtinctly ſtriated and wrinkled, compreſſed, hollow within, not cruſtaceous as in T. picroides: ſeed-down caducous, rufous or red-purple.

Native of Spain, the South of France, and Barbary.—Cultivated in 1739 by Mr. Miller. It flowers from june to october [f].

10. This is an annual plant, with hollow tender ſtems little branched. Leaves rude, of a dark green, covered with long ſtiff hairs. Calyx of one piece like the preceding, but rude and rough with hairs.

[a] Smith brit. and Withering. [b] Linn. mant. [c] Hort. kew. [d] Linn. ſpec. [e] Villars. [f] Hort. kew.

Flowers yellow. Seeds jointed, on one ſtipe terminated by another, as in the preceding ſpecies [a].]

Mr. Miller ſays, it is very like the Sowthiſtle in ſtalk and leaf, but that the calyx is prickly.

[Gouan remarks, that this ſpecies varies in ſhady places, like the Sowthiſtle, with the leaves entire or runcinate, the root-leaves often obovate and entire; the ſtem ſcarcely branched and low, ſo that it might eaſily be taken for the aſper; but it differs manifeſtly in having the ſtem-leaves always dilated at the baſe.

Gærtner deſcribes the ſeeds as differing ſomewhat in ſhape; thoſe of the ray being curved inwards, thoſe of the diſk ſtraightiſh: both compreſſed at the baſe, either muricated on both ſides with a triple row of ſcalelets ſpreading horizontally, or crenulate only at the upper margin. Stipe much thicker than the ſeed, curved, inflated below, hollow, attenuated and filiform above, rugged all over with ſharp points, together with the ſeed itſelf of a red ruſt colour. Seed down ſilky white, caducous.

From this ſingularity of a double or jointed ſtipe, Scopoli has ſeparated this and the preceding ſpecies from the Tragopogons, under the name of *Urospermum* [b].

Native of the South of Europe. Cultivated in 1683, by Mr. James Sutherland. It flowers in july and auguſt [c].

11. According to Gouan, this ſpecies varies ſo much in open expoſed ſituations, as to have the appearance of a different ſpecies; from which it differs eſpecially in having the ſtem-leaves wider at the end, narrower at the baſe; which in T. picroides are more dilated, embracing and toothed, wider at the end. The calyxes are prickly with hiſpid hairs in both [d].

Native of Montpelier. Introduced in 1774. by Monſ. Richard. It flowers in july and auguſt. Annual [e].

12. Leaves long, ſmooth, quite entire. Scapes one-flowered, entirely leafleſs, pubeſcent at the top. Seed-down hairy.—Native of Virginia.

13. The ſcapes in this have a leaflet in the middle, but ſcarcely apparent; and they bear a ſingle flower. The figure in Rauwolff (it. 217.) rather repreſents this plant than Erigeron tuberoſum.—Native of Paleſtine.

14. Root-leaves very many, ſmooth. Stems almoſt naked, upright, ſtiff, with one or two lanceolate embracing leaves on them; and few branches: theſe are terminated by three peduncles, at the baſe of which are two lanceolate oppoſite leaves, with one ſmaller. Calyx divided into twelve leaves to the baſe: equal, ſhorter than the corolla. Florets deep yellow. It has the habit of Arniea Gerberia. The ſeed-down is not feathered, but ſimple, nor is it ſtiped. It has the ſtature of Hyoſeris; the calyx of Tragopogon, and the ſeeds of Hieracium.—Native of Virginia and Canada [f].]

PROPAGATION AND CULTURE.

Theſe plants are propagated from ſeeds, which ſhould be ſown in april upon an open ſpot of ground, in rows about nine or ten inches diſtance, and when the plants are come up, they ſhould be hoed out, leaving them about ſix inches aſunder in the rows. The weeds ſhould alſo be carefully hoed down as they are produced, otherwiſe they will ſoon overbear the plants and ſpoil them. This is all the culture required, and if the ſoil be light and not too dry, the plants will have large roots before winter, at which time the Salſafy, whoſe roots are eaten at that ſeaſon, will be fit for uſe, and may be taken up any time after their leaves begin to decay; but, when they begin to ſhoot again, they will be ſticky and not fit for uſe; but many perſons cultivate this ſort for the ſhoots.

The common yellow ſort, whoſe ſhoots are ſold in the market, will be fit for uſe in april or may, according to the forwardneſs of the ſeaſon. The beſt time to cut them is, when their ſtems are about four inches long, for if they ſtand too long, they are never ſo tender as thoſe which are cut while young.

[a] Villars. [b] Gærtner. [c] Hort. kew. [d] Gouan illuſtr. [e] Hort. kew. [f] Linn. ſpec.

Some

Digitized by Google

Some people, in cultivating theſe plants, ſow their ſeeds in beds pretty cloſe, and when they come up, they tranſplant them out in rows at the before-mentioned diſtance; but, as they form a tap-root, which abounds with a milky juice, when the extreme part of their roots are broken by tranſplanting, they ſeldom thrive well afterward; therefore, it is by far the better way to make ſhallow drills in the ground, and ſcatter the ſeeds therein, as before directed, whereby the rows will be at a due diſtance; and there will be nothing more to do than to hoe out the plants when they are too thick in the rows, which will be much leſs trouble than the other method of tranſplanting, and the plants will be much larger and fairer.

DESCRIPTIONS, *&c.*

1. The immerſed leaves are multifid and capillary, like thoſe of Myriophyllum: the floating leaves are rhomb-ſhaped, with bladdery petioles. The four leaves of the calyx ſurround the germ, two at the ſides and two at the angles of it, whence the horns of the fruit[g].

Root round, very long, brown, putting forth oppoſite, round, green roots, which have oppoſite round fibrils, cloſely placed, ſo as to reſemble pinnate leaves, (and they are the immerſed leaves of Linneus.) Petioles round, long, near the leaves inflated into a tumour, and then again round. From the axils of the leaves a ſingle peduncle: this and the petioles villoſe. Calyx-leaves at firſt converging, afterwards ſpreading. The floreſcence is completed within the converging calyx. Petals white, pellucid, gaſhed and emarginate, with very ſhort purple claws below the nectary; which is a permanent yellowiſh, then white, finally green membrane, plaited like a ſtar, with eight angles. Anthers yellow, twin, large. Stigma hollow, round, red, perforated[h]. Nut inferior, coriaceous, hard, ſubturbinate, rhombed, armed in the middle with four very ſtrong ſpines curved in upwards, indiſtinctly grooved, not opening, but germinating through a hole in the top, which is cloſed by a thin pellicle and converging briſtles. Receptacle of the ripe ſeed none, but the two young germs have a very ſhort umbilical chord deſcending from the upper part of the partition, and keeping them ſuſpended. Seed ſingle, fleſhy, large, the ſize and form of the internal cavity of the nut. It has two cotyledons, one very large and thick, forming almoſt the whole bulk of the embryo; the other very ſmall, in ſhape of a roundiſh ſcalelet at the baſe of the radicle: ſo that this plant, like the Nelumbo, is in a ſort of middle ſtation between the monocotyledones and dicotyledones; for though there be a ſecond lobe in the embryo, it is very minute, and does not make its appearance in the germination[i].

The nuts are eſteemed farinaceous, nouriſhing and pectoral. The ſkin with the ſpines being removed, there is a white ſweet kernel within, ſomewhat like a cheſtnut. They are ſold in the market at Venice under the name of Jeſuits nuts. At Vercelli they are called Galarin, and are much eaten there by the children and common people[k]. Pliny ſays (l. 22. c. 10.) that the Thracians made them into bread. According to Thunberg, the roots are commonly boiled in broth in Japan, though the taſte is by no means pleaſant.

Native of Europe and Aſia.—Introduced in 1781, by Daniel Charles Solander, L.L.D. It flowers from june to auguſt, and is annual[l].

Villars condemns the figures of Tragus, Cordus, Lobel, Dodonæus, Matthiolus, &c.

This ſingular plant was called by old writers *Tribulus*, but this name being aſſigned to another genus, Tournefort altered it to *Tribuloides*; but that not being a legitimate name, according to Linneus's idea, he entitled it *Trapa*.

2. The nut of this is woody-coriaceous, black-brown, inverſely pyramidal, rhombed, below beautifully areolated with ribs and grooves, branched, ocellated, and variouſly confluent, terminated at top with a four-cornered head, radiantly ſtriated, having a round hole punched through it, armed on each ſide with a very thick horn, ſpreading horizontally and moderately curved back. Cell one, correſponding in form to the body of the nut[m].

Though the preceding ſpecies varies with three and even two horns, yet this is not a variety of it, for in that the horns are always acuminate, whereas in this they are obtuſe and have quite a different appearance[n]. —Native of China.

Loureiro has given two ſpecies of Trapa, which he names *cochinchinenſis* and *chinenſis*. They are certainly diſtinct from the European plant; but the latter is probably the ſame with our ſecond ſpecies, and he himſelf allows that the former may be only a variety of the latter.

The Chineſe cultivate the plant in their moſt barren marſhes for the food of the inhabitants[o].

TREMELLA. (*Dimin. from* tremo, *to tremble.*)
Lin. gen. Schreb. n. 1669. *Dill. muſc.* 41.
Cryptogamia Algæ.

GENERIC CHARACTER.

Subſtance uniform, membranaceous, gelatinous, pellucid.

Eleven ſpecies are enumerated in the fourteenth edition of Syſtema Vegetabilium: nine by Relhan: and nineteen by Withering.

Tremella Noſtoc is not uncommon after rain in graſs fields, and on gravel walks; and is vulgarly ſuppoſed to be the remains of a meteor or fallen ſtar. It is ſomewhat gelatinous, conſiſting of ſeveral leaves variouſly lobed and waved, ſlightly adhering to the ground by a central root; the ſubſtance very thin. It varies in colour, but is uſually ſome ſhade of olive. When dry, it is of a dark brown and brittle. Micheli deſcribes the ſeeds as lying in the form of little ſtrings of beads coiled up within the folds of the plant, and only to be diſcovered by the microſcope [p].

This and three other ſpecies, viz. granulata, meſenterica, and Sabinæ are figured in Engliſh Botany.

Tretorrhiza. See *Gentiana Cruciata.*

TREWIA. (*So named by Linneus in honour of Chriſt. Jac. Trew, phyſician at Nurimberg: born* 1695, *died* 1769. *Author of numerous papers in the German Acts, and of a ſplendid work entitled* Plantæ Selectæ, *with coloured figures from Ehret's drawings,* 1750, &c.)

DESCRIPTION, &c.

This is a lofty tree, with a trunk as thick as a man can embrace, covered with an aſh-coloured bark. Leaves on long round petioles, a ſpan and more in length, and almoſt two hands wide, oblong-ovate, cordate, attenuated at the point, thin and ſoft, duſky green on the upper ſurface, but brighter on the lower. Flowers on round pale-green peduncles, axillary, of an herbaceous colour, void of ſmell [q].—Native of the Eaſt Indies.]

Flowers ten-ſtamened two-ſtyled.

DESCRIPTIONS, &c.

1. This ſends out many trailing branches which lie flat on the ground, ſpreading two feet or more each way, and having much the appearance of Purſlane; with fleſhy ſucculent leaves almoſt oval: the flowers come out from the joints of the ſtalks, they are ſomewhat of a purple colour, not much unlike thoſe of Purſlane, and are ſucceeded by capſules having two horns, with one cell incloſing eight or ten ſeeds.

[Stems depreſſed, ſubdichotomous, jointed, even, pubeſcent on the upper ſide. Leaves oppoſite, petioled, oval, obtuſe, quite entire with a red margin: one of the leaves always leſs than the other. Petioles two-toothed, ſhorter than the leaf. Flowers axillary, ſeſſile, five-leaved, oval, compoſed as it were of calyx and corolla together; under them two awl-ſhaped, permanent bractes. Filaments ſix to ten, ſhorter than the calyx. Anthers oval, twin. Germ half inferior, retuſe, two-horned. Style length of the flower. It is

[p] Withering, 4. 80. ed. 3. [q] Rheed. mal.

Digitized by Google

is an annual plant, native of Jamaica and Curaſſao[r].] Mr. Miller ſays, it grows naturally in moſt of the iſlands in the Weſt Indies, and is often a troubleſome weed there.

[Linneus remarks, that there is ſcarcely any genus more irregular than this: ſo it is, according to his arrangement; and ſo it muſt be when we aim at forming natural genera in an artificial ſyſtem.

2. Stems branched, procumbent, diffuſed: branches filiform, ſmooth, round, jointed. Leaves oppoſite, oval, quite entire, veinleſs, thickiſh, ſhorter on one ſide, one of them ſmaller than the other, as in the congeners. The ſtem and leaves are beſet with pellucid bladders. Petiole length of the leaf, two-toothed at the baſe. Flowers alternate, ſmall. Calyx five-cleft[s].—Native of Arabia and the Eaſt Indies.

3. This is an annual plant, with the ſtem a foot high, round, erect, ſomewhat rugged. Leaves oppoſite, petioled, elliptic, bluntiſh, quite entire, from upright ſpreading, oleraceous. Branches alternate, ſhorter. Flowers axillary, from every other axil, between the branch and the ſtem: ſubſeſſile, many, heaped; pale within, greeniſh without. Calyx bell-ſhaped, five-parted, purpliſh within, permanent; ſegments lanceolate. Filaments five, briſtle-ſhaped, erect, diſtant, length of the corolla. Germ ſuperior, very blunt, red. Styles two, length of the germs, recurved, longitudinally pubeſcent above[t]. Capſule ovate, retuſe at top and defended by two compreſſed diſtant horns, having a longitudinal groove on each ſide, two-celled, cut round a little above the baſe, the upper valve much longer than the lower. Seeds in each cell two, rounded kidney-form or beaked, lenticular or indiſtinctly angular, wrinkled, dark-coloured; faſtened one above the other in a vertical poſition to the partition on each ſide. Linneus ſpeaks of many ſeeds, but perhaps that is in ſome other ſpecies; in this certainly there are not always even two[u]. Gærtner never could obſerve four cells, as mentioned by Adanſon, or a ſingle one only as Linneus, in his genera, deſcribes.—Native of Arabia.

4. This is a branched and very ſmooth little ſhrub: branches ſpreading, jointed: joints a little thickened at top, dotted with brown, aſh-coloured below. Leaves oppoſite, ſeſſile, fleſhy, round, marked with two lines; the point pungent: ſometimes there is a bundle of leaves in the axils. Stipule on each ſide ovate, acute, three times ſhorter than the leaves, pellucid. Flowers terminating the branchlets, four or five, ſeſſile, with pellucid bractes interpoſed between them. Calyx five-cleft, tubulous: ſegments linear, membranaceous at the edge, obtuſe. Filaments ten at the baſe of the ſegments, five only alternately antheriferous. Germ oblong: only one ſtyle: ſtigma acute[x]. Vahl had an opportunity of ſeeing only the unripe fruit, in which he obſerved that the ſeed was covered with a membrane ſeparating with the ſtyle; there is therefore another covering beſides the indurated calyx. The calyx alſo and ſtipulation being the ſame as in the other ſpecies of Trianthemum, he has rightly reduced this plant to that polymorphous genus. He remarks, that there may alſo ſometimes be two ſeeds one above the other, for although in the fruit which he examined there was only one, yet it filled only half the cavity, the remainder being empty.

Native of the kingdom of Tunis:—found in the deſert near Cafsa by Desfontaines; who adopts Forſkal's name, and ſeparates it from the Trianthemas, notwithſtanding Vahl's reaſons given above. He marks it as annual, which muſt be a miſtake.

5. 6. Natives of the Cape of Good Hope; where they were found by Thunberg[y].

7. Annual. Herb the ſtature of Glinus. Stem herbaceous, diffuſed alternately. Leaves oppoſite, petioled, elliptic, quite entire, ſmooth. Petioles membranaceous on each ſide. Bractes membranaceous. Flowers axillary, on ſhort peduncles. Calyx five-leaved, permanent; leaflets oval, membranaceous at the edge. Filaments ten or thereabouts, the length of the calyx. Anthers roundiſh. Germ ſuperior, retuſe. Styles two, filiform, patulous. Stigmas obtuſe.—Native of the Eaſt Indies[z].

Is this Trianthema diffuſa, n. 2. of Miller's Dictionary, which he ſays,] grows in the Eaſt Indies, and has ſucculent diffuſed ſtalks, near two feet long, with oval leaves, leſs ſucculent than thoſe of the firſt. The flowers are white, and are produced in cluſters ſitting cloſe to the ſtalks: they are ſucceeded by capſules containing ſeveral ſeeds.

PROPAGATION AND CULTURE.

Sow the ſeeds on a good hot-bed in the ſpring, and when the plants are fit to remove, plant them on another hot-bed, to bring them forward, otherwiſe the ſeeds will not ripen. In june they may be tranſplanted into a warm border, where they will grow until the froſt in autumn kills them.

DESCRIPTIONS, *&c.*

1. This is an annual plant, with pretty thick, compreſſed, channelled ſtalks, which trail upon the ground, and are near two feet long. Leaves pinnate, oppoſite; of three or commonly four pairs of ſmooth ſeſſile leaflets; the outer of which are largeſt. Flowers axillary: petals large, yellow. They have an agreeable odour; and are ſucceeded by roundiſh prickly fruit, ending in a long point.—Native of Jamaica, and ſome of the other iſlands in the Weſt Indies.

[Browne ſays, it grows in all the paſtures of Jamaica, is frequently gathered with other fodder-plants, and fed upon indiſcriminately by all ſorts of cattle.

It was cultivated by Mr. Miller in 1739, and flowers in june and july [a].

2. Stems aſcending, long, round, hairy, jointed. Leaves oppoſite, (except the uppermoſt, which are alternate,) petioled, one ſmaller than the other: leaflets oval-oblong, ſharpiſh, hairy on each ſide. Petioles alſo hairy. Each leaf is accompanied by a lanceolate ſhrivelling ſtipule. Peduncle from the alternate axils, or that of the ſmaller leaf, (together with a branchlet,) one-flowered, hairy, ſhorter than the leaves. Fruit angular, hairy. Native of Ceylon [b].]

3. This has a ſlender, fibrous, annual root, from which ſpring four or five ſlender ſtalks, ſpreading flat on the ground; they are hairy, and extend two feet and a half in length. At each joint are pinnate leaves, compoſed of ſix pairs of narrow hairy leaflets, almoſt of equal ſize, thoſe on the lower part of the ſtalk ſtand alternately, but towards the top they are oppoſite. Flowers axillary, on ſhort peduncles, compoſed of five broad obtuſe yellow petals. They appear in june and july; and are ſucceeded by roundiſh, five-cornered, prickly fruit, which, when ripe, divides into five cells, each containing one or two ſeeds, which ripen in auguſt and ſeptember.

[Leaves oppoſite, abruptly pinnate: leaflets ten to fourteen, ovate-oblong, quite entire, obliquely cut out at the baſe. Stipules in fours, ſmall, lanceolate, deciduous. Flowers ſolitary, on ſhort pedicels. Calyx villoſe, deciduous: ſegments ovate-lanceolate. Petals obovate. Style none or very ſhort. Stigma obtuſe, thickiſh, five-grooved. Capſules five, aggregate, cruſtaceous, bony, wedge-ſhaped on one ſide, convex on the other, muricate with rigid, awl-ſhaped, unequal, diverging prickles, commonly four in number; three or four-ſeeded, in as many obliquely tranſverſe parallel cells. Seeds ſmall, oblong, ſubcylindrical, obtuſe in front, very acute behind [c].

Gærtner deſcribes the fruit as compoſed of five nuts, united into a ſubglobular whorl, wrinkled and tubercled, armed above the baſe with four rigid prickles, which are ſtraight and bent down; thence cuneiform-compreſſed, and merely wrinkled: they are of a pale ſtraw colour, and four-celled, but valveleſs; the cells are tranſverſe, diſpoſed in a longitudinal row. Seeds ſolitary, of a parallelopiped form, flattened a little, remarkably acuminate in front, but truncate behind, marked with a little brown ſpot like a wart, pale ſtraw-coloured; they are faſtened to the central angle of the cells.

Native of moſt of the hot and temperate parts of the world; as the South of Europe, Barbary, Siberia, the coaſt of Coromandel, China, Cochinchina, and the Weſt Indies. Browne ſays, it is common about Kingſton in Jamaica; and is planted in many gardens there for the ſake of its flowers, which have an agreeable ſmell. The fowls are obſerved to feed much on them, and it is thought to heighten their flavour, as well as to contribute to fatten them. They call it Turkey Bloſſom. See n. 4. The name in French is *la Croix de Chevalier.*] Our Engliſh appellation of *Caltrops* is taken from the form of the fruit, which reſembles the machines that are caſt in the way to obſtruct an enemy's cavalry. [The Greek and Latin names have the ſame origin. The *tribula* or *tribulum*, which was uſed for threſhing, or rather rubbing out corn, is derived from τριβω, *tero*, and has the firſt ſyllable long; whereas the name of this plant has that, as well as the ſecond, ſhort.

The common Caltrops was cultivated by Gerarde in 1596 [a]. He ſays that he found it growing in a moiſt meadow adjoining to the wood or park of Sir Francis Carew near Croyden; but it is not indigenous of England.] In the South of France, Spain and Italy, it is a common weed on arable land, and is troubleſome to cattle, by the prickly fruit running into their feet.

4. This has a perennial woody root, from which ſpring out many hairy, jointed, trailing ſtalks, near two feet long. At each joint are two pinnate leaves, which differ greatly in ſize, one being compoſed of eight, and the other only of four pairs of leaflets. Peduncles axillary, hairy, near two inches long, ſuſtaining one pale-yellow flower, compoſed of five large petals, with narrow tails, but very broad and rounded at their points. Fruit roundiſh, armed with very acute ſpines.

Native of South America, and the Weſt India iſlands. Houſtoun found it at the Havanna. [Mr. Miller cultivated it before 1733. According to Swartz, the plant which Browne ſuppoſed to be the *terreſtris*, is this ſpecies. Perhaps the ſame miſtake may have been made by other writers; for it rarely happens that any plant grows ſo generally wild as that is ſaid to do.]

PROPAGATION AND CULTURE.

3. Sow the ſeeds in autumn on an open bed of freſh light earth, where the plants are deſigned to remain; for they do not bear tranſplanting very well, unleſs whilſt they are very young. In the ſpring carefully clear them from weeds; and thin them where they come up too cloſe. In june they will begin to flower; and their ſeeds will ripen in auguſt and ſeptember. If theſe be permitted to ſcatter, the plants will come up the following ſpring, and maintain their place, if they be not overborne with weeds.

1, 2, 4. The other ſorts being natives of hot countries, are very tender, and the ſeeds muſt be ſown on a hot-bed early in the ſpring. When the plants come up, tranſplant each into a ſeparate pot, filled with rich light earth, plunge them into the tan-pit, and treat them in the ſame manner as other tender exotic plants; being careful to bring them forward as early as poſſible in the ſummer, otherwiſe they will not perfect their ſeeds in this country.

4. The laſt ſort will live through the winter, if it be plunged in the bark ſtove. The following ſummer it will flower earlier, and there will be more time for the ſeeds to ripen.

Crantzia lævigata. *Swartz prodr.* 38. *Vahl ſymb.* 2. 99.

DESCRIPTION, *&c.*

This is a branching ſhrub, two or three feet high. Branches almoſt ſimple, long, ſpreading, four-cornered, leafy, even. Leaves on ſhort round petioles, oppoſite, diſtich, ovate-lanceolate, acute, convex, quite entire, veined above, marked with lines at the edge, veinleſs beneath, ſtiffiſh, very ſmooth. Flowers in ſimple, axillary, oppoſite umbels; the common peduncle four-cornered, three times ſhorter than the leaves. Of the males there are from four to eight oppoſite pedicels, approximating in form of an umbel, a quarter of an inch long, one-flowered, deciduous. There are two very ſmall whitiſh bractes at the baſe and in the middle of the pedicels. Female flower larger: ſtyles three, ſometimes but rarely four. Capſule the ſize of a large pea; the valves burſting with a ſpring. Seeds black, ſhining, girt with a membranaceous whitiſh aril.

This genus ſhould be placed between Cicca and Buxus. It is very nearly allied to the latter; but differs in having no corolla, in the form of the filaments and ſtigmas, and in the aril of the ſeed; alſo in its peculiar infloreſcence.

Native of Jamaica, in mountain coppices in the weſtern parts of the iſland; flowering in the ſpring months[e].

DESCRIPTIONS, *&c.*

1. This tree riſes about twenty feet high, with a ſtraight trunk, covered with an almoſt ſmooth grayiſh or light brown bark, having ſome white ſpots on it. About ſeven feet or more from the ground it ſends forth ſeveral branches, the ends of which have a few unequally pinnate leaves, the rachis of which is about three inches long: leaflets oppoſite, an inch and three quarters broad near the pedicel, which is an eighth of an inch in length; they are almoſt an inch aſunder, of a dark green colour and ſmooth. The ends of the twigs are branched into ſeveral green ſtalks, two inches long, which, juſt at the bottom are branched into others, ſuſtaining ſeveral whitiſh-green flowers, with purple-headed ſtamens.—Native of Jamaica; plentifully between Paſſage-Fort and St. Jago de la Vega[f].

2. This is a ſmall tree, ten feet high, or much lower, with an upright ſtem, and divided into very few branches. (Sloane ſays it has ſeveral trunks as thick as one's arm, by which it riſes to twenty feet in

[f] Sloane.

Digitized by Google

height; without any branches, and is covered with a reddiſh-brown ſmooth bark.) Leaves ſmooth or ſomewhat hairy, a foot long, ſcattered alternately at the ends of the branches: leaflets about ten on each ſide, the end one ſometimes wanting, lanceolate-ovate, bluntly acuminate, quite entire, petioled, two inches long, the intermediate ones gradually larger. Racemes axillary, ſolitary, three inches long whilſt in flower, but often lengthening to half a foot when fruiting: peduncles ſimple or branched. Flowers inodorous, ſmall, about thirty in a raceme. Calyx half-five-cleft, ſpreading flat, very ſmall. Petals whitiſh, ſpreading. Filaments hairy internally. Germ villoſe: ſtyle thick. Capſule browniſh, three-grooved. Seeds in the larger fruit ſometimes two in the ſame cell, lying one upon the other, or ſide by ſide [g]. According to Sloane, the leaflets are at an inch diſtance from each other, oppoſite with an odd one at the end, an inch and half long, and an inch broad in the middle, pointed at both ends, ſmooth, dark green, on pedicels an eighth of an inch in length. Fruit round, firſt green, then purpliſh, when ripe as big as a great garden pea, breaking into three membranes, expanding themſelves, each having a creſt or riſing in the middle, and ſhowing three almoſt triangular diſtinct kernels, covered over with a thin ſcarlet pulp.

This ſpecies was not diſtinguiſhed from the preceding. Mr. Miller has it under the name of Euonymus pinnatus.

Gærtner, under the name of Trichilia hirta, deſcribes the capſule as ſubglobular, rounded-three-cornered, three-celled, opening into three parts at the top, quite entire at the baſe, ſpreading out horizontally when it opens. Seeds ſolitary, or very rarely two together, ovate, beaked at top, ſomewhat berried, ſcarlet, faſtened to the central margin of the partitions, and hanging from it.

Native of Jamaica, St. Domingo and Carthagena, flowering there principally in november. The French in the Weſt Indies call it *Mombin batard* [h].

3. Branches villoſe, round. Leaflets moſtly oppoſite, on very ſhort petioles, elliptic, villoſe underneath, the outer ones larger, two inches long. Peduncles from the uppermoſt axils, ſeveral times ſhorter than the petioles. Flowers corymb-panicled, twice as large as in the preceding ſpecies. Bractes ovate, minute. Calyx five-cleft; ſegments rounded, villoſe. Petals oblong, a little narrower at the baſe, villoſe, obtuſe, twice as long as the calyx. Filaments connected into a tube, the length of the corolla, in the perfect flower eaſily ſeparating without tearing them: tube ſmooth below, above along the filaments and within villoſe. Anthers erect, oblong. Style length of the tube of the filaments. Stigma headed, as in the preceding [i].—Native of Arabia Felix, on mountains.

4. This is a tall, branching tree, with an unpleaſant fetid ſmell. Leaves pinnate, ſhining, alternate, numerous; rachis round, very ſlightly winged on each ſide, five inches long: leaflets three or two on each ſide, with an odd one, obovate, attenuated at the baſe, quite entire, very blunt, ſcarcely petioled, the outer ones gradually bigger. Racemes axillary, very ſhort. Capſules globular, green. Native of the Havannah, in mountain woods [k].

5. This is a tree of about twelve or fifteen feet in height, ſmooth, and branchy: branches horizontal: leaves pinnate with an odd one: leaflets trijugous with a ſeventh terminal: they are ovate-lanceolate, veiny, nerved, and ſmooth: racemes triennial, axillary, oppoſite, erect, ſhort, and many-flowered: petals pale or whitiſh: germ roundiſh, villoſe: capſule roundiſh, bilocular: ſeeds roundiſh, with a viſcid ſcarlet aril. Native of the Weſt Indies, flowering in february and march.

6. A tree of twenty feet high: branches ſubdivided, with a ſmooth ſtriated bark: leaves alternately pinnate, entire, ſmooth, gloſſy, with parallel nerves: racemes axillary, ſolitary, upright, many-flowered, ſtriated: flowers numerous, ſmall, of a pale colour, with a ſhort tube, and ovate, ſharp, ſpreading diviſions: nectary tubular, ſhorter than the corolla: filaments none: anthers ſubſeſſile: germ ovate: ſtyle ſhort, cylindric: ſtigma obtuſe, cornered: capſule ovate, three-valved, ſingle-ſeeded. Native of Jamaica, where it is called by the title of Muſk-wood, on account of the ſmell of every part of the plant when rubbed. Flowers in may [l].

7. Native of New Zealand.

8. Native of the iſland of Namoka [m].

9. Doubtful whether a ſhrub or a tree: boughs alternate; bark gray, variegated by fiſſures: leaves alternate, ternate, or pinnate-bijugous with an odd one: leaflets ovate, ſmooth, terminated by a ſharp point: flowers cluſtered, racemes axillary and terminal: flowers yellowiſh. Native of Madagaſcar [n].

10. This is a tree fifteen feet in height, upright, having an unpleaſant ſmell in all its parts. Wood whitiſh. Bark grayiſh brown. Branches numerous, round, irregular, ſpreading, often from the very ground. Leaves alternate, numerous, on a petiole ſcarce an inch long: leaflets wedgeform at the baſe, quite entire, very blunt, ſeſſile, the middle one much longer than the two at the ſides. Racemes axillary, very ſhort, ſix-flowered or thereabouts. Flowers ſmall: calyx bell-ſhaped, erect: petals whitiſh, erect, three times as long as the calyx. Capſules green with browniſh gray dots, at firſt perfectly globular, but afterwards three-grooved. Seeds ſolitary, convex on one ſide, angular on the other, with a ſcarlet pellicle. The negreſſes uſe a decoction of the roots to procure abortion. In Curaçao it is called *Kerſe-boom* or Cherry-tree, though it has nothing in common with that tree. The Spaniards alſo call it *Ceraſo macho* or male Cherry. It bears a great affinity to T. glabra.

Native of Curaçao, in dry paſtures, and on the neighbouring continent; flowering in april and may [o].

11. Branches villoſe-tomentoſe at the end. Leaves on a petiole the length of the leaflets, villoſe-tomentoſe, channelled above. Leaflets on ſhort pedicels, quite entire, acute, villoſe along the nerves underneath, above ſmooth and veinleſs; two inches long. Peduncles axillary, erect, longer than the petiole. Flowers in ſhort panicles, cluſtered; with a lanceolate leaflet at the baſe of each. Calyx villoſe, with the teeth rounded. Corolla villoſe, twice as long as the calyx. Native of Java [p].

12. The fruit of this plant is a three-celled berry, with one ſeed in each cell: it holds a middle rank therefore between this genus and Limonia. The branches are thorny. Native of the Eaſt Indies [q].]

PROPAGATION AND CULTURE.

Theſe trees and ſhrubs being natives of hot countries, cannot be preſerved in England but in a ſtove. They may be propagated by ſeeds ſown in pots, and plunged into a hot-bed: when the plants are fit to remove, plant each in a ſeparate ſmall pot, plunged again into the hot-bed, and ſhade them until they have taken new root. They may alſo be increaſed by cuttings during any of the ſummer months. [In their native countries they thrive beſt in a dry gravelly ſoil.

TRICHILIA GAURA. See *Guarea*.

TRICHLIS. See *Pharnaceum* and *Polycarpon*.

Lin. ſpec. ed. Willd. 2. 1224.
Ablania gujanenſis. *Aubl. guian.* 1. 585. *t.* 234.

DESCRIPTION, *&c.*

This is a tree growing to the height of fifty feet. Leaves ſcattered, coriaceous, oblong, acute, quite entire, veined, ſmooth, petioled. Corymbs few-flowered, ſubdichotomous, lateral. Native of the woods of Guiana *.

TRICHOMANES. (*Τριχομανες of Dioſcorides. From θριξ, τριχος hair, and μανια, madneſs. From the hairineſs of the Fern, and its ſuppoſed efficacy in mania.*)
Lin. gen. n. 1181. *Reich. n.* 1298. *Schreb. n.* 1635. *Juſſ.* 16.
Claſſ. 24. 2. Cryptogamia Filices.
Nat. order of *Filices* or *Ferns*.

GENERIC CHARACTER.

Fructifications inſerted into the margin of the frond, ſeparate.
Involucres urn-ſhaped, undivided, opening outwards.
Columns extending beyond the involucres, like ſtyles.
OBS. *Habit membranaceous, ſemitranſparent* *.

SPECIES.

* *With a ſimple frond.*

1. Trichomanes membranaceum.
Lin. ſpec. 1560. *Reich.* 4. 434.
Darea americana lichenoides. *Pet. muſ.* 763.
Phyllitis ſcandens minima, muſci facie, foliis membranaceis ſubrotundis. *Sloan. jam.* 1. 74. *t.* 27. *f.* 1. *Mor. hiſt.* 3. 558. *Raii ſuppl.* 53.

Fronds ſimple oblong lacerated.
2. Trichomanes puſillum.
Swartz prodr. 136.
Fronds ſimple linear gaſhed, ſhoot creeping.
3. Trichomanes criſpum.
Lin. ſpec. 1560. *Reich.* 4. 435. *hort. cliff.* 476.
Polypodium criſpum calyciferum. *Plum. fil.* 67. *t.* 86.
Darea filicis maris facie. *Pet. fil.* 103. *t.* 11. *f.* 8.
Fronds pinnatifid lanceolate: pinnas parallel ſubſerrate.
4. Trichomanes reptans.
Swartz prodr. 136.
Fronds cuneate-ovate, gaſh-pinnatifid, ſhoot creeping.
5. Trichomanes aſplenioides.
Swartz prodr. 136.
Hymenophyllum. *Smith dorſif.* 256.
Fronds pendulous lanceolate pinnatifid very ſmooth, ſegments two-lobed, lobes obtuſe, fructifications two-valved.
6. Trichomanes polypodioides.
Lin. ſpec. 1561. *Reich.* 4. 435.
Fronds lanceolate pinnatifid repand, flowers ſolitary terminating.

** *With a compound frond.*

7. Trichomanes crinitum.
Swartz prodr. 136.
Fronds ſubpinnate hairy, pinnas ovate pinnatifid, ſegments bifid, ſubdiviſions blunt, fructifications briſtle-bearing on an upright rough-haired ſtipe.
8. Trichomanes lucens.
Swartz prodr. 136.
Fronds bipinnatifid pendulous lanceolate birſute ſhining, pinnas parallel, ſegments roundiſh ſubſerrulate, ſtipe extremely birſute.
9. Trichomanes hirſutum.
Lin. ſpec. 1561. *Reich.* 4. 435. *Thunb. jap.* 339. *Lour. cochinch.* 681. *ed. Willd.* 837.

Darea tunbrigenſis minor. *Pet. muſ.* 761.
Muſcus montanus italicus, adianthi foliis. *Becc. muſ.* 2. 24. *t.* 2. *f.* 1.
Fronds pinnate, pinnas oblong dichotomous decurrent toothed.
13. Trichomanes adiantoides.
Lin. ſpec. 1561. *Reich.* 4. 436. *fl. zeyl. n.* 385. *Pluk. phyt. t.* 123. *f.* 6. (Adiantum.)
Filix non ramoſa zeylanica, foliis adianthi in modum ſerratis. *Burm. zeyl.* 97. *t.* 43.
Fronds pinnate, pinnas enſiform acuminate gaſh-ſerrate, ſerratures bifid.
14. Trichomanes fueoides.
Swartz prodr. 136.
Hymenophyllum. *Smith dorſif.* 257.
Fronds bipinnatifid ovate ſmooth, pinnas ovate, ſegments two-parted, ſubdiviſions ſerrate obtuſe, fructifications two-valved, inſerted above the baſe of the pinnas.
15. Trichomanes ciliatum.
Swartz prodr. 136.
Hymenophyllum. *Smith dorſif.* 257.
Fronds erect bipinnatifid deltoid, pinnas ovate, ſegments linear obtuſe ciliate, fructifications terminating bivalved rough-haired, ſtipe margined.
16. Trichomanes lineare.
Swartz prodr. 137.
Hymenophyllum. *Smith dorſif.* 257.
Fronds ſubbipinnate, pendulous lanceolate ſmooth, leaflets remote, pinnules linear two-parted, fructifications terminating two-valved, ſtipe capillary.
17. Trichomanes ſtrigoſum.
Lin. ſyſt. 941. *Thunb. jap.* 339.
Fronds bipinnate, pinnules rhombed hairy ſerrate, fructifications ſolitary below the ſerratures.

*** *With a ſuperdecompound frond.*

18. Trichomanes undulatum.
Swartz prodr. 137.
Hymenophyllum. *Smith dorſif.* 257.
Fronds tripinnatifid or bipinnatifid pendulous lanceolate, leaflets and pinnas alternate decurrent, ſegments linear retuſe crenulate-waved, fructifications terminating two-valved.
19. Trichomanes ſcandens.
Lin. ſpec. 1562. *Reich.* 4. 436. *Brown. jam.* 86. 3.

Frond

Digitized by Google

Frond ſuperdecompound, leaves and pinnas alternate lanceolate, ſegments of the pinnas wedge-ſhaped.

21. Trichomanes rigidum.
Swartz prodr. 137.
Fronds four times pinnatifid erect deltoid, leaflets ſpreading, pinnas lanceolate, ſegments linear gaſhed at the end, fruit-bearing cups pedicelled axillary.

22. Trichomanes polyanthos.
Swartz prodr. 137.
Hymenophyllum. *Smith dorſif.* 257.
Fronds four times pinnatifid deltoid erect, pinnas and pinnules decurrent, ſegments linear obtuſe, fructifications two-valved numerous, ſtipe margined.

23. Trichomanes clavatum.
Swartz prodr. 137.
Hymenophyllum. *Smith dorſif.* 257.
Fronds four times pinnatifid oblong-lanceolate looſe, pinnas and pinnules decurrent, ſegments linear emarginate, fructifications terminating two-valved roundiſh, ſtipe roundiſh.

24. Trichomanes canarienſe.
Lin. ſpec. 1562. *ſyſt.* 941. *Reich.* 4. 437. *Jacqu. collect.* 1. 121.
Davallia canarienſis. *Smith dorſif.* 246.
Filix ramoſa canar, &c. *Pluk. phyt. t.* 2. *f.* 2.
β. Polypodium luſitanicum. *Lin. ſpec.* 1556.
Filix luſit. polypodii radice. *Magnol hort.* 79. *ic.*
Fronds ſuperdecompound three-parted, leaflets alternate, pinnas alternate pinnatifid.

25. Trichomanes japonicum.
Lin. ſyſt. 941. *Thunb. jap* 340.
Fronds ſuperdecompound, pinnules gaſh-trifid acute.

26. Trichomanes capillaceum.
Lin. ſpec. 1562. *Reich.* 4. 437.
Adiantum capillaceum. *Plum. fil.* 83. *t.* 99. *Pet. fil.* 96. *t.* 10. *f.* 7.
Frouds ſuperdecompound, pinnas filiform linear one-flowered.

27. Trichomanes aculeatum.
Swartz prodr. 137.
Acroſtichum aculeatum. *Lin. Dict. noſtr. n.* 31.
Frond ſuperdecompound ſcandent very much branched, leaflets palmate, ſegments linear obtuſe, ſtipe prickly.

DESCRIPTIONS, *&c.*

1. Stalk flat, black, covered with hair, applying itſelf to rocks, ſtones or trees, and riſing ſeven or eight feet high, putting out at more or leſs diſtance, ſmall roundiſh membranaceous yellowiſh-green leaves. They grow ſometimes longer, having inciſures on their edges. The plant looks ſomewhat like a Moſs [b]. —Native of South America and Jamaica.

2. Native of Jamaica.

3. Native of Martinico.

4. Native of Jamaica.

5. Native of Jamaica [c].

6. Frond the length and breadth of a finger, pinnatifid almoſt to the midrib, with the lobes lanceolate, bluntly ſerrate, ſharp at the end, having a ſingle flower at the end of each lobe. The frond moreover is pellucid, with alternate veins.—Native of the Eaſt Indies [d].

7. 8. Natives of Jamaica [e].

9. The frond with the whole ſtipe hirſute with denſe very ſhort hairs, a ſpan high. Pinnas alternate, lanceolate, bluntiſh, gradually ſhorter, pinnatifid: pinnules lanceolate, crenate. Fructifications ſolitary in the notches of the pinnules [f].

According to Loureiro, it is ten inches high: pinnas oblong, obtuſe, with the upper margin obtuſely many-cleft and fruiting: fructifications marginal, ſolitary, lenticular, briſtle-ſhaped at the tip.—Native of America, Japan and Cochinchina.

10. Native of Jamaica.

11. Native of America. Mr. Hudſon has ſet this down as indigenous of England; and Linneus himſelf has referred to Ray's Filix humilis, &c. as a ſynonym to this ſpecies. That plant however is a variety of the next ſpecies, which ſee.

[b] Sloane. [c] Swartz. [d] Linn. ſpec. [e] Swartz. [f] Thunberg.

12. Roots ſlender, wiry, ſpreading very far, throwing out fibres here and there, and producing numerous upright fronds, which, when dried up in ſummer, curl backwards: their ſubſtance is extremely membranous and pellucid, appearing finely reticulated under a microſcope; their ſegments linear, obtuſe, ſharply ſerrate, and having a ſtrong ſimple central rib. The fructifications, when they occur, take place of the firſt ſegment of each pinna or general diviſion of the frond, each terminating its appropriate nerve, and pointing upwards. The involucre is of two ſlightly concave valves, ariſing from the ſubſtance of the leaf, irregularly notched and ſerrate on the margin. Between theſe is a ſhort column, beſet with ſmall round bivalve capſules, each embraced with an elaſtic ring as in the more common ferns [g].

Mr. Bolton remarks, that the pinnules are not always ſerrate or ſcolloped.—Mr. Griffith obſerves, that all the leaves produce fructifications in an open expoſure, but that in chinks of ſhady rocks they become luxuriant, aſſuming the appearance of *T. pyxidiferum*, and never bearing fructifications [h].

The bivalve involucre and ſhort column, ſo diſtinct from the urn-ſhaped undivided involucre, and long column or ſtyle of the true Trichomanes, induced Dr. Smith to eſtabliſh a new genus under the name of Hymenophyllum or Filmy-leaf, in his Diſſertation on Ferns, printed by the Academy of Turin [i]. Several other ſpecies here recited belong properly to that genus.

It was firſt diſcovered by Mr. Dare near Tunbridge, in moiſt clefts of rocks and ſtony places. It was firſt ſhewn to Mr. Ray by Mr. Newton, who in company with Mr. Lawſon, found it on Buzzard rough Cragg near Wrenoſe, Weſtmoreland, among the Moſs. Dr. Richardſon found it near Settle in Yorkſhire, and upon moiſt rocks in Wales. Found plentifully by Mr. Rand in company with Mr. Sherard, among the pebbles at Cockbuſh, on the coaſt of Suſſex [k]. On Dartmore, Devonſhire. On high mountains at the head of Winandermere, Weſtmoreland, by Dr. Smith. On rocks in a ſhady dell, very near Llanberris, by Mr. Aikin [l]. Mr. Lightfoot mentions it as common in Scotland.

There are two varieties of this: one mentioned by Mr. Bolton, with the fructifications on naked fruit-ſtalks. Its habit, as repreſented by Mr. Bolton is conſiderably different from that in Engliſh Botany; and though the latter has indeed fruitſtalks ſpringing from the midrib, they are not naked, but paſs within the ſubſtance to the edge of the leaf. Mr. Bolton found it under Dolbadon-caſtle near the lake of Llanberris, and on the rock called Foal-foot on Ingleborough, Yorkſhire.

The other variety found by Dr. Richardſon at Belbank, ſcarce half a mile from Bingley, at the head of a remarkable ſpring, and figured in Ray's ſynopſis, *t.* 3. *f.* 3, 4: is deſcribed there by Dillenius as having the root woolly and hairy; the ſtems winged, browniſh black below, but green above; the leaves thin, pellucid, ſhining, deep green; no fructifications were obſervable. Figure 4. is a young plant.

Mr. Griffith remarks, that the leaves are indiſtinctly waved or ſcolloped on their edges; that it is probably only a luxuriant variety of *T. tunbrigenſe*, their figure, texture, and whole habit, being the ſame, and differing only in ſize; that in cavities excluded from the ſun he has found ſpecimens partaking equally of *T. pyxidatum* and *tunbrigenſe*, which are figured by Bolton *t.* 2. *f.* 7.; and that he has ſeen ſpecimens according exactly with Mr. Bolton's figure, from a root which produced other ſmaller leaves, bearing fructifications.—Dr. Withering adds, that in the foreign ſpecimens which he has ſeen of the true *pyxidiferum*, the ſubſtance of the leaf is ſtrong and opaque, not at all like the ſilky tranſparency of our plant; and the fructifications are large, urn-ſhaped, ſeſſile, and brown-orange. —Our plant is the *pyxidiferum* of Hudſon and Bolton, but not of Linneus. Mr. Bolton found it in a little

[g] Engl. bot. [h] Withering. [i] Engl. bot. [k] Ray ſyn. [l] Withering.

dark

Digitized by Google

dark cavern under a dripping rock, a little below the ſpring of Elm Cragg Well [m].

13. This high and upright ſpecies of Fern riſes with a ſingle, firm, ſmooth, purpliſh ſtem. Pinnas of the leaves very ſmooth, gradually attenuated, very long, laciniate towards the baſe, each jag ſerrate-toothed, and each tooth bifid or ſometimes trifid: the top of the pinnas, which is very ſharp and ſlender, entire for the ſpace of an inch. The pinnas, the nearer they are to the root, the cloſer they are to each other, and on the lower part of the plant they are almoſt oppoſite, whereas the reſt are alternate, on the middle of the ſtem they are moſt remote, and cloſer again towards the top [n].—Native of the Eaſt Indies and of Africa.

14. 15. 16. Theſe are natives of Jamaica, and belong to Dr. Smith's genus of Hymenophyllum.

17. Stipe tomentoſe-ſtrigoſe. Frond wholly covered with thin hairs: pinnas enſiform: pinnules rhombed, ſerrate. It is very nearly allied to the Polypodiums; and differs from *Adiantum villoſum* in its ſolitary fructifications below the ſerratures.—Native of Japan [o].

18. Native of Jamaica.

19. This is a large Fern, and its numerous foliage often ſhoots above a foot from the climbing root or trunk of the plant [p].

The ſtalk is not ſo big as a gooſe-quill, roundiſh, black, covered towards the top with a ferruginous moſs, and having very many filaments or clavicles, by which it takes firm hold of the bark of trees, and riſes to fifteen or twenty feet high, turning itſelf round. It puts forth leaves at the diſtance of an inch from each other, about a foot long, and having about two inches of the foot-ſtalk naked. Pinnas ſometimes oppoſite, but moſtly alternate. Pinnules long, deeply cut in on the edges, very thin, pellucid, of a yellowiſh green colour, having ſome dark opaque ribs running through them, and a woolly hairy on them. Fructification at the end of the ſegments in a little cup [q].

Native of America; common in the woods of Jamaica.

20. Root ſcarcely villoſe. Stipe ſmooth, ſomewhat channelled in front, but with a blunt edge, not margined as in T. canarienſe. Frond lanceolate, a foot long, compoſed of alternate lanceolate leaves. Pinnas alternately pinnatifid, with wedge-ſhaped alternate ſegments, moſtly two-flowered [r].

Dr. Smith has inſerted this and the *canarienſe*, together with ſome Adiantums of Linnæus, and ſeveral new ſpecies of Ferns, in a genus which he has named *Davallia*, from Edmund Davall a Swiſs botaniſt, no leſs indefatigable than acute. The fructifications are in roundiſh ſeparate ſpots, near the margin of the frond, and are with reſpect to the veins always terminating, by no means lateral. The involucres are like ſcales, from the ſurface, diſtinct, ſeparating outwards. The habit is firm, poliſhed and compact, far unlike the tender, membranous, expanſive appearance of Trichomanes and Adiantum [s].—Native of China, where it was found by Oſbeck.

21. 22. 23. Natives of Jamaica. The two laſt belong to Dr. Smith's genus of *Hymenophyllum*.

24. Frond in three diviſions, alternately thrice compounded; its ultimate diviſions lanceolate and ſingle-flowered. It is a ſpecies of Davallia; native of the Canary iſlands, and alſo of the ſides of mountains in Portugal [t]. Cultivated in 1741 by Archibald, Duke of Argyle [u].

25. Fronds ſmooth, with a twiſted grooved ſtipe. Fructifications ſolitary on the laſt ſegments, within the margins; the covered membrane very thin, white.—Native of Japan, on the mountains, flowering from ſeptember to march [x].

26. Native of South America.

27. Native of Jamaica.

Forſter (in prodr.) has fifteen new ſpecies of Trichomanes, natives of the South Sea iſlands.

[m] Withering. [n] Burman. [o] Thunberg. [p] Browne. [q] Sloane. [r] Linn. ſpec. [s] Smith dorſif. 245. [t] Idem. [u] Hort. kew. [x] Thunberg.

The only ſpecies mentioned by Mr. Miller is the officinal Trichomanes, which does not belong to this genus, but to that of Aſplenium.

PROPAGATION AND CULTURE.

See Acroſtichum and Adiantum. Moſt of the ſpecies are ſtove plants.

TRICHOMANES. See *Adiantum*, *Aſplenium*, *Polypodium*, *Pteris*.]

TRICHOSANTHES. (*From θριξ hair, and ανθος a flower*.

Claſſ. 21. 9. Monoecia Syngeneſia.

Nat. order of *Cucurbitaceæ*.

GENERIC CHARACTER.

* *Male flowers.*

CAL. *Perianth* one-leafed; club-ſhaped, very long, ſmooth: *mouth* five-toothed, reflexed, ſmall.

COR. five-parted, growing to the calyx, flat, ſpreading: *ſegments* ovate-lanceolate, ciliate; with very long branching hairs.

STAM. *Filaments* three, very ſhort, at the top of the calyx. *Anther* a cylindrical erect body, covered on all ſides with a fariniferous line creeping up and down.

PIST. *Styles* three, very ſmall, growing to the tube of the calyx.

* *Females* on the ſame plant with the males.

CAL. *Perianth* as in the male, ſuperior, deciduous.

COR. as in the male.

PIST. *Germ* oblong, ſlender, inferior. *Style* filiform, length of the calyx. *Stigmas* three, oblong, awl-ſhaped, gaping.

PER. *Pome* oblong, three-celled; *cells* remote.

SEEDS many, compreſſed, obtuſe, coated.

ESSENTIAL CHARACTER.

Cal. five-toothed. *Cor.* five-parted, ciliate.

MALE. *Filaments* three.

FEM. *Style* trifid. *Pome* oblong.

SPECIES.

   Stem and leaves hairy, ſpikes axillary, bractes lanceolate ſerrate; pomes ovate acute.

6. Trichoſanthes tricuſpidata.
   Lour. cochinch. 589. *ed. Willd.* 723.
   Pomes ovate acute, leaves three-cuſped ſmooth many-nerved, ſtipules roundiſh thick crenate, ſpikes axillary.

7. Trichoſanthes ſcabra.
   Lour. cochinch. 589. *ed. Willd.* 723.
   Pomes roundiſh, leaves roundiſh rugged very much wrinkled, peduncles one-flowered.

DESCRIPTIONS, &c.

1. Stem obtuſely five-cornered, rough-haired, climbing by tendrils. Petioles thicker than the ſtem, rough-haired, ſubhiſpid. Leaves cordate, ſublobed, repand, tooth-

Digitized by Google

toothletted, pubeſcent, with pedate nerves underneath. Peduncles axillary, in pairs, beſides the trifid tendril. Female peduncle ſhorter, one-flowered: male peduncle longer, ſubpanicled. Corolla white with white ciliæ, ſimple at the baſe, the reſt alternately branched, longer than the corolla. Seeds like thoſe of Momordica [y]. Pome long, ſlender, acuminate at both ends, ſmooth, twiſted and convoluted, with alternate longitudinal green and white ſtripes [z].]

It is an annual; the ſtalks run to a great length, and if they are not ſupported, trail upon the ground, as Cucumbers and Melons. The leaves are angular and rough. The flowers come out from the ſide of the ſtalk, are white, and cut into many ſmall threads. The fruit is taper and near a foot long.

Native of China [and Cochinchina.—Cultivated in 1755, by Mr. Miller. It flowers in may and june [a].

2. Stems ſlender, twiſted and a little angular. Leaves on twiſted petioles with tendrils, ending in a point, ciliate at the edge, brown above, pale beneath. Flowers on oblong greeniſh peduncles, white within, with long white threads twiſted together at the edges, on the outſide pale green with browniſh veins.—Native of the Eaſt Indies [b].

3. Stem very long, climbing, herbaceous, branched. Leaves wide-cordate, crenate, the lower ones three-lobed, the upper palmate. Flowers white, ciliate, axillary. Pomes ſmooth, red or orange-coloured, five-celled, two inches long [c], the ſize of a pear. Seeds ſubtriangular, gibbous, with a tumid margin. The ſeeds are ſometimes uſed in diſorders of the ſtomach and bowels [d]: and the plant is celebrated for its virtues in Hortus malabaricus.

Native of the Eaſt Indies, Japan and Cochinchina.

4. Stems very ſlender, ſmooth, green, angular, flexile: joints about two inches diſtant, with very ſlender long tendrils, a leaf, and often a flower at each. Leaves not more than an inch in length, cut, roughiſh, with ſmall aſh-coloured ſpots and numerous dots ſcarcely viſible on the upper ſurface, on petioles an inch in length. Flowers white, fringed. Fruit in form of a pear, four or five inches long, about an inch and half thick, ſmooth, greeniſh with longitudinal ſtripes of ſomewhat a brighter colour: pulp very white and bitter. Seeds abundant, longiſh, narrow, of a duſky ſooty aſh-colour.

Native of the iſland of Dominica; annual, flowering there in december [e].

5. Stem ſuffruticoſe, very long, grooved, hairy, climbing with bifid tendrils. Leaves cordate, toothletted, veined; the lower ones palmate, the upper three-lobed. Flowers white, in long lateral ſpikes. Corolla ciliate with long curling threads. Pomes red, one-celled; with rhomboid, compreſſed, lobed, duſky ſeeds.

6. Stem ſhrubby, climbing with trifid tendrils. Leaves cordate, toothletted, ſmooth, ending in three points. Flowers white, in axillary ſpikes: with large, toothed bractes. Corolla fringed. Pomes ſmall, yellow, two-celled, two-ſeeded.

7. Stem ſhrubby, many-grooved, climbing with bifid tendrils. Leaves cordate, very much wrinkled, petioled, alternate. Flowers white, with ſhort threads. Pomes ſmall, red, twelve-lobed, five-celled; with many flat, oblong ſeeds.

The three laſt ſpecies are natives of Cochinchina [f].]

PROPAGATION AND CULTURE.

Sow the ſeeds on a hot-bed early in the ſpring; and treat the plants in the ſame way as Cucumbers and Melons.

[TRICHOSANTHES PUNCTATA. See *Feuillea*.]

TRICOSTEMA. (*From θριξ, τριχος hair, and στημων, ſtamen. Hairy-ſtamened.*)

Stamens ſhort, included.

[3. Trichoſtema ſpiralis.
Lour. cochinch. 371. *ed. Willd.* 451.
Stamens very long, ſpiral.]

DESCRIPTIONS, &c.

1. This is an annual plant, which riſes about ſix or eight inches high, dividing into ſmall branches. Leaves ſmall, roundiſh, not unlike thoſe of Sweet Marjoram, and covered with ſmall, fine, downy hairs. Flowers axillary, ſmall, purple; appearing late in auguſt; ſo that unleſs the ſeaſon proves warm, the ſeeds will not ripen in England.

[Native of Virginia and Pennſylvania. Cultivated in 1759, by Mr. Miller [g].]

2. This has an herbaceous branching ſtalk, which riſes from nine inches to a foot high. The leaves are ſhaped like thoſe of the Wild Marjoram, are a little hairy, and ſeſſile. The flowers are produced at the top of the branches, are ſmall, and of a purple colour. The flowers not appearing till the end of ſummer, the ſeeds ſeldom ripen here.—Native of Virginia.

[Cultivated in Sherard's garden at Eltham before 1732, from ſeeds communicated by Charles Dubois, Eſq. Treaſurer of the Eaſt India Company [h].

3. Stem herbaceous, four feet high, erect. Leaves ovate, acute, quite entire, tomentoſe. Flowers white-violet, in long terminating ſpikes. Stamens very long, but being twiſted in a ſpiral, they are retained within the corolla. It approaches to the next preceding ſpecies, but the ſtamens cannot be called ſhort, or even of a middling length.—Native of Cochinchina [i].]

PROPAGATION AND CULTURE.

1. 2. Sow the ſeeds in autumn, in pots filled with light earth: in winter place the pots under a frame, to ſhelter them from ſevere froſt, but expoſe them to the open air at all times when the weather is mild. In the ſpring tranſplant them on to a bed of light earth; ſhading them from the ſun till they have taken new root, and keep them clean from weeds.

TRICHOSTOMUM. (*Hairy-mouthed.*) One of Hedwig's genera of Moſſes, including ſome of Linneus's Bryums. One of them, namely T. capillaceum, is figured in *t.* 1152 of Engliſh Botany.

TRICOLOR. See *Amaranthus*.]

TRIDAX. (*Θριδαξ is the name of ſome pot-herb in Dioſcorides, Athenæus and Pliny.*

Lin. gen. n. 972. *Reich. n.* 1054. *Schreb. n.* 1314. *Juſſ.* 190.

[g] Hort. kew. [h] Dill. eltb. [i] Loureiro.

Claſſ.

Class. 19. 2. Syngenesia Polygamia Superflua.
Nat. order of *Compositæ Oppositifoliæ. Corymbiferæ* Juss.

GENERIC CHARACTER.

CAL. *Common* cylindrical, imbricate: *scales* ovate-oblong, obscurely acute, erect.

COR. *Compound* radiate: *Corollets* hermaphrodite, tubular in the disk: *female* in the ray.

Proper in the Hermaphrodites funnel-form, five-toothed, erect:—in the Females ligulate, three-parted; segments equal, the middle one narrower.

STAM. in the Hermaphrodites, *Filaments* five, capillary, very short. *Anther* cylindrical, tubular.

PIST. in the Hermaphrodites: *Germ* oblong. *Style* bristle-shaped, length of the stamens. *Stigma* obtuse:—in the Females, *Germ* oblong. *Style* filiform, length of the corollet. *Stigma* obtuse.

PER. none. *Calyx* unchanged.

SEEDS in the Hermaphrodites solitary, oblong: *down* many-rayed, simple, a little longer than the calyx:—in the Females, very like the others.

REC. chaffy, flat: *chaffs* lanceolate, shorter than the seed.

ESSENTIAL CHARACTER.

Cal. imbricate, cylindrical. *Corollets* of the ray three-parted. *Down* many-rayed, simple. *Recept.* chaffy.

SPECIES.

1. Tridax procumbens.
Lin. spec. 1268. *Reich.* 3. 872. *hort. cliff.* 418.
Aster americanus procumbens, foliis laciniatis & hirsutis. *Houst. mss.*

DESCRIPTION, *&c.*

Stalks trailing and emitting roots at the joints, herbaceous and hairy. Leaves placed by pairs, rough, hairy, about an inch and half long, and three quarters of an inch broad, ending in acute points, and acutely jagged on the edges. The flowers are produced upon long naked peduncles which terminate the branches. The florets are of a pale copper colour, inclining to white.

This plant was discovered by Dr. Houstoun, growing naturally by the road-side leading to old La Vera Cruz, in America.

PROPAGATION AND CULTURE.

Sow the seeds in pots plunged into a hot-bed. When the plants are fit to remove put each into a small pot, filled with light earth: plunge the pots into the tan-pit; shading them from the sun till they have taken new root, and then treating them as other tender plants from the West Indies, placing them in autumn in the bark-stove, where they should constantly remain.

As it rarely perfects seeds here, this plant may be increased, by planting pieces of the stalks, which put forth roots at the joints.

[TRIENTALIS. (*So named from its small size.*)
Lin. gen. n. 461. *Reich. n.* 496. *Schreb. n.* 626. *Gærtn. t.* 50. *Juss.* 96.
Class. 7. 1. Heptandria Monogynia.
Nat. order of *Rotaceæ. Lysimachiæ* Juss.

GENERIC CHARACTER.

CAL. *Perianth* seven-leaved: *leaflets* lanceolate, acuminate, spreading, permanent.

COR. stellate, flat, one-petalled, equal, seven-parted, very slightly cohering at the base: *segments* ovate-lanceolate.

STAM. *Filaments* seven, capillary, inserted into the claws of the corolla, patulous, length of the calyx. *Anthers* simple.

PIST. *Germ* globular. *Style* filiform, length of the stamens. *Stigma* headed.

PER. *Berry* capsular, juiceless, globular, one-celled, covered with a very thin crust, opening by various sutures.

SEEDS some, angular. *Receptacle* very large, hollowed out for the seeds.

OBS. *Seven is the most common number in this plant, though it sometimes varies.*
The fruit is a dry Berry, not opening by valves, as the capsule does.

ESSENTIAL CHARACTER.

Cal. seven-leaved. *Cor.* seven-parted, equal, flat. *Berry* juiceless.

P. brasiliana alsines flore major & minor. *Park. theat.* 509. *f.* 5.

DESCRIPTION, *&c.*

Root perennial, somewhat tuberous, creeping. Stem simple, erect, a span high, almost naked at bottom, leafy at top. Leaves clustered, spreading, lanceolate, quite entire, smooth, veined. Peduncles terminating, aggregate, one-flowered, spreading. Flowers snow-white, very elegant. Leaflets of the calyx awl-shaped. Corolla divided almost to the base, permanent. Stamens varying in number (from five to seven, most frequently six, with the same number of segments to the calyx, *Pallas*), filiform. Anthers purple. Germ superior. Stigma emarginate. Berry membranaceous. Seeds numerous (about eight *G.*) gibbous, dotted, fastened to a globular, central receptacle [k]; which is very large, honey-combed and fungous. The seeds are subovate, flatted a little, very slightly convex on one side, and angular on the other, hollow-dotted, and of a dark colour; they have a very small white navel in the middle of the belly [l].

Native of the northern parts of Europe, Canada and Siberia, in woods on the sides of mountains, and on turfy heaths. Thomas Willisell first showed it to Mr. Ray, in Yorkshire and Northumberland. It is more plentiful in Scotland.

Linneus, in his Flora Lapponica, appears to have been quite enchanted with this plant, possibly from its being the only Lapland genus of his seventh class. It must be confessed however that the number of its stamina is very inconstant [m].

It is found also in Norway, some parts of Germany, Silesia, &c. Villars sets it down as having been discovered in Dauphiné; but he had not seen it himself. It flowers here from may to july.

TRIENTALIS CAPENSIS. See *Septas.*

DESCRIPTIONS, &c.

1. This is an annual plant, with large hollow, channelled ſtalks, that riſe about a foot high, and ſend out many branches. Leaves ternate, with ovate leaflets, ſlightly ſerrate, ſtanding upon pretty long foot-ſtalks. The flowers are collected in oblong ſpikes, which ſtand upon very long foot-ſtalks, ſpringing from the axils at every joint of the ſtalk the whole length of it: they are of a pale blue colour, and ſhaped like thoſe of the common Melilot. [The legume is not much longer than the awl-ſhaped teeth of the calyx, obovate, terminated by the awl-ſhaped ſtyle, membranaceous, looſely netted with longitudinal nerves running into one another, one-celled, valveleſs. Seeds two or four, (Miller ſays two or three,) of a rounded kidney ſhape, ſmooth, yellow[a].

Native of Germany. Cultivated in England before 1562, by William Turner, M. D. It flowers in auguſt and ſeptember[b].] Mr. Miller ſays, that the flowers appear in june and july, and that the ſeeds ripen the beginning of ſeptember; that the whole plant has a very ſtrong ſcent like that of Fenugreek, and periſhes ſoon after the ſeeds are ripe.

[2. This has the appearance of common Melilot, (n. 5.) but is very tender, only two feet high, and upright. Branches from the axils ſhorter. Stipules entire, acuminate. Leaves obverſely ſubcordate oblong, toothletted, ternate. Flowers white or yellow, but ſo ſmall that their parts can ſcarcely be diſtinguiſhed by the naked eye. Fruiting ſpike long. Legumes roundiſh, wrinkled, ſurrounded by the calyx at the baſe only, nodding[c].

Loureiro deſcribes the ſtem as annual, a foot and half high, round, with diffuſed branches: the leaves ternate, ovate, quite entire: the flowers purple, terminating, in ſhort racemes: the legumes lanceolate-ovate, compreſſed, one-ſeeded, naked. According to Gærtner, they are membranaceous, very thin, cloſely netted, obtuſe, with a very ſhort calyx at the baſe: ſeeds one or two, ovate or angular kidney-ſhaped, ferruginous.

Native of the Eaſt Indies, China, Africa and Italy, if the plant be the ſame in all theſe countries.

There are ſeveral varieties, which according to Linneus ſcarcely poſſeſs ſufficient marks to diſtinguiſh them. The laſt is ſeparated by Desfontaines, who found it among corn in Algiers, under the name of Melilotus parviflora. It differs, ſays he, from M. officinalis, in having a ſhorter ſtem, and flowers three or four times ſmaller.

Moriſon deſcribes the ſtems as ſtraight, from a foot to eighteen inches high; leaves ſmaller and more rounded at the ends; flowers yellow, very ſmall, in very cloſe ſpikes; legumes very ſmall, brown.

Ray compares it with M. italica, than which, ſays he, it is ſmaller in all its parts; ſtems eighteen inches and more in height, erect, round, green, never red: leaves much ſmaller, leſs glaucous; lower ones broad and almoſt cordate, entire, upper ones long, narrow, crenate, obtuſe and as it were cut off at the end: flowers honey-coloured but ſmaller, in ſpikes from the axils of the upper leaves, more frequent than in the italica: legumes round, wrinkled. Native of Dauphiné; whence ſeeds were ſent by Berhard to Moriſon, who cultivated it at Oxford before 1672.

It was cultivated by Mr. Miller in 1739[d]: but is omitted in the later editions of his Dictionary.

3. This alſo is an annual plant as well as the two former, and has the appearance of the common ſort. Leaves ternate, fleſhy, ſubſerrate. Flowers yellow, ſmall. Legumes rather oblong, whitiſh, wrinkled with ſemicircular ſtreaks. Seeds bigger than in M. officinalis[e].

Stem erect, round. Leaves obovate, ſerrulate. Racemes axillary, ſhort, erect. Legumes ſemiovate, gibbous, with bowed parallel ſtreaks[f].

Peduncles axillary, ſhorter than the leaf. Flowers ſmall, yellow, raceme-headed. Legumes one or two-ſeeded, ſubcompreſſed, pendulous, oblong, at-

[a] Gærtner. [b] Hort. kew. [c] Linn. zeyl. [d] Hort. kew. [e] Linn. mant. [f] Linn. ſuppl.

tenuated

Digitized by Google

tenuated to both ends, acute, ſlightly curved in on one ſide [g].

Native of Sicily, Italy and Barbary. Ray gathered it on the point of land lying between the Sicilian ſtraits and the port of Meſſina [h]. Moriſon had the ſeeds of this alſo from Berhard the Apothecary, whom he calls; rei herbariæ callentiſſimus. It flowered in the Oxford garden in 1672 [i].

4. This differs from the next ſpecies, in having the ſtem altogether round; the leaves ſmaller, acuminate, acutely ſerrate at top; the flowers in the raceme remote and on longer pedicels; the peduncles round, not grooved; the banners of the flowers folded back, and with the wings not outwardly and longitudinally converging at their edges, but obliquely divaricating; the legumes two-ſeeded, little wrinkled, lanceolate-acuminate, longer. The ſtature and odour are the ſame. The flowers are of a very pale yellow colour [k].

Gærtner deſcribes the legume as coriaceous, of a lanceolate-ſickle ſhape, turgid, beautifully netted with bowed anaſtomoſing ſtreaks, one-celled, two-valved, but ſcarcely opening ſpontaneouſly. Seeds two, inſerted into the concave ſuture, three-cornered-globular, ſmooth, ruſeſcent.

Native of Poland. Introduced in 1778, by Mr. Thouin. It flowers here from june to auguſt [l].

5. Root annual, ſtrong, woody. Stem upright, grooved, yellowiſh-green, two feet high or more, with ſpreading alternate branches. Leaves ternate, petioled, alternate: leaflets ſmooth, lanceolate-obovate, or according to Mr. Woodward, the lower ones oblong wedge-ſhaped, the upper elliptical; they vary indeed much in form, and are commonly ſerrate, but ſometimes nearly entire. Flowers ſmall, drooping, varying in colour, but with us almoſt always of a golden yellow colour: they grow in long, peduncled, axillary ſpikes, very cloſe together, on ſhort capillary pedicels, each having a ſmall awl-ſhaped bracte. Calyx bell-ſhaped, hairy, one-third of the length of the corolla, divided half way down, into five nearly equal acute teeth. Legume pendulous, elliptic, very ſhort, turgid, ſharp at both ends, wrinkled tranſverſely, hairy; containing one or two, yellowiſh, roundiſh, ſmooth ſeeds [m].

Common Melilot grows wild in moſt parts of Europe, in corn-fields, paſtures, and by way ſides. Mr. Miller marks Cambridgeſhire, and Gerarde Eſſex, for abundance of it. There cannot be a worſe weed among bread-corn, for a few of the ſeeds ground with it ſpoil the flour, by communicating their peculiarly ſtrong taſte. It flowers in june and july, and the ſeeds ripen with the corn.

The whole plant has a peculiar ſcent, which becomes more fragrant in a dry ſtate, then having ſome reſemblance to that of Anthoxanthum. The flowers are ſweet; a water diſtilled from them poſſeſſes little odour in itſelf, but improves the flavour of other ſubſtances. In medicine it was eſteemed emollient and digeſtive, and was uſed in fomentations and cataplaſms, particularly in bliſter-plaſters; but it is now laid aſide, as being rather acrid and irritating than emollient.

Notwithſtanding its ſtrong ſmell and bitter acrid taſte, it does not appear to be diſagreeable to any cattle; and horſes are ſaid to be extremely fond of it. Hence it is called by ſome Italian writers Trifolium caballinum.

Mr. Ray affirms that it is ſometimes ſown in England for the food of kine and horſes. We do not know that it is now ever cultivated among us. Bees are very fond of the flowers [n].

The firſt variety differs only in having white flowers; but the laſt has a biennial root, a higher ſuffruteſcent ſtem, and ſmaller flowers, with the banner bent down at the ſides [o].

6. Leaflets obovate, ſmooth, rounded at the end, toothletted. Peduncles ſtriated. Flowers ſmall, yellow, in racemes. Legumes nodding, round, thickiſh, ſcored with little pits [p]: according to Gærtner, coriaceous, ſubglobular, very ſhortly mucronate, tortuouſly wrinkled on the ſides, but having a ſmooth prominent ſuture at the edges, not opening. Seed one or two, kidney-ſhaped, ruſeſcent.

Native of Italy. Cultivated in 1596, by Gerarde. It flowers from june to auguſt [q].

Desfontaines has another ſpecies, which he names Melilotus ſulcata, and ſays it is allied to this and the third; but differs in having a procumbent ſtem, and legumes ſtriated in a bow not porous as in M. italica, nor acute as in M. meſſanenſis. It is a native of Algiers, in corn-fields.

7. This has the habit of Melilotus italica, with thick leaves, ſcarcely ſerrate, fleſhy, inodorous, obtuſe [r]. Flowers in racemes, nodding. Legumes membranaceous, flat, ovate-orbicular, pendulous, containing one or two ſeeds [s]: netted with tranſverſe parallel capillary veſſels, pale ſtraw-coloured, ſubmarginate, not opening. Seed kidney-ſhaped, covered with very minute raiſed dots, flatted a little, ferruginous. When there are two ſeeds, they are placed tranſverſely [t].

Native of Candia and Algiers.—Cultivated here in 1713, and flowering from june to auguſt [u].

8. The fibrous root is furniſhed with ſmall fleſhy knobs, as in Vicia lathyroides and ſome others of this claſs, apparently to reſiſt accidental drought during ſummer. Stems from two to five inches long, forming a circle round the root, and lying cloſe to the ground, ſmooth and moſtly unbranched. Leaves on long ſlender foot-ſtalks, with each a pair of lanceolate, pointed, united ſtipules, large in proportion to the plant. Leaflets ſeſſile, moſtly obcordate, ſmooth, ribbed, more or leſs acutely and diſtantly ſerrate. Peduncles axillary, much ſhorter than the leaf-ſtalks, bearing uſually two, but ſometimes one, three or even four ſlender pale-red flowers, growing parallel to each other. Calyx more than half as long as the corolla, pale veined with deeper green, divided half way down into five nearly equal ſetaceous ſegments. Petals with long claws. Pods oblong, tranſverſely rugged, almoſt twice as long as the calyx, thick, blunt but terminating in a ſhort point turned downwards, which gives them ſomething the appearance of a bird's claw, whence the trivial name. They contain about eight ſeeds [x].

Linneus remarks that this plant is an intermediate ſpecies between the Trifoliums and the Trigonellas.

Native of Denmark, France and Britain, on dry gravelly heaths and paſtures, among ſhort graſs, flowering in june and july. Thomas Williſel found it among corn, half a mile from Tadcaſter toward Sherborn; alſo near Oxford in the like grounds. Mr. Newton in company with Mr. Ray found it on the ſandy banks by the ſea-ſide at Toleſbury in Eſſex: and Mr. Doody in Tuthill-fields, Weſtminſter [y]. Mr. Curtis found it there, and on Blackheath. Mr. Pitchford on Mouſhold-heath, near Norwich. Mr. Hudſon about Marazion and Penzance in Cornwall. At Maitland-bridge between Muſſelburgh and Edinburgh. But probably the ſmall ſize and proſtrate poſition of this Trefoil, may have cauſed it to be thought more rare than it really is. It is annual, as are all the preceding ſpecies.

9. Root perennial. Stems ſeveral, from a foot to eighteen inches in height, round, with ſeveral (ſeven or eight) joints, green or purpliſh; at each joint is a ſheath terminating in a digitate leaf, the number of leaflets varying from three to ſix or ſeven, but the extreme numbers are rare, and five is the moſt common: the leaves have more reſemblance to thoſe of a Lupin than of a Trefoil, and hence the names of *Lupinaſter* and Baſtard Lupin. The leaflets are lanceolate, finely ſerrate, and unequal in ſize. There are uſually ſeveral heads at the end of the ſtem, of a roundiſh form, with the flowers pretty thickly ſet: the three lower teeth of the calyx are nearly the length of the keel, the two upper ones are ſhorter: the banner of the corolla is oblong, near half an inch in

[g] Desfontaines. [h] Ray hiſt. [i] Mor. hiſt. [k] Linn. ſpec. [l] Hort. kew. [m] Woodw. Mſs. Fl. ruſt. Smith brit. [n] Fl. ruſt. Withering. [o] Linn. ſpec.

Digitized by Google

length, and purple; the wings are broadiſh, and pale purple; the keel is pale, and of the ſame length with the wings. The pod is longer than the calyx, pale brown, and contains four or five ſeeds. The circumſtance of having more than three leaflets, uſually five, is ſufficient to diſtinguiſh this ſpecies [z].

Native of Siberia. Cultivated in 1763 by Mr. James Gordon. It flowers in july and auguſt [a]. Thunberg found it in Japan, but in a ſtate of cultivation.

Desfontaines has a ſpecies, which he names *levigatum*, and figures in *t.* 208. It is the ſame which Poiret has given, *vol.* 2. *p.* 219. This has the habit of *T. lupinaſter*, but differs in having concave ſtipules toothed at the end and ſolitary, the head of flowers peduncled, and the corollas, which are pale yellow, ſhorter than the calyx. The leaflets, which are three only, are lanceolate and ſerrate. He found it in meadows near La Calle in Barbary.

10. Leaves ſoft. Seeds two or three [b].—Native of Virginia.

11. Root annual. Stem branched at bottom, patulous, even. Leaves on long petioles; leaflets ſmooth, ſtriated, the lower obovate, the upper elliptic, finally lanceolate. Stipules very wide, rhombed with an awl-ſhaped point. Peduncles grooved, axillary, ſhorter than the petiole. Spikes with an oblong or ſubglobular rachis. Calyx naked, with awl-ſhaped teeth; the two upper ones longer than the corolla, after flowering bent back with the teeth ſpreading. Corolla very ſmall. Between the flowers linear acuminate bractes, ſcarcely the length of the corolla [c].—Native of Italy and Spain, in paſtures.

12. Root perennial. Stem branched, grooved, a foot high, aſcending, not creeping. Stipules lanceolate acute, ending in a hair. Leaflets ovate-acute, ſerrate-toothletted. Peduncles not very long, but yet jointed, as in the ſpecies next following. Receptacle ovate, concave. Chaffs lanceolate, linear, very acute. Corollas gaping [d].

Desfontaines deſcribes a plant under this name, but he doubts whether it be the *hybridum* of Linneus, the pod having only two ſeeds or thereabouts. The corolla is of a pale roſe-colour; whereas in the true *hybridum* it is white turning brown, as in repens. Retzius however ſays it is always tinged with red. This author ſuſpects that Vaillant's plant is a different ſpecies; that being annual, and much taller, with white flowers.

Native of ſeveral parts of Europe. Linneus thinks it was at firſt produced, by the pollen of Tr. pratenſe impregnating the germ of Tr. repens.

The *hybridum* of Hudſon is only a more branching and upright variety of the *repens*, and quite diſtinct from the *hybridum* of Linneus [e].

13. Root perennial, fibrous. Stems numerous, proſtrate, creeping, extending wide, branched at the baſe, leafy, ſmooth. Leaves on long petioles. Leaflets nearly ſeſſile, ovate or obcordate, toothletted, ſmooth, moſt commonly having a brown and white arch or creſcent in the middle. Stipules lanceolate-ovate, in pairs, lengthened out into an awn, veined with purple. Petioles and peduncles very long, aſcending or upright. Flowers many, as far as ſixty, in a cloſe head, very large in the cultivated plant, and of a round ſhape: each flower is on a ſhort pedicel, and has a ſmall awl-ſhaped bracte. Calyx ſmooth, and generally reddiſh, marked with ten ſtreaks; the teeth nearly equal, only the two upper ones rather longer than the others. Corolla white or tinged with purple, permanent. The flowers ſtand upright till they are withering, and then they hang down. Legumes oblong, round, ſmooth, covered with the corolla, containing from two to four (commonly three or four) ſeeds.

White Clover is common in paſtures through the greater part of Europe; flowering from the end of may to ſeptember. There are many varieties, depending on richneſs or poverty of ſoil. Haller has noticed no leſs than eleven. Mr. Curtis has obſerved two more remarkable: one with leaves of a deep purple colour, cultivated in gardens as an ornamental plant; the other proliferous, or having ſmall heads of leaves growing out of the flowers. In a fertile moiſt ſoil, as Dr. Smith remarks, it has a more upright branching ſtem, but it is ſtill ſufficiently diſtinct from T. hybridum.

On all our good lands it ſeems to come ſpontaneouſly; but however this may be, the growth of it is much encouraged by ſpreading of aſhes or other manure. It does not come early, neither is it of a tall growth; but it forms an excellent bottom in paſtures, and produces great abundance of ſucculent ſtalks and leaves, affording late feed in dry ſummers, when graſſes are moſtly burnt up. Mr. Curtis affirms that a ſingle ſeedling, in his garden, covered more than a yard ſquare of ground, in one ſummer.

It does not ſeem to be aſcertained when this White Trefoil came firſt into cultivation here, but it ſeems to be of late date: for it is not mentioned by Gerarde, Parkinſon, or Ray, as an agricultural plant in this country, nor by any of the writers on huſbandry of the 17th century, as far as we have been able to diſcover.

Gerarde however ſays, that there is a Trefoil of this kind, which is ſown in fields of the Low Countries in Italy, &c. that cometh up ranker and higher than that which groweth in meadows, and is an excellent food for cattle, both to fatten them, and cauſe them to give great ſtore of milk. *Herball, p.* 1018. *edit.* 1597 [f].

14. Native of America.

15. Root very large. Leaflets hard, bright green, entire, ſmooth. Flowers on a ſcape or naked ſtem two or three inches in length, purple or bright red. Segments of the calyx very long, the upper ones wider, the loweſt capillary. Banner very long, ſtriated, fleſh-coloured with purple lines, keel very ſhort, wings longer. Legume ſhort, turgid, containing two ſeeds. Native of the Alps, Pyrenees, Monte Baldo, &c. [g] Introduced in 1775, by Drs. Pitcairn and Fothergill. It flowers from june to auguſt [h].

It is called *Regliſſe des Alpes*, from the taſte of the root, and becauſe it is uſed inſtead of Liquorice in the Alps [i].

16. Root annual, fibrous, furniſhed with knobs. Stems proſtrate, about three inches in length, or longer, ſpreading cloſe to the ground, almoſt concealed by the broad ſheathing ſtipules of the numerous leaves. Leaflets obcordate, hairy on both ſides, entire. Peduncles bearing three or four flowers, at firſt erect, but before the fruit ripens they are bent to the ground, producing from their extremities, little white thick fibres, ſtar-like at their tips, which become recurved and rigid, enveloping the fruit: theſe look ſo like roots, that till Mr. Curtis explained their economy, they were miſtaken for ſuch, and Dillenius, aware that the plant being an annual, did not propagate itſelf by theſe ſuppoſed roots, conjectured they might draw moiſture to nouriſh the ſeed. The long ſlender milk-white petals render this ſpecies conſpicuous, though when firſt ſeen, they are ſeldom taken for the flowers of a Trefoil. The calyx-teeth are long and hairy. Pod thin, covered by its calyx, containing one dark-brown ſeed [k].

Native of France, Italy, Spain, and England, in expoſed gravelly ſituations, and particularly in heaths, as Blackheath, Hyde Park, Greenwich Park, &c. where its flowers are viſible among the ſhort graſs in may, and through the ſummer to auguſt. Gamlingay by the windmills, and near White-wood, Cambridgeſhire. Between Eltham and Deptford, Kent. Bath-hills, near Bungay, Suffolk. Mangotsfield-common near Bath. Salt-marſh at Lymington. Shotover-hill, by the road to Cuddeſdon, Oxfordſhire. Ampthill and Clophill, Bedfordſhire.

17. Root annual. Stems filiform, a foot long, decumbent. Heads lateral, globular, villoſe, peduncled.

Digitized by Google

The lower florets only corolled and fertile; the reſt mutilated and drying away into a woolly ſubſtance, fill the head, bend back to the ſides and conceal the fertile calyxes[l].

Loureiro deſcribes the ſtem as annual, a foot and half long, nearly upright, branched; the leaflets oblong; the flowers pale, axillary and terminating, in a globular head, ſurrounded with many white villoſe hairs, the upper ones without petals and barren. Legumes ovate, one-ſeeded.

Native of Arabia, Syria and China.

Loureiro has another ſpecies, which he names Trifolium cuſpidatum. It has a perennial, ſuffruticoſe ſtem, four feet high, hirſute, erect, with aſcending branches: leaflets linear, quite entire, with a ſharp cuſp having a rounded tip growing to them; flowers lateral on ſubcapitate peduncles, few together; calyxes hairy; banner of the corolla ovate, white with a purple ſpot: legume naked, one-ſeeded.

Native of Cochinchina.

He has alſo a third ſpecies, which he names Tr. volubile, which has an herbaceous, ſlender, round, long, procumbent ſtem, frequently becoming twining: the leaflets roundiſh, quite entire, tomentoſe: flowers yellow, in axillary many-flowered heads: legumes oblong, acute, naked, ſmooth, two-ſeeded. Native of the eaſtern coaſt of Africa.

18. This is allied to the next, but the whole calyxes are hairy. Stemlets tomentoſe. Bractes three, very large, cordate, coloured at the edges. Stipules the ſize of the leaves[m]. Annual.

Stems many, villoſe, procumbent. Leaves the ſize of T. agrarium, villoſe, obcordate. Stipules membranaceous, ovate, acuminate, ſheathing. Flowers in terminating, ſeſſile, ſolitary heads. Involucres three to five-leaved, large, concave, orbicular, coloured at the edge, embracing the hemiſpherical head, one three-leaved. Flowers denſe, heaped. Calyx-teeth ſetaceous, equal, very villoſe. Corolla ſmall, ſhorter than the calyx[n].

Native of France, Italy, and the hills about Algiers. —Introduced in 1768, by Monſ. Richard. It flowers in may and june[o].

19. Plant annual. Stems diffuſed. Lower leaves petioled, upper ſubſeſſile: leaflets obtuſe, indiſtinctly ſerrulate. Stipules linear-ſubulate. Heads terminating, ovate-rounded. Calyxes after flowering elongated. The calyx-teeth have a few ſtiff hairs at the end, which render the head hiſpid[p].

Leaves cordate, nerved, ciliate at the edge. Spikes terminating, ovate, hiſpid[q].

Native of France, Spain and Italy.

20. This is a large elegant Trefoil. Stalks one or more, ſimple, upright, ſtrong, round except that they are a little flatted towards the top, coloured, from a foot to near two feet in length. Leaves oblong, elliptic, or lanceolate, three or four inches in length, not unlike thoſe of Trifolium alpeſtre, naked or void of hairs on both ſides, finely ſerrate round the edge by means of the veins running out into ſmall curved points directed towards the top, ſhorter and longer alternately. The ſtipules with their ſheaths are very large, in a manner covering the ſtalk, and are not hairy: the former are ſometimes obſcurely ſerrulate, and the latter, eſpecially the upper ones, are much inflated. There is uſually only one ſpike of flowers to a ſtalk, but in gardens there are ſometimes two. The ſpike is at firſt ſeſſile, and concealed within the floral ſheaths, with a leaf on each ſide of it; but as it advances becomes peduncled: it is of an oblong oval or cylindric form, blunt at the top, two or three inches in length, upright, and the flowers are very cloſe ſet; with leaflets or bractes between them. Calyx in reality ſmooth, but the teeth having long white hairs on them, which ſpread very much, the whole has the appearance of being hairy: the four upper teeth are very ſhort, but the fifth tooth is as long as the whole corolla, and at leaſt three times as long as the other teeth. Corolla one-petalled, of a dark red purple: tube long; banner ovate and ſharp; wings bluntiſh, ſpreading or rolled back, of the ſame length with the banner, but of a paler colour; keel ſhorter, and of a darker purple[r]. Legume roundiſh, flat, one-ſeeded[s].

Native of the South of Europe, and about Algiers in Africa. As far as we know, it has not been cultivated for cattle: it ſeems to be of a good quality, and to be ſufficiently productive. Linneus marks this Trefoil as annual, but there is no doubt of its being perennial.

Jacquin's figure is drawn from a tall plant, and thus bears ſome reſemblance to *Tr. alpeſtre.* The ſpike varies much in length, from one inch to four inches: hence Caſpar Bauhin's two ſpecies—*ſpica oblonga rubra* and *longiſſima rubente*[t].

This is a larger plant than the *alpeſtre*, the leaves are free from hairs on both ſides, and the edges are finely ſerrated, as in *Tr. montanum*; both ſheaths and ſtipules are much larger, and not hairy, the former ſwelling, the latter ſerrulate; ſpikes at firſt ſeſſile, but afterwards peduncled; calyx ſmooth, the teeth only hairy or ciliate, and the loweſt tooth as long as the whole flower[u].

I have ſeen this, ſays Johnſon, (1633) in the gardens of ſome of our floriſts. It flowers in may and june[x].

21. Root perennial, ſtriking almoſt right down, and ſcarcely creeping, branching, granulated, aſh-coloured. Stems aſcending, a foot high and more, below flatted a little on one ſide (when dried three-cornered) otherwiſe round, above ſtriated and ſomewhat villoſe, uſually ſomewhat branched, branches ſpreading, without any axillary tumour; green or tinged with browniſh red. Stipules wide-ovate, connate, pale, ending in a ſhort capillary awn hairy eſpecially towards the tip, having purple nerves branching towards the edge and anaſtomoſing, ſheaths very wide, embracing, bowed on each ſide at the edge, ſmooth or ſometimes a little hairy. Petioles unequal, moſtly very long, many times longer than the ſtipules, ſpreading. Leaflets unequal, ovate or oval, obtuſe, thoſe of the lower leaves much ſmaller, almoſt orbicular, retuſe, all with depreſſed veins on the upper ſurface, and with raiſed ones on the lower, for the moſt part marked on the upper ſurface with a central pale ſubſagittate ſpot; they are ſubciliate, and moſtly quite entire, but ſometimes ſlightly and acutely crenulate. Spikes of flowers terminating, ovate, obtuſe, ſolitary, (very ſeldom two,) ſometimes peduncled, but commonly ſeſſile between two oppoſite erect floral leaves. Flowers many in a ſpike, cloſely imbricate, erect, having a peculiar ſmell. Calyx ſilky, hairy, pale, ſometimes tinged with purple, with ten ſtreaks dark green or red, ſeldom brown: teeth awl-ſhaped, green, often more or leſs tinged with red; the four upper ones equal, the length of the tube of the calyx, the loweſt a little longer, (twice as long *Sm.*) yet ſhorter than the tube of the corolla, erect when the ſeed is ripe, whereas the others ſpread very much. Corolla purple, one-petalled: banner longer than the wings, truncate and often emarginate, with ſtreaks of deeper purple; wings paler, longer than the keel. Legume one-ſeeded[y].

On comparing carefully the purple Clover as cultivated, with our perennial Trefoil as it grows in our dry paſtures, I found that the ſtalks were much ſmaller, ſtiffer, and more pubeſcent in the latter, and that they were not grooved; the leaf-ſtalks were very long and pubeſcent; the leaflets ſmaller and much more pubeſcent, even the upper ſurface as much ſo as the lower ſurface of the other, with white hairs cloſely preſſed to the ſurface; the ſheaths narrower, not pubeſcent, but ending in much longer points, which are ſet with long white hairs ſtanding out; ſpikes or heads of flowers more lengthened out than in the cultivated plant, having fewer flowers, and varying in colour from the paleſt to full purple; on each ſide of the ſpike was a leaf as in the other, but ſmaller, extremely pubeſcent, and not always ſeſſile,

[l] Linn. ſpec. [m] Gouan, Linn. mant. [n] Desfontaines. [o] Hort. kew. [p] Ger. prov. [q] Aſſo. [r] Fl. ruſt. [s] Aſſo. [t] Fl. ruſt. [u] Afzelius. [x] Ger. emac. [y] Afzelius and Smith brit.

the

the involucral ſheath from which theſe floral leaves riſe was very hairy about the edge; the ſpike was more villoſe, and when young extremely ſo; tube of the calyx greeniſh white with purple lines, ending in five long purpliſh ſegments, having many white hairs ſtanding out, and diſpoſed as in the cultivated Clover, but the firſt and ſecond pair more different in their lengths; tube of the corolla white or pale purple; wings much longer than the keel, but much ſhorter than the banner, which is marked with lines of a deeper purple; the keel purple, but the wings uſually white, at leaſt in the middle within [a].

This was erroneouſly ſet down in Flora ruſtica, for the Trifolium medium of Hudſon's firſt edition, and alpeſtre of the ſecond edition, of the Flora anglica; but I can vouch for the accuracy both of the deſcription and figure given in Flora ruſtica. Moſt of the differences between this wild and the cultivated Clover, may be accounted for from ſoil and culture; and the varieties even of the wild Trifolium pratenſe are numerous. It is common in paſtures all over Europe, and is found in Siberia, Barbary and North America; ſo that it is indigenous of the four continents. It flouriſhes moſt in fertile moiſtiſh ſoils, and open ſituations, but does not reject drier, and even barren ſoil, and ſhady places: flowering from may to ſeptember.

Trifolium pratenſe is very diſtinct from the next ſpecies, with which it has been confounded. The root is much ſmaller; the ſtems are not flexuoſe, in the wild plant they are lower, more procumbent, often ſolitary, leſs branched, and not unfrequently quite ſimple; the ſtipules are ſmall and differently ſhaped; the ſheaths much larger, not ciliate, and commonly veined with red or brown; there are always two floral leaves; the leaflets are ſhorter, for the moſt part ovate, blunter, commonly ſpotted with white, and more indiſtinctly veined, the veins on the upper ſurface in the living plant depreſſed, but in the dried one raiſed; the ſpike is ſmaller, much leſs frequently peduncled or double, and not flatted at the top; the calyx never quite ſmooth; the corolla ſmaller, much more unequal, for the moſt part of a paler purple, or at leaſt with the wings not deeper coloured at the end, as in Trifolium medium; the banner alſo is narrower, and it flowers earlier.

β The cultivated purple Trefoil, commonly known by the name of Broad Clover, is much larger and ſmoother than the wild plant, and has more ſtems, the leaflets are ſharper, the ſpike is moſtly peduncled, and not ſo unfrequently double, the calyx is for the moſt part more villoſe, with the lower tooth longer in proportion, the banner and wings of the corolla are more diverging, the ſtyle is frequently ſhorter, and the legume two-ſeeded. In this ſtate, the ſtems being diffuſed and having a tendency to bend, it looks ſo like *Trifolium medium* at a diſtance, that it might eaſily be taken for it, but on a nearer inſpection it may be eaſily diſtinguiſhed by the ſtipules, and particularly by the calyx-teeth, which are very different [a].

Mr. Woodward and Dr. Stokes are of opinion that this differs from the wild plant in nothing but ſize. Mr. Swayne on the contrary thinks it ſpecifically different, the heads of that being globular, of this oval. It ſeldom remains in the ground more than two years [b].]

Mr. Miller alſo aſſerts, that he has often ſown the ſeeds of the cultivated red Clover, and the wild red meadow Trefoil in the ſame bed, and that they conſtantly produced the two ſpecies without varying. He obſerves, that the ſtalks of the Meadow Trefoil are weak and hairy, the ſtipules, which embrace the foot-ſtalks of the leaves are narrow and very hairy; the heads of flowers are rounder and not ſo hairy as thoſe of the red Clover, the ſtalks of which are ſtrong, almoſt ſmooth, furrowed, and riſe twice the height of the other; the heads of flowers are large, oval and hairy, the corolla opens much wider, and the tube is ſhorter than that of the wild ſort. Clover

[a] Fl. ruſt. 2.

[a] Afzelius in Linn. tranſ. 1. 245.
[b] Withering.

has been ſo much cultivated in England for near a hundred years paſt [c], that the ſeeds have been ſcattered over moſt of our paſtures, and this has deceived the botaniſts into an opinion that the Meadow Trefoil is improved into Red Clover by culture.

[In a cultivated plant, raiſed from Dutch ſeed, I found the ſtalk browniſh red in places, grooved, white near the head of flowers with hairs preſſed cloſe to it: leaflets ovate, blotched with white on the upper ſurface, covered with hairs preſſed cloſe to it on the under ſurface, the edge not ſerrate, but ſet with hairs: the ſheaths very broad, membranaceous with ſtrong ribs: the heads of flowers globular, with a ſeſſile leaf on each ſide, riſing from a very broad ſheath, forming involucres to the head, which, when young, appears villoſe: the calyx whitiſh, ending in five long green ſegments, having a few long white hairs on them ſtanding out, the ſecond pair is very little longer than the upper pair, but the loweſt ſingle one is much longer: the tube of the corolla is white; the wings are very little longer than the keel; and the banner is longer than the wings.

Red or Broad Clover has been long under culture in Flanders and other countries on the continent of Europe, and it has at length nearly ſurmounted inveterate prejudice in Britain. Though it was ſtrongly recommended and ſhewn experimentally to be excellent in the ſixteenth century, yet at the cloſe of the ſeventeenth it was aſked, what could be the reaſon why the great advantage got in Staffordſhire and Worceſterſhire by ſowing of Clover, can ſcarce prevail with any in Cheſhire and Lancaſhire to ſow an handful upon the ſame ſort of land [d].

Sir Richard Weſton in 1645 gives an account of its culture in Flanders, and ſays that he ſaw it cutting near Antwerp on the firſt of june 1644, being then two feet long and very thick; that he ſaw it cut again on the 29th of the ſame month, being twenty inches long; and a third time in auguſt, being eighteen inches long; and all this upon heath ground. At the end of the pamphlet, which was publiſhed by Hartlib, is an advertiſement, that if any deſire to have the great Clover of Flanders, they may enquire at Mr. James Long's ſhop at the Barge on Billingſgate. Whence we may conclude, that it was then cultivated in England, at leaſt by ſome curious perſons.

Walter Blith, in 1653, is very copious in his directions for planting Trefoyle or great Claver Graſs, as he calls it; we may preſume therefore that the culture of it had made ſome progreſs at that time.

Theſe are the firſt notices that I find of the culture of Red Clover in this country.

Gerarde, in 1597, ſays there is a Trefoil, which is ſown in fields of the Low Countries, in Italy, and divers other places beyond the ſeas, that cometh up ranker and higher than that which groweth in meadows, and is an excellent food for cattle, both to fatten them, and cauſe them to give great ſtore of milk. But he gives no hint of its being then introduced into England. Nor does his editor, Johnſon in 1633, or Parkinſon in 1640. Worlidge, in 1681, has very little but what he copies from Sir Richard Weſton, Hartlib and Blith. Ray, in 1686, diſtinguiſhes accurately the greater purple Meadow Trefoil from the common; and ſays that it is ſown in fields, "pro boum & jumentorum pabulo," under the name of Common Clover-graſs. Laſtly, at the beginning of the eighteenth century, Mr. Liſle ſpeaks of it as then commonly cultivated in Hampſhire, Wiltſhire, Glouceſterſhire, Leiceſterſhire, &c.

Beſides the principal uſe to which Clover is applied, for feeding cattle, it may be mentioned that the heads are uſed in Sweden to dye woollen green. With alum they give a light, and with copperas a dark green [e]. The ſeeds alſo yield a dye.

γ. Common Purple Trefoil varies ſometimes with a white flower. And Mr. Swayne found a ſingle plant with yellowiſh-white or cream-coloured flowers,

[c] This was ſaid in 1759.

like that of the *ochroleucum*, but reſembling the *pratenſe* in every thing elſe [f].

β. This is commonly ſuppoſed, by Engliſh botaniſts, to be a variety of the *pratenſe*, on account of its having a ſimilar, though ſtarved appearance; the ſtipules being in like manner awned, and the teeth of the calyx nearly equal. But it differs in other reſpects very materially; having the leaves oppoſite, the leaflets ſmall, ſhort and obcordate, the peduncle very long, and deſtitute of floral leaves. Haller places it as a variety of his n. 378, which is the *ochroleucum* [g]. It was obſerved by Mr. Rand between Peckham and Camberwell.

Other varieties have been frequently obtruded upon the public, under the names of Cow-graſs and Marl-graſs.

Mr. Liſle, in his Obſervations on Huſbandry (p. 250.) ſays: "the broad-clover graſs, which of late "years (1707) had obtained ſome credit as a longer-"living graſs than the common broad-clover, and is "ſown under the name of Cow-graſs, I find to be "the common purple Trefoil, or honeyſuckle Tre-"foil, as deſcribed by Mr. Ray (hiſt. 944.) diſtin-"guiſhed from the great purple meadow Trefoil, "which has always hitherto been ſowed by the far-"mers, and I doubt not but always will; for by ex-"perience I find the other not to yield half the bur-"den, nor indeed in poor ground to be a longer liver "than the common ſort."

The Cow-graſs however has again been much ſpoken of. The late Mr. Curtis had ſome plants ſent him out of Hampſhire, Mr. Liſle's country, and from one of theſe it was exactly figured in the Flora Ruſtica, *t.* 36. They appeared to be large, ſucculent, coarſe and very hairy; on comparing them with ſpecimens of the wild broad Clover, which Mr. Curtis had collected from different parts of Batterſea-field, the chief diſtinctions ſeemed to be, that in the latter the heads of flowers were ſmaller, the ſtalks green and without hairs till they approached the heads, and that the flowers opened earlier. Thoſe who cultivate the Cow-graſs will judge from the figure given in Flora Ruſtica, whether theirs be the ſame plant, or whether different varieties may not be cultivated under the ſame name [h].

Marle-graſs has by ſome been ſuppoſed to be a variety of *Tr. medium*, but Mr. Swayne aſſures us that it is the native *Tr. pratenſe* [i]. It has the name from being the production of marl land, which would induce one to think that it is rather a variety of the next ſpecies than of this. It was firſt noticed and collected fifty or ſixty years ago by Mr. James, who lived on a farm belonging to the Marquis of Bath, in the pariſh of Chilcompton. By his aſſiduity in preſerving and propagating the ſeed, in the courſe of a few years it became common, and has been conſidered as a valuable ſubſtitute for red or broad Clover, to which it bears rather a ſtriking analogy, with this difference, that it will continue much longer in the land [k]. Dr. Stokes relates, on the information of a farmer, that cattle are not fond of it, till it is touched by the froſt: but that is on ſuppoſition that the Marle-graſs is *Tr. medium* [l].

22. Root perennial, deſcending, creeping, browniſh aſh-coloured. Stems ſomewhat inclining to be ſhrubby, at bottom oblique and ſubtrigonal (exactly three-cornered when dry), above nearly upright, round, flexuoſe from joint to joint, branched, branches ſpringing from a calloſe axillary tumour, deep green tinged here and there with red. Stipules long awl-ſhaped, from three to five-nerved, ſmooth, ciliate, diverging from the ſtem but converging one to another, ſheathing; ſheaths narrowed, ſomewhat embracing, ſtraight at the edge on each ſide, at firſt villoſe, but afterwards ſmooth and ciliate. Petioles unequal, the lower much longer than the ſtipules, the upper commonly ſhorter, all ſomewhat diverging. Leaflets unequal, at the beginning and below ovate, next and in the middle oblong, finally and above almoſt lanceolate and often ſomewhat attenuated, in the lower leaves much ſmaller very obtuſe and ſometimes retuſe, in the reſt larger and more acute, all more obſcurely veined on the upper ſurface, more evidently on the lower, frequently marked above with two pale longitudinal creſcents contiguous at the tips, towards the edges ſomewhat ſtriated with concurrent veins, furniſhed at the edge with many longiſh oppreſſed villoſe hairs; they are ſcarcely rugged to the touch, to the naked eye they appear quite entire, but are very finely toothletted when examined by a magnifier, eſpecially the upper leaves. The ſpike at firſt is ſpheroidal, but afterwards globular or oval; ſometimes there are two ſpikes, and then one flowers later than the other: one or both are ſeſſile or peduncled; in the latter caſe the peduncles are unequal, and there are either one or two floral leaves, which for the moſt part hang down. The flowers are diverging and looſely imbricate. Calyx compreſſed a little, ſmooth or very ſeldom hairy, pale and often here and there tinged with purple, eſpecially at the top of the ſpike; with dark green and ſometimes purple ſtreaks; teeth green and moſtly red in ſome parts, the two upper ones equal and ſhorter than the tube of the calyx, the two lower ones alſo equal but longer than the upper ones, and equal to or a little longer than the tube of the calyx, the loweſt as long as the tube of the corolla, and much longer than the next teeth, but not twice as long. Corolla odorous: banner ſcarcely longer than the wings, with a ſhort point, and ſtreaks of a deeper purple, wings paler a little longer than the keel.

This differs from *Tr. alpeſtre* in being larger in moſt of its parts, and of a darker colour, the root more woody, and more firmly fixed in the ground, the ſtems diffuſed and ſcarcely ever ſolitary, the ſtipules wider, as are alſo the ſheaths, which have more frequent veins and more commonly purple, the petioles ſomewhat hairy and not villoſe, commonly one floral leaf only, the leaflets much wider and moſt of them oblong, glaucous underneath and furniſhed with a ſmaller nerve, more indiſtinctly ſtriated towards the edges, the ſpike till it wholly flowered, flatted at top, and ſmaller than that of the cultivated plant, the ſtreaks of the calyx more raiſed and remote, the teeth leſs hairy and the loweſt tooth ſhorter in proportion, the corolla of a paler purple, eſpecially in the wings, in ſize and ſhape very like thoſe in Tr. rubens [m].

It differs from *T. pratenſe* or common Clover in its lax heads of flowers, longer and narrower ſtipules, and more unequal calyx: from both by its remarkably flexuoſe or zigzag ſtem [n].

The figure in Flora Ruſtica, though it differs from that in Engliſh Botany, is a repreſentation no leſs exact than elegant of a ſpecimen gathered in a dry elevated paſture in a clayey ſoil among buſhes; it is found alſo in chalk and in gravel with a clay bottom; in many parts of Europe, in Great Britain, Sweden, Denmark, Auſtria, Carniolia, Piedmont, Holland, Switzerland, and many parts of Germany. It flowers here in july, later than the common Clover.

In a good looſe ſoil it is ſaid to grow more ſlender, and the ſpikes to become ſmaller: but it might perhaps be worth cultivating on ſtubborn hungry clay, like its natural ſoil.

23. Root perennial deſcending obliquely, creeping, brown. Stems ſtiff and ſtraight, quite ſimple, round, pale green. Stipules long, briſtle-ſhaped, one-nerved, villoſe, approaching to the ſtem but diverging one from the other, ſheathing; ſheaths narrowed, half embracing, ſtraight at the edge on both ſides, at firſt villoſe and ciliate, afterwards ſmooth and ſcarcely ciliate except in the ſinuſes between the ſtipules and the petiole. Petioles almoſt equal, very ſhort, the length of the ſtipules, erect. Leaflets almoſt equal, and of the ſame form, which is linear-lanceolate, ſharpiſh and terminated by a little bundle of hairs, more apparently veined on the upper, more obſcurely on the

Digitized by Google

lower ſurface, ſtriated as it were towards the edges with more frequent and larger concurrent veins, rugged to the touch at the margin, where they are ſo finely toothed that the teeth are hardly viſible without a glaſs, a few ſhort hairs are ſcattered round. Spike oval, either ſolitary and ſeſſile hanging down within the floral leaf, or elſe, as more frequently happens, two together, and then the ſecond on a ſhort peduncle iſſues from its own leaf, flowers later, and depreſſes the firſt. Flowers erect, cloſely imbricate. Calyx very villoſe, pale yellow with ſtreaks a little darker: teeth pale green, the two upper equal and ſhorter than the tube of the calyx, the two lower alſo equal but a little longer than the two upper ones, and for the moſt part equalling the tube of the calyx, the loweſt as long as the tube of the corolla, twice as long as the next teeth and ſometimes longer. Corolla inodorous, the whole dark purple: wings ſcarcely ſhorter than the banner, but a little longer than the keel.

It agrees in ſtature and habit moſt with the *rubens*, *montanum* and *pannonicum*. But the firſt has the ſheaths inflated and the ſtipules ſubſerrate and much bigger; the leaflets ſpinuloſe, the veins running out into little hooks, turned towards the tip of the leaflet, alternately ſmaller; ſpikes long and peduncled; calyx ſmooth, with the four upper teeth dilated at the baſe and very ſhort, the lower pair a very little longer than the upper, the loweſt filiform, the length of the whole corolla, and at leaſt three times as long as the next.

Tr. montanum has the ſtems angular-ſtreaked and many-flowered; leaflets the ſame as in the *rubens*; ſpikes peduncled; calyx ſmoothiſh, with the four upper teeth equal, and the loweſt a little longer; corollas four-petalled and white, with an awl-ſhaped banner.

Tr. pannonicum has the ſtems ſomewhat angular, and often branched; ſtipules awl-ſhaped and ciliate; leaflets villoſe on both ſides, obſcurely veined; ſpikes larger, peduncled; the four upper teeth of the calyx almoſt equal, or the two lower a little longer; corollas whitiſh.—*Tr. ochrolaucum*, which reſembles *pannonicum* very much, differs, among others, in the ſame circumſtances [o].

Cluſius is the firſt who mentions the *Trifolium alpeſtre*, in his hiſtory of Hungarian and Auſtrian plants. But we are indebted to profeſſor Jacquin for a juſt idea of it from his figures and deſcriptions. Mr. Afzelius has extricated the confuſion of ſynonyms, in his elaborate treatiſe on this ſpecies, *Tr. medium* and *pratenſe* [p].

Tr. alpeſtre is not a native of Britain, but is found in dry mountainous woody places, in Hungary, Auſtria, Bohemia, Moravia, Stiria and Piedmont [q].

It is not cultivated, nor can it be recommended for that purpoſe, ſince it affords few leaves, and does not branch.

24. Root perennial, woody, brown. Leaflets oval-oblong, narrow, quite entire, pointed or blunt emarginate, on a petiole ſpringing from a ventricoſe, ſtriated, embracing ſtipule. Spike elegant, terminating, cloſe, ovate-oblong, compoſed of numerous flowers: tube of the calyx ten-ſtreaked, yellowiſh except the teeth which are green, theſe are awl-ſhaped, and the loweſt is much longer than the reſt: corolla whitiſh, monopetalous; banner oblong, flat, upright, much longer than the wings, which are ſpreading, and the keel. Spike peduncled. Stem, calyx and leaves covered with a white cloſe ſoft ſhining down of villoſe hairs. In habit it agrees with the *rubens*, from which it differs in being ſo extremely villoſe, in having no leaves ſeſſile in the ſtipule, and in the leaflets being quite entire. It is eaſily diſtinguiſhed from the *montanum* by the form of the flowers and ſpike [r]. For the difference between this and the *alpeſtre* ſee that ſpecies.

Native of Lower Hungary, in the neighbourhood of Schemnitz, in moiſt meadows; flowering in july and auguſt.—Introduced in 1775, by Joſeph Nicholas de Jacquin, M. D. [s]

25. Root annual. Habit of *Tr. pratenſe*. Uppermoſt leaves oppoſite, ſomewhat hairy, lanceolate or oval, emarginate. Spikes terminating, ovate. Calyxes not very villoſe, five-toothed; teeth naked, briſtle-ſhaped, four erect, the fifth three times as long as the reſt and bent back, whence the ſpike becomes ſquarroſe and hooked. It varies with oval and lanceolate leaves [t].

Native of Spain. Introduced in 1778, by Monſ. Thouin. It flowers here in july [u].

26. Stem from a foot to eighteen inches in height, erect, villoſe. Stipules membranaceous, ſtriated. Leaflets roundiſh, villoſe, frequently emarginate or retuſe, from the baſe to the middle entire, and thence to the end finely notched. Spike ovate-oblong, ſoft and ſilky: when the ſeeds are ripe bent in on one ſide. Calyx villoſe, ſhorter than the corolla; teeth awl-ſhaped, nearly equal, feathered. Corolla a little longer than the calyx, red, with a long, narrow, obtuſe banner. Ray ſays that he obſerved it about Naples with beautiful red flowers almoſt ſcarlet, but that about Geneva they were of a pale fleſh-colour. According to Desfontaines they are roſe-coloured, varying to a pale red. Mr. Curtis deſcribes them of a bright crimſon; but obſerves that they are doubtleſs found with different ſhades of colour, and ſometimes wholly white [x]. Legume in the belly of the calyx, ovate, membranaceous, very thin, compreſſed at the top. Seed one, elliptic-kidney-form, yellowiſh [y].

This is an annual Trefoil, and one of the largeſt and moſt ſhowy. It flowers with us in july. Ray ſays that the ſeed is ripe and falls in july and auguſt, in Italy, where it grows naturally. It is alſo a native of the South of France, and of Barbary about Algiers. Haller reports that it has been looked for in vain near Geneva [z].

The *rubens* of Miller cannot be the *rubens* of Linneus. Retzius ſuppoſes it to be a variety of the *incarnatum*; and deſcribes it as having the leaves by no means crenulate, but entire and rather wedge-ſhaped than obcordate (as in Curtis's figure), the corolla monopetalous, of the ſame colour as in *Amaryllis formoſiſſima*; the calyx hiſpid all over, the filaments thickened at top, eſpecially the loweſt, which is alſo longer.

It appears from Parkinſon that Tr. incarnatum was cultivated here in 1640 [a].]

Mr. Miller ſays it will make good food for cattle, but being an annual, will not ſuit with the common practice of farmers.

27. [Root perennial, branching at top ſo as to bear ſeveral ſtems, each of which is upright, ſtiff, from a foot to eighteen inches in height, round, hairy, branched but not much, often tinged with purple. Leaves remote, the uppermoſt or floral ones only oppoſite, with the leaflets linear-oblong, thoſe on the ſtem large, ovate-oblong, on long petioles, the lower ones ſhort and obcordate; all the leaflets ſeſſile, quite entire, hairy on both ſides, ſoft, often purple at the edges. Stipules large, combined, embracing, ſharp-pointed, downy, ribbed with ſimple nerves. Heads of flowers terminating, ſolitary, peduncled, erect, roundiſh or ovate. Calyx ſlender, furrowed, hairy, permanent, whitiſh; teeth briſtle-ſhaped, the loweſt thrice as long as the four others, which are equal, tipped with purple, and ſometimes wholly of that colour. Petals narrow, joined at the baſe: banner very long, lanceolate, ſtraight; wings and keel much ſhorter, equal, of a pale buff or faint ſulphur-colour, by which this ſpecies is known at once from all others of Britiſh growth. Legume membranaceous, thin, tender, one-ſeeded, covered with the calyx.

Native of France, Switzerland, Auſtria, Sileſia, Italy and England, in dry paſtures, thickets and buſhy places in a gravelly or calcareous ſoil. It is common near Cambridge, and in ſome parts of Eſſex, as about Dunmow, and Caſtle Hedingham, in Hert-

Digitized by Google

fordſhire, Bedfordſhire, about Clapham, near Stamford, about Bungay in Suffolk, Dupper's-hill near Croydon, about Barnet, &c. flowering in june and july.

This Trefoil is harſh, ſtiff and hairy; and not abounding either in ſtalks or leaves, can hardly be ſought for cultivation, when there are ſo many ſpecies ſuperior to it. Mr. Curtis recommends it to the notice of the experimental agriculturiſt, and thinks it may be a good ſubſtitute for the *repens* or *pratenſe*, in certain ſoils and ſituations. I rather agree with the author of Engliſh Botany, that it is in no reſpect worthy of attention as an object of culture. It appears how much this ſpecies is attached to a dry ſoil, from Mr. Curtis's information, that he never could keep it in his garden at Lambeth marſh [b].

Mr. Miller has unaccountably confounded this, with what is commonly ſown under the name of Trefoil or Nonefuch, *Medicago lupulina*.

28. Root annual, woody, hard. Stems numerous, erect, ſtiff, villoſe and ſilky, a foot high, branched or ſometimes ſimple. Leaflets linear or linear-lanceolate, an inch long or three times as long as the peduncle, white and ſilky, acute, ſpringing from a widened membranous petiole, which ends in two long briſtle-ſhaped ſtipules. Spike terminating, oblong, ſhorter than the leaves, denſe with ſmall pale purple flowers, almoſt concealed by the diviſions of the calyx, except the banner which is erect. Calyx villoſe and ſilvery with the loweſt diviſion longer than the reſt [c].

Leers compares it with the *arvenſe*; from which he ſays it differs in having a higher and more upright ſtem, ſomewhat four-cornered, ſmooth not pubeſcent; branches much ſhorter than the ſtem; ſtipules nerved and more acuminate; leaflets narrower, ſmooth on both ſides, ſtriated beneath; heads ſubcylindrical, narrower, longer; calyxes ſtriated, with the teeth purple and naked not feathered, the three lower a little longer than the two upper; corollas ſhorter than the calyx, pale or whitiſh, without the blood-red ſpot in the wings. Receptacle naked not villoſe.

According to Linneus it varies in Paleſtine with corollas double the common ſize, and more deeply coloured; the lower tooth of the calyx longer, and all of them ſtraight, not bent in.

Native of Germany, the South of France, Italy, Spain, Carniolia, Barbary, and the iſland of Madeira. —Cultivated in 1739 by Mr. Miller. It flowers from june to auguſt [d].

29. Root ſmall and annual. The whole plant villoſe. Stem moſtly erect, much branched, round, firm, changing its direction from joint to joint. Leaves on ſhort petioles: leaflets nearly ſeſſile, linear-obovate, the lower ones elliptical, the upper nearly linear, ſomewhat emarginate, and the midrib lengthened into a ſhort point. Stipules lanceolate, often ſtriated with red veins, and tapering into a briſtle-like point. Heads or rather ſpikes cylindrical, blunt, various in length, denſe, conſiſting of numerous pale-reddiſh flowers, the long tapering equal prominent ſtriated very hairy calyx-teeth of which give the whole ſpike a downy appearance. Corolla much ſhorter than theſe teeth, and almoſt concealed by them. Pod very ſmall [e]; membranaceous, ovate, equal to the belly of the calyx. Seed one, elliptic-globular, of a yellowiſh green colour [f].

Native of Europe and Barbary, in barren ſandy paſtures and fields; flowering in july and auguſt.

Far from being worthy of cultivation for fodder, like moſt of the genus, this appears to be altogether a weed, nor are we acquainted with any animals that prefer it as food.

β. In maritime ſituations the herbage ſometimes becomes quite ſilky [g]. Dillenius, who figured it in his edition of Ray's ſynopſis, ſays that the root runs deep, that the ſtems are procumbent, from one to three inches long, that the heads are numerous roundiſh ſoft and ſhining, on very ſhort peduncles, and that the flowers are white or pale fleſh-coloured.

Mr. Woodward remarks, that the leaflets are rather elliptical and blunter than in the common ſort, the ſtipules more villoſe, the flowering heads nearly ſpherical and containing fewer flowers, and the briſtles of the calyx green. Dillenius's figure has the flowering heads too numerous, and too large for the proportion of the figure, the leaves are alſo too pointed.

Lobel firſt found it near South-Sea Caſtle, Dillenius near Brackelſham in Suſſex, Mr. Woodward on Yarmouth Danes, at Loweſtoft, &c.

30. Root annual. Stems many, ſpreading, often decumbent, or erect only when they grow in a tuft, varying in height, but commonly near a foot high, round, ſtriated, a little hairy, branched. The uppermoſt or floral leaves only oppoſite; all on footſtalks: leaflets obovate, almoſt quite entire, being minutely notched at the tip only, of a darkiſh green, hairy. Stipules linear, very narrow, the point awl-ſhaped, elongated and hairy. Flowering ſpike terminating, ſolitary, commonly peduncled, ſmall, cloſe, ſhort, blunt, oval or almoſt globular. Calyx tubular, hairy eſpecially at the top of the tube; divided almoſt to the baſe into five ſegments, which are ſlightly unequal in the flower, but more ſo in the fruit, and then become broad and ſpreading. Corolla nearly equal, pale purple. Legume turbinate, one-ſeeded [h].

Mr. Woodward remarks, that the ſtipules are lanceolate, lengthened into a very long point, ſtriated, and fringed with long hairs; the lower leaflets oblong wedge-ſhaped, the upper between that form and lanceolate; the fruitſtalks longer than the leafstalks; the ſegments of the calyx between lanceolate and ſubulate, as long as the corolla, fringed with long hairs; banner lanceolate, keeled, longer than the wings, which are hooked very near the baſe, and equal to the keel.

It grows in ſalt-marſhes and meadows near the ſea in various parts of England, from Norfolk all along the ſouth and weſt coaſt to Wales. Mr. Wigg ſent it from Yarmouth, and Sir Thomas Gery Cullum from Weymouth [i]. Dartford Saltmarſh. Leigh and Little Holland, Eſſex. Tilbury Fort. Sheerneſs. Between Greenhithe and Northfleet. Between Briſtol and the Hot-wells, obſerved by Mr. Swayne [k], near Weymouth, Poole, &c. in Dorſetſhire by the late Dr. Pulteney. Dr. Johnſon, the editor of Gerarde's herball, firſt found it on Dartford Saltmarſh in Kent, the tenth of june, 1633.

Mr. Hudſon rightly publiſhed it as new in the firſt edition of his Flora Anglica, and ſent it to Linneus, in whoſe herbarium it now is marked Hudſon's *T. maritimum*, without referring it to any of his own plants, and yet he neglected to inſert it in any of his ſubſequent works. It is difficult to gueſs why Mr. Hudſon afterwards took this plant for *T. ſtellatum*, a very different ſpecies [l], as will evidently appear from comparing the figure of the *maritimum* in Engliſh Botany, *t.* 220, with that of the *ſtellatum* in Flora Ruſtica, *t.* 94.

Ray ſays that he obſerved this Trefoil about Meſſina in Sicily; and that Balam ſent it from Tangiers in Africa.

31. Root annual. The whole plant villoſe. Stem erect, branching. Leaves on long petioles: leaflets obcordate, toothletted, nerved. Stipules large, netted-veined, ovate, toothed. Heads or rather ſpikes of flowers ovate, peduncled. Calyxes villoſe, ſoft; teeth very long, awl-ſhaped, nearly equal, ſilky, when the ſeeds are ripe ſpreading. Corolla pale roſe-colour, ſhorter than the calyx [m]. Legume within the belly of the calyx, ovate, membranaceous, very thin. Seed one, elliptic-kidney-ſhaped, rufeſcent [n].

Native of the South of France, Carniolia, Italy, Sicily, Barbary. Ray obſerved it growing abundantly

Digitized by Google

at the foot of Mount Veſuvius, in Sicily about Meſſina, and near Montpellier in France.

32. Root annual. Colour of the plant white or ſilvery. Named *clypeatum* by Alpinus from the form of the fruiting calyx ſpread out like a ſhield.

The Legume lies hid in the furrowed belly of the five-rayed-peltate cloſed calyx; it is ovate, compreſſed, truncate at the top, and there headed with a whitiſh ſpongy callus, membranaceous, very thin, one-celled, not opening. Seed one, ovate, compreſſed, ſomewhat gibboſe, ſmooth, ferruginous[o].

Native of Italy and the Levant. Cultivated here in 1711. It flowers in july and auguſt.

33. Root annual, ſmall. Stems ſeveral, proſtrate, rigid, often a little flexuoſe, round, rugged, leaflets obovate or obcordate, toothed, veiny, hairy. Stipules ſcarioſe, lanceolate, connate, hairy. Heads axillary and terminating, ſolitary, ſeſſile, ovate, hairy, compoſed of many thick-ſet, white or pale bluſh-coloured flowers. Calyx hairy, with a pale furrowed baſe, and green ſharp lanceolate teeth, erect at firſt, but ſoon ſpreading, and at length recurved, hard, and rigid. Corolla longer than the calyx. Pod membranous, whitiſh, incloſed in the calyx. Seed one, elliptic, ſhining, yellowiſh[p].

Native of ſeveral parts of Europe, as Germany, Switzerland, Carniolia, South of France, Italy, Britain; alſo of the hills about Algiers in Barbary. With us it is found occaſionally on chalky ground, or in dry ſandy fields that lie over a calcareous ſoil, where it flowers in may and june, and then ſoon dries up and is blown about, ſcattering its ſeeds againſt the autumnal rains, when they produce young plants which flower the following ſpring. It occurs between Northfleet and Graveſend, near Chatham and in the Iſle of Shepey; about Croydon in Surry; on Newmarket-heath, about Chippenham and Gamlingay in Cambridgeſhire, and near Cambridge on the Hill of Health, and Trinity Conduit-head. Near Oxford, by Jericho, on the road ſide going to Port Meadow. Potton, Sandy and Ampthill, Bedfordſhire, by Dr. Abbot. Near Bungay, by Mr. Woodward. On Caiſter common near Norwich, on Cromer cliffs, on Snettiſham beach and near Wells, by Mr. Crowe. On Wick cliffs, by Mr. Swayne. Near Edinburgh, by Dr. Parſons.

34. Root annual, ſmall, fibrous with oval fleſhy knobs. Whole plant quite ſmooth. Stems proſtrate, ſtriated, of various lengths, not much branched. Leaves remote, alternate, on petioles which are grooved above: leaflets obovate or oblong-wedge-ſhaped, often marked with a tranſverſe white or yellowiſh ſpot, ſtrongly nerved, the branches from the midrib terminating in neat acute ſerratures, ſcarcely diſtinguiſhable by the naked eye, and in the younger leaves the midrib only is lengthened into a projecting point. Stipules membranous, broad-ovate, pointed, divaricated, united at the baſe. Heads axillary, ſolitary, ſeſſile, hemiſpherical, many-flowered. Calyx ſwelling, pale with ten red ribs, ſhorter than the corolla; teeth heart-ſhaped, pointed, ſmooth, veiny, which become at length reflexed and enlarged, ſufficiently diſcriminating the ſpecies. Corolla pale red or roſe-coloured: banner lanceolate, ſomewhat keeled, longer than the wings; they and the keel are equal. Pod round, ſmall, holding a ſingle ſeed[q]. According to Gærtner it contains two ſeeds, of an ovate-globular form, and of a pale ſulphur-colour: the pod is oblong, compreſſed a little, membranaceous and diaphanous, involved in the corolla.

Mr. Curtis remarks, that it may be diſtinguiſhed from the *ſtriatum*, to which it bears ſome affinity, by being in every part ſmooth, in having its heads much rounder, and the teeth of the calyx ſpreading backward; its flowers alſo are of a brighter red colour.

Native of England, Spain, Italy, and Barbary about Algiers. With us it does not appear to be very common. Ray found it about Saxmundham in Suffolk, and Thomas Williſel brought it him from the neighbourhood of London. Mr. Doody gathered it about Blackheath and near Greenhithe, Mr. Hudſon, in the Iſle of Shepey. Mr. Roſe and Dr. Smith, near Norwich. Mr. Woodward, on the Bath hills near Bungay in Suffolk. Mr. Turner, at Yarmouth. Dr. Goodenough, on Kew-green and Hanwell-heath. Mr. Curtis obſerved it on Blackheath for ſeveral years, and ſays it is fond of a gravelly ſoil, with ſome degree of moiſture. It flowers about midſummer.

35. Root annual. Stems procumbent, branched, round, villoſe: according to Mr. Woodward, from ſix to eighteen inches high, moſtly erect, but if reclining not proſtrate, as in the two foregoing ſpecies. Leaflets obovate or obcordate, hairy. Stipules broad-ovate, acuminate, nerved, membranous. Heads moſtly terminating, ovate. Calyx elliptic, ſomewhat ſwelling, ten-grooved, villoſe; teeth awl-ſhaped, green, finally elongated, ſpreading, ciliate. Corolla ſcarcely the length of the calyx, pale purple. Pod membranaceous. Seed elliptic, compreſſed, three times as large as in the foregoing[r].

Mr. Woodward deſcribes the leaves as diſtant, the upper on ſhort, the lower on long footſtalks, thoſe beneath the heads ſeſſile or nearly ſo: leaflets ſeſſile, lower ones oblong-wedge-ſhaped, upper lanceolate, downy on both ſurfaces; the nerves not ſtrongly marked, and the ſerratures ſcarcely diſtinguiſhable even with a glaſs. Stipules ovate, but terminated with a point, ſtriated and very downy. Flowering-heads ſeſſile or on ſhort peduncles, axillary or terminating, the latter moſtly in pairs. Calyx little ſhorter than the corolla, marked with ten ſtreaks, almoſt hid with numerous long ſoft hairs; teeth nearly equal, ſtraight, awl-ſhaped, not rigid. Corollas pale red: banner lanceolate, longer than the wings; they and the keel equal. The flowering heads appear quite woolly from the numerous long hairs of the calyx.

Native of Britain, Germany, France, Spain and Italy, in dry barren paſtures. In ſeveral places near Cambridge, and about Gamlingay. Biddenham and Aſpley in Bedfordſhire, Dr. Abbot. Jericho, Bullington-green, and Whichwood-foreſt in Oxfordſhire, Dr. Sibthorp. Bath-hills, Bungay, Suffolk, Mr. Woodward. Wick Cliffs, Mr. Swayne. In Edinburgh-park, abundantly, Mr. Lightfoot. It flowers in june.

36. Root annual, tapering, without any tuberous ſwellings. Stems horizontal, ſhort and twiſted, moſtly under ground. Leaves on very long footſtalks; leaflets obovate or wedge-ſhaped, ſmooth and finely toothed. Stipules membranous, broad, with remarkably ſpreading points. Flowers in ſeſſile axillary round heads. Body of the calyx a little hairy: teeth bent back, broad, acute, ſcarcely enlarged after flowering. Corolla much ſhorter than the calyx-teeth, cloſed ſo as to protect the organs of fructification, which therefore perform their functions though buried in ſand. The excluſion of light often renders the petals whitiſh, otherwiſe they are roſe-coloured. Pod oblong, containing two yellowiſh ſeeds, which are lens-ſhaped, and rugged at the edge.

This, more truly a ſubterraneous plant than the ſpecies ſo named by Linneus, grows in the looſe blowing ſand of the ſea-ſhore, beneath which its ſtems and flowers are often entirely buried, the leaves only peeping above the ſurface. Hence the trivial name, and hence perhaps it has been overlooked, as ſome common ſpecies not yet in flower.

It has been long known as a native of Sicily, where Ray obſerved it about Meſſina. Mr. Wigg firſt detected it on the beach at Yarmouth: and ſince that Miſs Temple has found it at Loweſtoft, and the late Mr. W. R. Notcutt, and Sir Thomas Gery Cullum at Landguard-fort. It flowers in june and july.

Linneus placed this ſpecies in the laſt ſection of the genus, among his *lupulina*; but I have followed Dr. Smith in putting it in the third ſection, with the *glomeratum*, *ſtriatum*, &c. to which it is evidently allied[s].

37. Heads ovate. Loweſt ſegment of the calyx a little longer than the others[t]. Native of Egypt.

38. Leaves toothletted. Pedicels long, with the flowers remote. Calyxes with long tubes, ten-ſtreaked, equal [u]. Native of Syria, Judea, Arabia, abundant about Conſtantinople, Candia [t].

39. Calyxes terminated with five briſtles. Corollas red. Legumes longer than the calyx, awl-ſhaped at the end, filling the calyx, four-ſeeded [x].

Fruiting-calyx ovate-oblong, ſwelling, membranaceous, netted, terminated with five briſtle-ſhaped teeth, recurved and ſpreading. Corolla ſhrivelling, lacerate, permanent, involving the legume; which is oblong, membranaceous, very thin, and ends in the briſtle-ſhaped ſtyle. Seeds four (or two larger), ſubglobular, covered with very minute raiſed dots, ſulphur-coloured, or deep yellow, or ferruginous [z].

Native of France and Italy. Introduced in 1771 by Monſ. Richard. It flowers in june and july [a].

40. The corolla is turned upſide-down, ſo that the banner reſpects the periphery, and the keel the centre. Calyx inflated, ovate-oblong, terminated with two briſtles, having a very ſhort one between them, and gaping longitudinally on the lower ſide. Legumes two-ſeeded, roundiſh, very ſmall, in the bottom of the calyx [b].

Fruiting-calyx ovate-beaked, inflated, gibbous, membranaceous, netted, terminated with two briſtle-ſhaped hooked teeth, quite entire at the back, but having a longitudinal cleft in the belly. Legume very ſmall, obovate, membranaceous, very thin. Seeds two (ſometimes, but ſeldom, one), ovate, ſmooth, of a yellow bay colour [c].

Native of Belgium, Sileſia, the South of France and Italy. Dr. Smith obſerved it the ſecond of april on the ſteps of Trinita de' Monti, at Rome; and ſays he knows not on what authority Linneus has made it a native of England [d].

41. Root perennial. Stems decumbent all round, not creeping. Leaves obovate, toothletted, obtuſe, ſmooth, with acuminate ſtipules. Peduncles axillary, very ſhort. Heads ſmall. The three upper teeth of the calyx elongated, the two lower ſmall. Calyx involved in ſo thick a nap as not to be viſible. General involucre twelve-leaved. Corollas almoſt reſupinate [e].

Native of the South of Europe, and of Barbary. Cultivated in 1640, by Mr. John Parkinſon. It flowers in june and july [f].

42. The whole plant is hirſute. Stems erect. Stipules ovate, ending in an awl-ſhaped point. Leaflets toothletted, nerved. Head of flowers roundiſh. Involucres three or four, rounded, involving the baſe of the head, one of them three-leaved. Calyx-teeth long, equal. Corolla roſe-coloured: banner awl-ſhaped. Native of Barbary near Maſcar.

43. Plant villoſe. Stipules ovate. Leaflets obcordate or obovate, nerved. Involucre four-leaved, preſſed cloſe; leaflets rounded, ſtriated; one of them three-leaved. Segments of the calyx long, villoſe. Corolla very ſmall, white. Native of Barbary near Maſcar [g].

44. Root perennial, fibrous with little tubers. Stems proſtrate, rooting, extending to a conſiderable length, often tinged with purple, branched, round, and ſmooth. Leaves on long petioles: leaflets obovate, toothletted, ſmooth; the younger ones ſometimes hairy. Stipules ovate-lanceolate, drawn out into a long point, ſmooth. Peduncles ſolitary, axillary, naked, round, ſmooth, aſcending, longer than the petioles. Heads globular, many-flowered. Involucre conſiſting of many briſtle-ſhaped leaflets. Calyx tubular, villoſe, gibbous above; the three lower teeth equal, with long green points, the two upper a little longer, with tapering rigid reddiſh points; the gibbous part at length increaſes, ſwells, becomes reticulated, and covers the pericarp, ſtill retaining its teeth. Corolla purple: banner longer than the wings, flat and ſtreaked with roſe-coloured lines; wings ſhort and ſmall; keel ſtill ſhorter: each floret is attended by a ſmall, awl-ſhaped, concave chaff. Legume ovate, flattened, containing two ſeeds, of an ovate kidney ſhape and ſhining, covered by the calyx [h].

The ſingular Strawberry-like appearance of the heads, ariſing from the inflation of the calyx after flowering, ſtrikingly diſtinguiſhes this ſpecies from the *repens*, to which in its general habit it is nearly allied: the whole plant alſo of the *fragiferum* is ſmaller, the corolla is purple, and it uſually occurs in moiſt ſituations [i].

Native of all parts of Europe, flowering in july and auguſt.

45. Root perennial, running down deep. Stem upright, eight inches or a foot and more in height, hardiſh, round, whitiſh-green, pubeſcent, ſomewhat rugged, ſimple except that at the end it breaks into two or three branches, ſuſtaining flowers. Lower leaves on longer, upper on ſhorter petioles and almoſt ſeſſile: leaflets lanceolate, acuminate, nerved, hard, very finely ſerrulate, tranſverſely ſtriated, bright green, villoſe beneath, ſomewhat rugged. Stipules lanceolate, ſtriated, awl-ſhaped, pubeſcent. Peduncles axillary, thick, grooved, pubeſcent. Flowering heads large, ovate, obtuſe, the ſame ſize as in the *alpeſtre* but white, and compoſed of an hundred or more ſeſſile florets. In *ſyſtema vegetabilium* the head is called a raceme, which is ſqueezed cloſe, and has very ſmall awl-ſhaped bractes between the florets. Calyx ſmooth or ſubpubeſcent; teeth almoſt equal. Corolla white, of four diſtinct petals: banner lanceolate, obtuſe, ſlightly emarginate, twice as long as the wings and keel; wings obtuſe, ſpreading, a little longer than the keel, which is ſtraight and obtuſe. Legume from orbicular inclining to ovate, flattiſh, ſmooth, ſharp at the edge, involved in both calyx and corolla. Seed one, ſmall, roundiſh-ovate, blunt at both ends, yellowiſh-brown, ſmooth [k].

Native of many parts of Europe, on very dry hills, from Sweden to Spain; but not of England, which Linneus remarks as a ſingularity, it being ſo common in Sweden.—It was introduced here in 1786, by William Pitcairn, M. D. and flowers in july [l].

Scopoli relates, that he has gathered a variety, which was more villoſe, with the teeth at the edges of the leaves ending in a kind of ſpinule, and the flowers of a whitiſh yellow colour.

46. Root annual. Stems nearly upright, ſolitary. Calyx before flowering ſcarce apparently hairy, having only a hair or two at the tips. Corollas yellow not bay-coloured [m]: the flowers are permanent, and when dry make a ruſtling noiſe, whence Crantz's name of *ſtrepens*.

Native of many parts of Europe, in paſtures. Dr. Smith obſerved it on the top of Mount Cenis. It is not a native of England. What has been taken for it is the *procumbens*, n. 48.

47. This has the appearance of the ſpecies immediately preceding, but the ſtem is more erect and ſolitary: the banner of the florets becomes ferruginous after flowering; the two upper teeth of the calyx are indiſtinct in this, whereas in the preceding they are of the ſame length with the others [n].

Native of ſeveral parts of Europe, in dry paſtures, but not of England.—Introduced in 1778, by Mr. Thouin. It flowers from june to auguſt [o]. In the Kew Catalogue it is marked as perennial; and Monſ. Villars ſays, it has always appeared to him to be ſo. This author has adopted Pollich's *Tr. aureum*, *n.* 708. which is nearly allied to the *ſpadiceum*, but the ſtem is more ſlender, higher, and more branched.

48. Root annual, ſmall but ſtrong. Stems ſpreading widely and naturally procumbent, though ſometimes ſupported by other plants, and indeed generally aſcending at their extremities; they are a little branched, leafy and hairy, often purpliſh. Leaflets obovate, emarginate, toothed, ſmooth. Stipules half-ovate, acute, entire, ſtrongly ribbed, often ciliate.

Flowering-heads peduncled, a little ſpicate, frequently reaching beyond the leaves, elliptical, obtuſe, denſe, many-flowered. Peduncles moſt hairy upwards. Calyx-teeth unequal, taper, hairy. Corolla lemon-coloured, permanent, at length brown and membranous: banner broad, furrowed, plaited. Pod ſmall, elliptic, pointed[p]. Seed ſingle, ſhining, of a brown or orange colour.

The name of Hop Trefoil is, with much propriety, beſtowed on this plant, the heads being larger and more reſembling the hop than any of our Engliſh ſpecies. It is by no means uncommon in dry paſtures, on the borders of fields, and in gravelly ſoils. In ſome meadows it forms a conſiderable part of the crop, and makes excellent fodder. It flowers in june and july, and perhaps merits the attention of the huſbandman[q]: where its laſting only one year is no objection.

According to Linneus, the *procumbens* differs from the *agrarium* and *ſpadiceum* in having ſmaller flowers, but eſpecially becauſe its long ſtalks are altogether decumbent. It reſembles the *filiforme*, but is larger, and has often ten or twelve flowers. The leaves are not ſtriated. On being ſown it was alſo different from that[r]. Leers ſays, there are often two ſeeds in a pod.

The ſynonyms given by Linneus to the *agrarium* belong to this ſpecies, except that of Dodonæus, which is *Medicago lupulina*. The *procumbens* of Engliſh authors is conſidered by Linneus only as a variety of the *filiforme*[s]. Dr. Smith however ſays, he is now convinced that the *procumbens* of Hudſon is improperly confounded with *filiforme* in Flora Britannica.

49. Root annual, ſmall, fibrous. Stems proſtrate, filiform, ſomewhat hairy. Leaflets obcordate, toothed, ſtriated. Stipules ſubovate, nerved, ciliate. Peduncles axillary, capillary, hairy, (in α ſcarcely four-flowered, in β many-flowered), flowers erect, in a ſort of head, pedicelled, yellow, finally bent back. Calyx ſmooth, with unequal teeth. Corolla permanent, ſcarioſe, browniſh, with the banner keeled, narrower than in the preceding, neither bent in nor grooved. Legume elliptic, pedicelled, one-ſeeded[t].

50. When this grows luxuriantly it bears a near reſemblance to the *agrarium*, but in that the ſpikes are not only much larger, but alſo much more cloſely imbricated; the *procumbens* is found only in certain ſpots, whereas there is ſcarcely a dry hilly paſture or graſs plat on which this may not be found[u].

This, ſays Dr. Withering, is the moſt common ſort of Hop Trefoil, and may be found in almoſt every dry ſandy or gravelly paſture, eſpecially where the turf is fine, but varying greatly in ſize, according to the richneſs or poverty of the ſoil, and flowering from may to auguſt.

51. Stem nearly upright. Leaflets lanceolate, on ſhort petioles. Stipules ſheathing, with two acuminate teeth, the length of the ſheath. Heads axillary, funnel-form, ſeſſile, wrapped up in ſeveral leaves which are ſlightly trifid, the middle ſegment longer than the others. Flowers two, coming out alternately. Native of Virginia, and Canada[x].

In this extenſive genus the following diſtinctions may be of uſe in diſtinguiſhing the ſpecies.

Reſpecting the infloreſcence, the following ſpecies are

Racemed: 1 to 8 and 45 to 49.
Umbelled: 9, 10. 12 to 15.
Faſcicled: 16, 17. 50.
Headed: 18, 19. 32 to 44.
Spiked: 11. 20 to 31.

All the ſpecies, as the name implies, have ternate leaves, except the ninth, in which they are uſually quinate or five together.

More ſpecies are annual than perennial:

Annuals are from 1 to 8. 11. 16 to 19. 25, 26. 28 to 36. 46 to 50.

Perennials: 9. 12 to 15. 20 to 24. 27, 41, 44, 45.

The predominant colours of the flowers are yellow and purple,

Yellow. 3, 4, 5, which varies to white; 6, 7, 18? 41, 46 to 50.
Yellow or White. 2.
Pale Brimſtone. 27.
White. 11, 12? 13. 16. 43. 45.
Whitiſh. 24. 33.
Purple. 9, 10, 15, 19? 20 to 23, 25, 28, 40.
Red. moſtly pale. 8, 26, 29, 30, 31, 34, 35, 36, 42.
Blue. 1.

Moſt of the flowers have one ſeed only in each legume or pod.

Seed one: 16, 17, 20 to 33, 35, 45 to 50.
Seeds one or two: 2, 5, 6, 7, 34.
Seeds two: 4, 11, 36, 40, 44.
Seeds two or three: 10.
Seeds two to four: 1, 13.
Seeds four, 12, 14, 39.
Seeps four or five: 9.
Seeds eight: 8.

Some of the legumes which have naturally one ſeed only, have occaſionally two ſeeds.

Several of the ſpecies have the banner, wings and keel connected at the baſe, and are therefore called monopetalous by Linneus.

This is the proper place to acknowledge the aſſiſtance of Mr. Afzelius in clearing up the confuſion of ſynonyms in ſome of the ſpecies: as alſo to confeſs and correct the errors committed in the Flora Ruſtica. —What was ſuppoſed in that work to be *Trifollum medium*, is *Trif. pratenſe* in its wild ſtate. What is there named *Tr. flexuoſum* is the *Tr. medium*. *Tr. alpeſtre* is not a native of Scotland. The figure of *Tr. ſtellatum* is a very good one, but the deſcription does not belong to it.]

PROPAGATION AND CULTURE.

1 to 8. If the ſeeds of the Melilots, which are annual* plants, be permitted to ſcatter, the plants will riſe without care, and require no other culture but to be kept clean from weeds, and to be thinned where they grow too cloſe.

There are few worſe weeds among corn than common Melilot, for the ſeeds being ripe about the ſame time with the corn, they are threſhed out with it, and being heavy are difficult to ſeparate from it. A few of the ſeeds, as is well known, give the flour a ſtrong nauſeous taſte.

[But as a food for cattle Melilot may have its value. It has been recommended by ſome French writers, as ſucceeding well in a ſandy ſoil for this purpoſe. Particularly the White Siberian Melilot, which is conſidered by Linneus as a variety of the common ſort. It grows in Siberia, in deep light dry land, and riſes from three to nine feet in height. It dies to the ground in winter, but ſhoots again early in ſpring, and laſts from two or three to ſix years. It begins to flower about the middle of june, and is in full bloom the middle of july.

Although the ſtems and leaves of Siberian Melilot are twice as large as thoſe of the common ſort, the flowers are but half the ſize, and are conſtantly white. It has been ſown twenty years by the ſide of common Melilot, in the Paris garden, without varying. Sown in the field, on a light ſoil, but wet, it grew above eight feet high, and produced a great quantity of ſeed; it was given to cattle both green and dry, and they preferred it to every other food, eſpecially when freſh cut. In a looſe dry ſoil it will riſe to ſix feet high. In ſuch land it may be ſown in autumn, upon one earth; but in wet land it is ſafer to ſow it in ſpring, at which time the land muſt have two earths and be well broken with the harrow. The ſeed being ſmaller than that of Clover, and the plant ſpreading more, half the quantity of ſeed uſually ſown of Clover will be ſufficient.

Siberian Melilot ſown in autumn, may ſometimes be mowed in november, then in may, again in july, and laſtly in november: the firſt cuttings may be made into hay, but the laſt muſt be given to the cattle green. By means of regular cuttings, this plant may be preſerved ſeveral years; but if it be left to ripen its

[t] Smith brit. [u] Curt. lond. [x] Linn. ſpec.

Digitized by Google

its ſeed, it ſoon becomes weak, and may be conſidered as a biennial.

This Melilot, cultivated by itſelf, ſeems to be more productive than Clover; but the produce becomes much more conſiderable, when cultivated with the Siberian Vetch: for theſe plants poſſeſs all the qualities which can make their union deſirable: they laſt the ſame time—they ſhoot at the ſame period—they flower and ſeed together—they extend their roots to different depths—one produces a thin and tender food, the other more ſolid and ſubſtantial—laſtly, the warm quality of the one is tempered by the watery quality of the other.

Mr. Young, having been favoured with ſome of the ſeed of Siberian Melilot, by Monſ. Thouin, on the 11th of april 1791, ſowed a piece partly in drills at two feet ſix inches, and one ſquare perch broad-caſt; the latter with an ounce and half of ſeed, or fifteen pounds an acre. The ſoil a moiſt loam, on a cold marley bottom. On the 22d of ſeptember it was mowed, being a full and beautiful crop. One ſquare perch drilled weighed one hundred and five pound. The perch broad-caſt, eighty-four pound. The drilled received a ſmall manuring, at the time of ſowing, of aſhes, to the amount perhaps of about ten buſhels to the acre. But the rows were too far aſunder; and the crop in each row would probably have been as great, if the diſtance had been only eighteen inches.—A hundred and ſixty-five pound to the perch is ſeven tons and a half on an acre; and eighty-four pounds is ſix tons to the acre.

Either of theſe crops is enough to pay the loſs by not ſowing barley or oats, and to prove that the plant will pay amply for culture; the one is equal probably to above two tons of hay to the acre, and the other more than one and a half.

The ſeaſon was a ſevere drought. It was given to cows, working oxen, calves and horſes, and they all eat it very readily, ſome even greedily.

In ſtrong lands, which will bear Clover, this plant may not be found an object of culture; but in poor ſands and all ſoils not adapted to Clover, it may be ſown to advantage, as hardly any other plant ſeems to flouriſh ſo well there, and ſheep are very fond of it [r].]

13. White or Dutch Clover grows naturally in moſt of the paſtures in England, and is generally known among the country people by the title of white Honeyſuckle.

This is an abiding plant, whoſe branches trail upon the ground, and ſend out roots from every joint, ſo that it thickens and makes the cloſeſt ſward of any of the ſown Graſſes; and it is the ſweeteſt ſeed for all ſorts of cattle yet known; therefore when land is deſigned to be laid down for paſture, with intent to continue ſo, there ſhould always be a quantity of the ſeeds of this plant ſown with the Graſs ſeeds. The uſual allowance of this ſeed is eight pounds to one acre of land, but this ſhould never be ſown with Corn; for if there is a crop of Corn, the Graſs will be ſo weak under it, as to be ſcarce worth ſtanding: but ſuch is the covetouſneſs of moſt farmers, that they will not be prevailed on to alter their old cuſtom of laying down their grounds with a crop of Corn, though they loſe twice the value of their Corn by the poorneſs of the Graſs, which never will come to a good ſward, and one whole ſeaſon is alſo loſt; for if this ſeed is ſown in the ſpring without Corn, there will be a crop of hay to mow by the middle or latter end of july, and a much better after-feed for cattle the following autumn or winter, than the Graſs which is ſown with Corn will produce the ſecond year. The ſeed of this ſort may alſo be ſown with Graſs ſeeds in autumn, in the manner hereafter directed for the common red Clover; and this autumnal ſowing, if the ſeeds grow kindly, will afford a good early crop of hay the following ſpring; and if, after the hay is taken off the land, the ground is well rolled, it will cauſe the Clover to mat cloſe upon the ground, and become a thick ſward.

The ſeed of this white Dutch Clover is annually imported from Flanders, by the way of Holland, from whence it received the name of Dutch Clover; not that it is more a native of that country than of this, for it is very common in moiſt paſtures in every county in England, but the ſeeds were never collected for ſowing here till of late years: nor are there many perſons at preſent here who ſave this ſeed, although it may be done, if the ſame care as is practiſed for the red Clover, is taken with this ſort; therefore it ſhould be recommended to every farmer, who is deſirous to improve his land, carefully to ſow an acre or two of this white Clover by itſelf for ſeeds, which will ſave him the expence of buying the ſeeds, which are often ſold at a great price, and there will be no want of ſale for any quantity he may have to ſpare.

The farther account of this Graſs, may be ſeen under the article PASTURE.

[Mr. Majendie of Hedingham Caſtle, in Eſſex, has cultivated White Clover for ſeed with ſingular ſucceſs. He had ten acres that yielded him fifteen guineas an acre, clear of expenſes, the ſample of the ſeed being remarkably fine, and exceeding any foreign in the market. He ſows it with ſpring corn, from twelve pounds to fourteen pounds on an acre; and has found wheat to be as good after this as after red Clover [z].

Mr. Pitt of Pendeford in Staffordſhire, informs us that the beſt graſs ſeed that can be ſown for upland paſturage is the white Dutch Clover; that it has a great advantage over all others, from its extreme minuteneſs, on which account any given weight fills the ground proportionably fuller of plants; that theſe plants, on ſound land, will abide for ever, make excellent ſweet paſture, and may be invigorated at pleaſure by dung.

He weighed, and numbered a ſmall weight of the following ſeeds, by which he found, ſuppoſing them all good, that one pound of white Clover ſeed, gives as many plants as two pounds and a half of red Clover, ten pounds and a half of burnet, and thirty-eight pounds of ſaintfoin. Whence, ſuppoſing ſix pounds of white Clover ſeed ſufficient for an acre; to give as many plants, an acre will require fifteen pounds of red Clover, ſixty-three pounds of burnet, and two hundred and twenty-eight pounds of ſaintfoin [a].

Dr. Anderſon remarks, that the common white or Dutch Clover delights in a firm ſoil, although it does not require ſuch a degree of compactneſs as red Clover, and therefore proſpers in many fields without any artificial preſſure; but on very ſpungy ſoils, art muſt ſupply the deficiency of nature, or it will not thrive. Hence it happens, that on ſoils of this ſort, white Clover is frequently ſeen to flouriſh exceedingly on ſuch foot-paths as are moderately trod upon, while it only languiſhes, or hardly appears in other parts of the field [b].

Mr. Wright of Stanhow in Norfolk thinks that white Clover is a bitter food, and that ſheep do not eat it kindly, ſo that while much food ſeems to be on the ground, ſtock does badly. Mr. Bakewell, it ſeems, adopted this ſingular opinion [c].]

21. Since the red Clover has been cultivated in England, there has been great improvement made of the clay lands, which before produced little but Rye-graſs, and other coarſe bents; which, by being ſown with red Clover, have produced more than ſix times the quantity of fodder they had formerly on the ſame land, whereby the farmers have been enabled to feed a much greater ſtock of cattle than they could before, which has enriched the ground, and prepared it for Corn; and where the land is kept in tillage, it is the uſual method now among the farmers, to lay down their ground with Clover, after having had two crops of Corn, whereby there is a conſtant rotation of Wheat, Barley, Clover, or Turneps on the ſame land.

The Clover-ſeed is always ſown with Barley in the ſpring, and when the Barley is taken off, the Clover ſpreads and covers the ground, and this remains two years, after which the land is ploughed again for Corn.

[r] Young's Annals, 14. 217. 15. 447. and 16. 426.

[z] Young's Annals, 18. 434. [a] Idem, 4. 338.
[b] Eſſays, 2. 295. [c] Young's Annals, 12. 52.

Th

The Clover is a biennial plant, whoſe roots decay after they have produced ſeeds; but by eating it down, or mowing it when it begins to flower, it cauſes the roots to ſend out new ſhoots, whereby ſome of the plants are continued longer than they would naturally remain. The common allowance of ſeed for an acre of ground is ten pounds. In the choice of the ſeeds, that which is of a bright yellow colour, inclining to brown, ſhould be preferred, and the pale-coloured thin ſeed ſhould be rejected. The Clover-ſeed ſhould be ſown after the Barley is harrowed in, otherwiſe it will be buried too deep; and after the ſeeds are ſown, the ground ſhould be rolled, which will preſs the ſeeds into the ground; but this ſhould be done in dry weather, for moiſture will often cauſe the ſeeds to burſt, and when the ground is wet, the ſeeds will ſtick to the roll. This is the method which is generally practiſed by moſt people in the ſowing of this ſeed with Corn, but it will be much better if ſown alone; for the Corn prevents the growth of the plants until it is cut and taken off the ground, ſo that one whole ſeaſon is loſt; and many times, if there be a great crop of Corn upon the ground, it ſpoils the Clover, ſo that it is hardly worth ſtanding; whereas, when it is ſown without any other ſeed, the plants will come up more equal, and come on much faſter than that which was ſown the ſpring before under Corn.

Therefore from many years trial I would adviſe the ſeeds to be ſown in auguſt, when there is a proſpect of rain ſoon after; for as the ground is at that ſeaſon warm, ſo the firſt ſhower of rain will bring up the plants, and theſe will have time enough to get ſtrength before the winter: and if, ſome time in october, when the ground is dry, the Clover is well rolled, it will preſs the ground cloſe to the roots, and cauſe the plants to ſend out more ſhoots; the ſame ſhould be repeated in march, which will be found very ſerviceable to the Clover. The reaſon of my preferring this ſeaſon for the ſowing of the ſeeds rather than the ſpring is, becauſe the ground is cold and wet in ſpring, and if much rain fall after the ſeeds are ſown, they will rot in the ground; and many times when the ſeed is ſown late in the ſpring, if the ſeaſon ſhould prove dry, the ſeeds will not grow, ſo that I have always found the other ſeaſon has been the beſt.

About the latter end of may this Graſs will be fit to cut, when there ſhould be great care taken in making it; for it will require a great deal more labour and time to dry than common Graſs, and will ſhrink into leſs compaſs; but if it be not too rank, it will make extraordinary rich food for cattle. The time for cutting it is, when it begins to flower; for if it ſtands much longer, the lower part of the ſtems and the under leaves will begin to dry, whereby it will make a leſs quantity of hay, and that not ſo well flavoured.

Some people cut three crops in one year of this Graſs, but the beſt way is to cut but one in the ſpring, and feed it the remaining part of the year, whereby the land will be enriched, and the plants will grow much ſtronger.

One acre of this plant will feed as many cattle as four or five acres of common Graſs; but great care ſhould be taken of the cattle when they are firſt put into it, leſt it burſt them: to prevent which, ſome turn them in for a few hours only at firſt, and ſo ſtint them as to quantity; and this by degrees, letting them at firſt be only one hour in the middle of the day, when there is no moiſture upon the Graſs, and ſo every day ſuffer them to remain a longer time, until they are fully ſeaſoned to it; but great care ſhould be had never to turn them into this food in wet weather; or if they have been for ſome time accuſtomed to this food, it will be proper to turn them out at night in wet weather, and let them have hay, which will prevent the ill conſequences of this food; but there are ſome who give ſtraw to their cattle while they are feeding upon this Graſs, to prevent the ill effects of it; which muſt not be given them in the field, becauſe they will not eat it where there is plenty of better food. There are others who ſow Rye-graſs amongſt their Clover, which they let grow together, in order to prevent the ill conſequences of the cattle feeding wholly on Clover; but this is not a commendable way, becauſe the Rye-graſs will greatly injure the Clover in its growth, and the ſeeds will ſcatter and fill the ground with bents.

Where the ſeeds are deſigned to be ſaved, the firſt crop in the ſpring ſhould be permitted to ſtand until the ſeeds are ripe, which may be known by the ſtalks and heads changing to a brown colour; then it ſhould be cut in a dry time, and when it is well dried, houſed until winter, when the ſeeds ſhould be threſhed out: if they are wanted for immediate ſowing, they muſt be well dried, otherwiſe they will not quit their huſks.

It is a common complaint that Clover ſeed requires great labour to threſh it; which is chiefly owing to the ſecond crop being left for ſeed, which ripens ſo late, that there is not heat enough to dry the huſks ſufficiently. This may be remedied by leaving the firſt crop for ſeed; and then the ground will be ready to plough and prepare for wheat.

When cattle are fed with Clover hay, it ſhould be put into racks, otherwiſe they tread a great quantity of it down with their feet. This ſeed is much better for any other cattle than milch cows; though when it is dry it is not near ſo injurious to them as when green.

The moſt approved method of ſowing red or broad Clover is on clean land, with a full crop of barley after turneps, at the rate of twelve pounds to an acre. The duration of it is very ſhort, except on freſh land; which points out the propriety of intermixing with it as great a variety of other crops as may be ſuitable. On land where it has been often repeated, it ſeldom will continue above two years, and very often not above one; and though manure will increaſe the crop, it will not prolong its ſtay. Clover evidently grows moſt kindly after turneps, and any ſoil that will bear them, is ſuitable for it. There is however a great quantity of Clover now grown on ſtrong clays, with good ſucceſs. A common way is, to mow it in june, and make it into hay. Two tons upon an acre may be reckoned a medium crop. It is particularly good for draft horſes and oxen. Sometimes it is mowed a ſecond time, late in auguſt; but the hay of this ſecond crop is leſs in quantity, and of an inferior quality to the former; unleſs dry fodder therefore be greatly wanted, it is better to feed it, inſtead of mowing a ſecond time.

When Clover is to be ſaved for ſeed, a common cuſtom is, to feed it down cloſe until the end of may; which early feed is a vaſt advantage for ewes, lambs, &c. as it comes in before the natural graſſes.

Theſe are the common advantages derived from Clover; but a greater benefit may be obtained by cutting it green, as often as it attains a ſufficient growth, and ſoiling horſes and cattle with it, in racks and cribs. In this manner it will ſupport more than twice the ſtock it would do if fed off the ground; beſides the additional quantity of manure, that will be made in the ſtables and yards, if they are kept littered with ſtraw, fern, &c. which increaſe of manure will fully compenſate the farmer for his expenſe in cutting and bringing the Clover into the yards. The quick growth of Clover after mowing ſhades the ground, and prevents the ſun from exhaling the moiſture of the land, ſo much as it would if fed bare; conſequently it continues to ſpring with more vigour; and the moment one crop is off, another begins to ſhoot up. Whereas when cattle feed it, they frequently deſtroy as much as they eat; and beſides, break the necks of the roots with their feet, which prevents the Clover from ſpringing ſo freely as it does after a clean cut by the ſcythe. In hot weather, which is the common ſeaſon for feeding Clover, the flies are generally ſo troubleſome to the cattle, that they are continually running from hedge to hedge, to bruſh them off, by which it is inconceivable what injury they do to the crop. But when they are fed in ſtables and yards, they are more in the ſhade, they thrive better, and conſume the whole of what is given them without waſte.

In the ſixth volume of the Tranſactions of the Linnean Society of London there is a full account by Mr. Markwick, Mr. Marſham, and M. C. G. Lehmann of Gottingen, three celebrated entomologiſts, of an Inſect, which is very deſtructive occaſionally to the ſeed of the common purple or honey-ſuckle Clover. It appears to be the *Curculio Trifolii* of Linneus; and is deſcribed by Mr. Marſham as having a black body, with an extended beak a little longer than the thorax, which has ſmall dots on it; the elytra or wing-covers are ſtriated; the antennæ pitchy; the legs ruſt-coloured, but the feet always black: the thighs are alſo ſometimes black. The abdomen is white. The length of the body is a line and half. It is figured in *t.* 5. at *p.* 94. at the bottom of the plate.

The damage done by this ſmall inſect, which we may call the *Clover Weevil*, is ſometimes conſiderable. Mr. Markwick informs us, that in 1798, four acres and a half produced him ſixteen buſhels three quarters of Clover ſeed, which ſold for 41l. 17s. 6d.: and in the year 1800, the ſame quantity of ground produced only ſeven buſhels and a half, worth at the ſame price 18l. 15s.—This deficiency was probably occaſioned by the depredations of this Inſect, and the ſeed was alſo of an inferior quality.

Theſe Weevils come out early in ſpring in warm paſtures, and fly about till the heads of Clover break out, when the females depoſit their eggs on them. Hatched, between the calyxes, the maggot penetrates with its head into the rudiments of the firſt ſeed, as yet in a liquid ſtate, and then proceeds to another more advanced and ſuitable to its increaſed ſtrength. Having conſumed three or four of them, it remains in the place of the laſt, where it is ſufficiently ſheltered, and changes into its pupa or chryſalis ſtate; and after a few days comes forth in its perfect ſtate. Having taken a ſhort meal, it then ſlowly conceals itſelf in the ſmall holes of fences, or in the bark of trees, where it repoſes during the winter. Happily the wren, red-breaſt, and other ſmall birds deſtroy great numbers; but the fecundity of the remainder is prodigious.

There is a variety of Clover called *Cow-graſs*, which has been cultivated in ſome parts of Hampſhire with great ſucceſs. The ground reliſhes it extremely well, and it is by many preferred to common Clover. It grows more floridly, and thrives better upon poor land. At firſt they are not eaſily diſtinguiſhed; but on a cloſe inſpection, the *cow-graſs* will be found of a darker green, and more pointed at the ends of the leaves; the ſtalk is of a cloſer texture, and not ſo porous as the common Clover [d].

This ſeems to be that variety of Trifolium pratenſe, which is figured in the Flora Ruſtica, under the name of Cow-graſs.

Mr. Arthur Young ſays, that it is raiſed for ſeed in the weald of Suſſex; that there is a market for it at Heffel; and that it is ſent to London: he wiſhes the cultivators of it, would take care that they have Cow-graſs, which is the Tr. alpeſtre, (our Tr. medium,) a plant quite different from the Cow-graſs of the ſhops: its roots run laterally under ground, like thoſe of couch or quich [e].

He alſo informs us that Mr. Roper, the Duke of Grafton's ſteward, in the ſpring of 1789 ſowed part of a field with red Clover, and the reſt of it with Cow-graſs, brought from Ayleſbury in Buckinghamſhire, with barley after turneps. Both were mown for hay in 1790, the common Clover giving the greateſt produce, and rather the moſt after-graſs. The following year both were fed, and the cow-graſs yielded vaſtly more than the Clover, and of a better quality. They are apparently of a decidedly different habit and quality: the cow-graſs ſpreads more on the ground; thicker; the ſtalk is ſolid, not pipy, and it does not run equally to bloſſom. Mr. Young remarks however, that to all common appearance they are the ſame, for he does not put much faith in a doubtful appearance of ſolidity in the ſtalk [f].

[d] Kent's hints, 41. [e] Young's annals, 11. 246. [f] Idem, 16. 496.

The former of theſe may be our Tr. medium, which was taken by Hudſon for the alpeſtre. But the alpeſtre is quite different, and not a native of England. The latter cannot be the medium, if it is at all like the pratenſe, but is probably a wild variety of the latter.

A farmer at Burcleer, near Newberry, ſays, that Cow-graſs is found to ſucceed on land where Clover has been too often repeated, and that it grows very plentifully on any wet ſpewy ground, even in moiſt ſeaſons, generally producing three tons of hay on an acre at one cutting, but not any ſecond crop in the ſame year; it lodges very much, and is troubleſome to mow: the hay is ſaid to be preferred by horſes to clover hay [g]. We do not know what ſpecies or variety this may be. It ſeems as if Cow-graſs was not the ſame thing in different counties. The Hampſhire ſort is figured in Flora Ruſtica; in the ſame work may be found the meadow Clover in its wild ſtate, under the falſe name of *Tr. medium*, and the true *Tr. medium* under the name of *flexuoſum*. The *medium* is alſo figured in Engliſh Botany. With the aſſiſtance of theſe figures, and the ample deſcriptions given in this work, the *pratenſe*, *medium* and *alpeſtre* cannot well be confounded.]

27. Mr. Miller ſays that in ſome counties this is ſown after the ſame manner as the common red Clover, eſpecially on chalky ground, where it will thrive, and produce a better crop than Clover.

[But Mr. Miller ſeems to have miſtaken this ſpecies, for he ſays that the flowers are of a pale copper colour; and that it is known by the name of Trefoil.

A new ſort of Clover has been found and cultivated near Bawtry in Yorkſhire, which is ſuppoſed to be the *ochroleucum*; but if the deſcription be exact it cannot be that ſpecies, for it is ſaid that the nob (flowering head) has white cups tipped with pink [h]: now that is ſometimes the caſe with the *repens* or white Dutch Clover; but the *ochroleucum* has the florets of a pale brimſtone colour. Nor does the latter, ſo far as we can judge from it in its wild ſtate, promiſe to rival broad Clover in any degree except in its permanency.]

49, 50. Theſe grow naturally among graſs in moſt of the upland paſtures in this country; and the ſeeds of the former are frequently ſold in the ſhops by the name of Hop-Clover, and are by many mixed with other ſorts of clover and graſs-ſeeds, for laying down ground to paſture. The latter is a much ſmaller plant, and has trailing ſtalks. The heads of flowers are ſmaller, and of a deeper yellow colour. Theſe not being abiding plants, are by no means proper to be ſown where the ground is deſigned to continue in paſture; but where one or two crops only are taken, and the land is ploughed again for corn, it may do well enough when it is mixed with other ſeeds, though the cattle are not very fond of it green, unleſs when it is very young. The large ſort is the moſt profitable, but this is rarely to be had without a mixture of the ſmall kind, and alſo of the ſmaller Melilot, which is commonly called Noneſuch, or ſometimes Black Seeds, for thoſe who ſave the ſeeds for ſale, are ſeldom curious enough to diſtinguiſh the ſorts; but in lawns, where the beauty of the verdure is conſidered, there muſt not be any of theſe ſeeds ſown, becauſe their yellow heads of flowers are very unſightly among the graſs; and if it is in gardens where the graſs is conſtantly mowed, the flowers of theſe plants will come out near the root in ſuch cluſters, as to occaſion large, unſightly, yellow patches; and as the heads decay they turn brown, and have a very diſagreeable appearance. [See *Medicago lupulina*.

Hartlib, in his Compleat Huſbandman, 1659, mentions a place in Kent, which is a white chalky down, ſometimes ſown with corn a year or two, and then reſting as long or longer; when it is laid down, maintaining many great ſheep and very luſty, ſo that they are even fit for the butcher; and yet there doth not ſcarce appear any thing that they can eat, which hath

[g] Young's annals, 17. 413. [h] Idem, 24. 529 to 535.

Digitized by Google

caused divers to wonder, as if they had lived on chalk-stones: but I, says Hartlib, thoroughly viewing the ground, perceived that it naturally produceth a small Trefoil, which it seemeth is very sweet and pleasant; it is commonly called *Trifolium luteum* or *lupulinum*, that is *yellow* or *Hop-Trefoil*: and I am persuaded, if that the seed of this Trefoil were preserved, and sown with oats, when they intend to lay it down, it would very much advance the pasture of that place. Therefore I desire all ingenious men, seriously to consider the nature of the Trefoils, which are the sweetest of grasses, and to observe on what grounds they naturally grow, and also the nature of other grasses naturally growing in this isle, some on watry places, some on dry, some on clay, others on sand, chalk, &c. some on fruitful places, others in barren; by the which means I suppose a solid foundation might be laid for advancing the pasture lands of all sorts, through this island[i].]

As to the other species, which are mostly preserved in botanic gardens, they are easily propagated by seeds, sown in an open bed of ground, either in autumn or spring. The plants which come up in autumn will grow much larger, and flower earlier in the summer; from these therefore good seeds may be generally obtained, whereas the others sometimes miscarry. When the plants come up, they require no other care than to keep them clean from weeds, and to thin them where they are too close.

DESCRIPTIONS, &c.

1. Root fibrous, tufted, perennial. Leaves radical, sheathing, bifarious, linear, channelled, somewhat more slender and less fleshy than in the *maritimum*, but like them semicylindrical, with a membranous, sheathing, intrafoliaceous stipule. Scape solitary, erect, simple, a foot high, longer than the leaves, bearing a long, thick-set, but slender spike of numerous flowers, smaller than in the *maritimum*. The most certain and striking distinction between them is, that the fruit of this is much more long and slender, having only three cells and three valves instead of six. These valves separating from the base, look like a three-barbed arrow-head; whence the name. Seeds linear[k].

Gærtner describes the fruit as narrow, elliptic, tripartile and tricapsular. Capsules acuminate downwards, three-sided, valveless. Common receptacle three-sided, but augmented moreover by three wings, as it were so many intercalary partitions, which perhaps may be abortive capsules stifled by the neighbouring ones.

Native of Europe, Siberia and Barbary, in wet boggy meadows, flowering in july. All cattle will eat it, and Dr. Withering says cows are extremely fond of it[l].

2. Root bulbous, covered with bristles heaped into a tufted bundle. Scape scarcely half a foot high, channelled a little on one side. Leaves radical, filiform, and slightly channelled on one side like the scape.

The flowers and whole plant very much resemble the preceding species, but the flowers and fruit are smaller. Styles three, protracted and spreading; whereas in T. palustre they are erect and obsolete.—Native of the Cape of Good Hope[m].

3. Scape scarcely longer than the leaves, inclining at the base, terminating in a dense spike of greenish-purple flowers, on short flower-stalks. Leaves wider

and

Digitized by Google

and more fleshy than in the palustre, with which it agrees in habit. The six anthers are almost sessile, and very large before they burst. Germ with six furrows, changing to an ovate capsule, which is shorter than that of the first, and has six cells; whereas T. palustre has but three [a].

Gærtner describes the fruit as composed of six superior capsules, united into one ovate-globular, striated fruit, three-sided, gibbous on one side and scored with a furrow; acute-angled on the other and straight, coriaceous, one-celled and valveless. Common receptacle filiform, three-sided, in the axis of the fruit: proper, a very short umbilical chord leading from the top of the cell to the upper part of the seed. In each capsule one seed, which is long, drawn to a point at each end, three-sided, of a pale greenish colour.

Native of most parts of Europe, and of Siberia, in salt marshes, and in the ooze of large rivers, where the tide flows; flowering throughout the summer. All domestic cattle being very fond of this plant, it may deserve the notice of such as possess salt-marshes [b].]

TRIGONELLA. (*Dimin. from* trigona (corolla); *so named from its three-cornered corolla.*)

Lin. gen. n. 898. *Reich. n.* 970. *Schreb. n.* 1213. *Gærtn. t.* 152. *Juss.* 356. Fœnum-græcum. *Tournef. t.* 270.

Class. 17. 4. Diadelphia Decandria.

Nat. order of *Papilionaceæ* or *Leguminosæ*.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, bell-shaped, half-five-cleft: *toothlets* awl-shaped, nearly equal.

COR. papilionaceous, as it were three-petalled?

Banner subovate, obtuse, reflex-spreading.

Wings two, ovate-oblong, outwardly reflex-spreading, so that the banner with the wings constitutes as it were a regular three-petalled corolla.

Keel very short, obtuse occupying the navel of the flower.

STAM. *Filaments* diadelphous (simple and nine-cleft) short, rising. *Anthers* simple.

PIST. *Germ* ovate-oblong. *Style* simple, rising. *Stigma* simple.

PER. *Legume* ovate-oblong, compressed, covered.

SEEDS many, roundish.

OBS. *From the form of the corolla only this becomes a distinct genus.*

ESSENTIAL CHARACTER.

Banner and *wings* nearly equal, spreading, in form of a three-petalled corolla.

12. Trigonella pinnatifida.
Cavan. ic. biſp. 1. 26. *n.* 40. *t.* 38.
Stem proſtrate four-cornered, legumes linear compreſſed erect ſeſſile.]

DESCRIPTIONS, *&c.*

1. This is a biennial plant; the roots decaying ſoon after the ſeeds are ripe. Stalks very ſlender, trailing, extending a foot and half in length, and dividing into ſeveral branches. Leaflets wedge-ſhaped, indented at the point and ſerrate, narrower than in the ſecond and fourth: [according to Linneus, they are lanceolate, very blunt, acutely ſerrate above, and toothed; and the ſtipules are quite entire.] The flowers are produced in cluſters upon ſlender axillary peduncles; they are ſmall, and of a bright yellow colour. The pods are narrow (linear) and erect. Linneus ſays pendulous. They contain three or four ſeeds.—Native of Siberia.

[It was cultivated in 1759, by Mr. Miller, who received the ſeeds from Dr. Amman, profeſſor of Botany at Peterſburgh. It flowers in june and july [p].]

2. Root biennial, like the preceding. Stalks trailing, extending a foot in length, and ſending out many ſide branches. Leaflets roundiſh, ſerrate: [according to Linneus, ſubovate and acutely ſerrate longitudinally. Stipules commonly toothed.] Flowers in cluſters, peduncled, axillary; they are ſmall, and of a yellowiſh white colour. Pods oval, compreſſed, containing two ſeeds. It flowers in june, and the ſeeds ripen in ſeptember. Native of Siberia, whence the ſeeds were ſent with the other by Amman, [to Mr. Miller, who cultivated this ſpecies in 1759 [q].

3. Annual. Leaflets, eſpecially the younger ones having lateral, ſnow-white ſtreaks. Common peduncle longer than the leaves, erect, awnleſs at the top, with five or ſix terminating flowers, not in a raceme, ſeſſile, yellow. Legumes umbelled, almoſt erect, like the fingers of the hand ſtretched out, linear, ſeſſile, five or ſix, a little bowing inwards. Native of Abyſſinia [r].]

4. This is an annual plant, the roots decaying ſoon after the ſeeds are ripe. Stalks trailing, extending a foot and half in length, and ſending out ſeveral ſide branches. Leaves ſmall; the leaflets wedge-ſhaped and ſerrate at their points. Flowers in axillary cluſters; ſmall, of a pale yellow colour, and ſitting very cloſe to the ſtalks. Pods ſhort and hooked, ſeſſile and ſpreading out every way. It flowers in july, and the ſeeds ripen in autumn. [Cultivated in 1759, by Mr. Miller [s].

5. Annual. Stems decumbent, aſcending. Leaflets obovate, wedge-ſhaped, toothed, veined, pubeſcent. Peduncle longer than the leaf, terminated by a ſpine. Flowers in racemes, having the banner ſhorter by half than the wings or keel. Legumes as far as ten, filiform, hooked, hanging down, aſcending at the tip towards the calyx. Native of Egypt, where it was found by Haſſelquiſt [t].

Cultivated here in 1640, as appears from Parkinſon [u], in whoſe time it was ſuppoſed to be a native of the Eaſt Indies.]

6. The ſtalks of this are ſlender, and riſe a foot high, ſending out ſeveral ſlender branches. Leaflets wedge-ſhaped, ſerrate at the ends, where they are indented, ſtanding upon ſlender foot-ſtalks. Flowers in cluſters from the ſides of the branches upon ſhort peduncles, which ſtand erect, and are armed with ſhort ſpines: they are ſmall, and of a pale colour. Pods narrow, parallel, and erect. This is an annual plant, which flowers in july; the ſeeds ripen at the end of auguſt, and the plant decays ſoon after.

[Stipules toothed. The peduncle becomes a rigid ſpine, at the baſe of which are often five veined ſmooth legumes [x].—Theſe are linear-oblong, ſickle-ſhaped, roundiſh or very ſlightly compreſſed, with tranſverſe raiſed nerves. Seeds eight to twelve, ovate-oblong with a beak, yellow [y].

Native of the iſland of Candia. Cultivated in 1739 by Mr. Miller [z].

7. Annual. Stem upright. Stipules ſimple, ſomewhat toothed. Peduncle four-cornered, longer than the leaf, ſoftly-ſpiny at the end, under which are from ten to twelve ſickle-ſhaped legumes, ſhorter than the peduncle. Calyxes before they unfold very obſcure. Flowers extremely ſweet-ſcented. Native of the South of Europe [a]. Cultivated in 1597 by Gerarde. It flowers in june and july [b].

8. Annual. Stems proſtrate, growing cloſe to the ground. Peduncle very ſhort, ſoftly mucronate, not longer than the leaf. Legumes ten to twelve, declining [c].

Stems many in the ſame tuft, pubeſcent. Leaves fan-ſhaped, pubeſcent with a very ſhort down, toothletted, nerved beneath, with the middle leaflet petioled. Stipules narrow, acute. Flowers very ſmall, yellow, glomerate, ſeſſile along the ſtem. Legumes compreſſed, ſickle-ſhaped, acute, ſtriated tranſverſely [d].

Tr. ſtellata of Forſkahl is a mere variety, and differs from Linneus's *monſpeliaca* only in having the leaves not rounded at the end but retuſe [e].

Native of France, Italy and Algiers.—Introduced in 1771, by Monſ. Richard. It flowers in june and july [f].

9. This reſembles Medicago polymorpha laciniata. Stems filiform, even. Leaflets even, retuſe, finely toothed. Stipules jagged-toothed. Peduncles axillary, ſcarcely the length of the leaves, terminated by a ſoft ſpinule, bearing a few yellow flowers in a ſort of umbel. Legumes almoſt like thoſe of Melilot, oval, ſharp at both ends, twice as long as the calyx. Native of Egypt [g].]

10. Common Fenugreek is an annual plant, which riſes with a hollow, branching, herbaceous ſtalk. Leaflets oblong, oval, indented on their edges, on broad furrowed foot-ſtalks. The flowers come out ſingly at each joint from the axils; they are white, and ſit very cloſe to the ſtalk. Pods long, compreſſed, ſhaped ſomewhat like a broad-ſword, ending in long points, and having a broad membrane on one edge: they are filled with ſquare yellow ſeeds, indented on one ſide like a kidney. The whole plant has a very ſtrong odour.

[It is ſmooth. The ſtem is ſimple or ſparingly branched and ſtriated. Leaves petioled: leaflets obovate or elliptic, toothletted above, the middle one of the three petioled. Legumes ſeſſile, axillary, compreſſed, bowed, the upper margin thinner, having a long awl-ſhaped point [h]:—they are very long, filiform-acuminate, narrow, ſomewhat compreſſed and ſickle-ſhaped, opening by the convex margin. Seeds ſometimes as many as eighteen, rhomboid, gibbous, beaked with a depreſſed line, yellow or ſaffron-coloured [i].

Native of France, the county of Nice, Spain, Germany and Barbary.—Cultivated in 1597, according to Gerarde [k], who ſays, we ſow a ſmall quantity in our gardens.

The ſeeds are brought to us from the South of France and Germany, where they are annually ſown for exportation.

They have a ſtrong diſagreeable ſmell, and an unctuous farinaceous taſte, accompanied with a ſlight bitteriſhneſs. An ounce renders a pint of water thick and ſlimy. To rectified ſpirit they give out the whole of their diſtinguiſhing ſmell and taſte, and afterwards to water a ſtrong flavourleſs mucilage.

Theſe ſeeds are never given internally, their principal uſe being in cataplaſms and fomentations, for ſoftening, maturating, and diſcuſſing tumours; and in emollient glyſters. They were alſo an ingredient in the *oleum e mucilaginibus*; but this has no longer a place in the pharmacopœia [l]. They are uſed by grooms and farriers for horſes.

β. The wild plant differs, in having long-runners next the root, all preſſed cloſe to the ground, the ſtem only being upright; leaflets obovate, not ob-

tufely lanceolate; with the joints of the leaves purple. Legumes more hairy [m].

11. Procumbent, not much branched. Leaves petioled: leaflets almoft equal, fomewhat oblong, fmooth. Stipules ovate-lanceolate. Legumes one or two on the fame peduncle, fubfeffile in the axils, recurved, compreffed [n].—Native of the Eaft Indies.

12. Root annual, long, fibrous. Stems numerous, branched, red. Leaves diftant, fhorter than the common petiole, which is channelled: the lower feffile with the third petioled, pinnatifid-ferrate, retufe. Stipules jagged at the bafe, acute at the tip. Flowers axillary, feffile, from three to five. Corolla pale yellow. Legumes an inch long, erect and bowed a little; containing many feeds. Native of Spain, in the neighbourhood of Madrid.

It refembles Medicago polymorpha laciniata, of Linneus, and therefore Trigonella laciniata, but it differs from them entirely in the legumes [o].

The leaves in all the fpecies are ternate.]

PROPAGATION AND CULTURE.

1 to 9. Thefe are hardy annuals. Sow the feeds where the plants are deftigned to ftand, for they will not bear tranfplanting. If they are fown in autumn, in the way directed for the common fort, the plants will come earlier to flower, and good feeds may be obtained with more certainty than from fpring plants. All the culture they require, is to thin them where they ftand too clofe, and to keep them clean from weeds.

10. The ground in which this plant thrives beft, is a light hazel loam, not enriched with dung; this fhould be made clean from the roots of weeds, and well ploughed twice, and harrowed fine before the feeds are fown. The beft time to fow the feeds is the latter end of auguft or beginning of feptember; thefe fhould be fown in fhallow drills like Peas. The rows fhould be two feet afunder, and the feeds muft be fcattered one inch diftant from each other in the drills; for if the plants are too clofe together in the fpring, they may be eafily thinned with the hoe when the ground is cleaned. If the feeds are fown at the before-mentioned time, the plants will appear in three weeks or a month after; and if the weeds appear at the fame time, the ground fhould be hoed over as foon as poffible in dry weather, to deftroy the weeds; and when the plants are grown an inch high, the earth fhould be drawn up to their ftems in the fame manner as is practifed for Peas. This will fecure their ftems from being injured by fharp cutting winds; and if a ridge of earth is drawn up on the north or eaft fide of each row, it will protect the plants from the pinching winds which blow from both thofe quarters; for although this plant will not be in any danger from the froft in the ordinary winters, yet in very fevere frofts it is fometimes killed; but as this plant will live in any fituation, where Peas ftand through the winter, there will be no greater hazard of the one crop than the other.

In the fpring of the year the ground muft be hoed again in dry weather to kill the weeds, and the plants fhould be again earthed up in the like manner as Peas, with whofe culture this plant will thrive; but there muft be great care taken to keep the ground as clean from weeds as poffible, for if they are permitted to grow, they will foon advance above the plants, and greatly weaken them; and when their pods begin to form, they cannot be too much expofed to the fun and air, whereby they will be lefs liable to fuffer from moifture.

When the feeds are fown in autumn, the plants will grow much ftronger, and have many more fide branches than thofe which come up in the fpring, fo will produce a much greater crop of feeds, and thefe will produce their flowers five or fix weeks earlier, and have a better feafon to ripen; but in order to have them better ripened, the top of the plants fhould be cut off with garden fhears about the middle of june, by which time the pods will be formed on the lower part of the ftalks, which will be greatly forwarded by topping the ftalks in the fame way as is commonly practifed for garden Beans; for where the plants are fuffered to extend in length, the lower pods often mifcarry, or are lefs nourifhed, and thofe on the top of the ftalks are late before they ripen; fo where the topping of the plants is omitted, the pods at bottom will open and caft out their feeds, before thofe above will be ripe; therefore to preferve the firft and cut off the other, will be found the beft method; for by fo doing, the pods will ripen equally, and much earlier in the feafon.

If the fummer proves warm, the feeds will ripen in auguft, and the plants fhould then be cut off, and laid to dry for five or fix days, in which time they fhould be turned two or three times, that the pods may dry equally; then the feeds may be either threfhed out in the field, or the haulm may be houfed in a barn, to be threfhed at a more convenient time.

Fenugreek has not been cultivated in any quantity for ufe in England, becaufe it is an uncertain crop, occafioned by the inconftancy of our weather; the plants, in cold feafons being frequently killed, before the feeds ripen; or if they live long enough to have the feeds perfected, the pods change of a dirty colour, and the feeds turn black and unfightly, when much rain falls in the autumn.

[Dr. Woodville however affirms, that in dry feafons it ripens the feeds here very well, and judging by his own experience, he thinks it might be cultivated to great advantage in this country.

TRIGONIA. (*So named from the form of the fruit.*)

Lin. gen. Schreb. n. 1178. *Aubl. t.* 149. 150. *Juff.* 253.

Claff. 17. 4. Diadelphia Decandria.

Nat. order of *Malpighiæ* Juff.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, turbinate: *border* five-cleft, the two upper fegments more deeply feparated, erect, diverging.

COR. papilionaceous; five-petalled.
Banner erect, flat, clawed.
Wings reflexed, longer, narrower.
Keel two-petalled, converging.

STAM. *Filaments* ten, connected into a fheath, diftinct at top, fome (3, 5, 7.) often barren. *Anthers* oblong.

PIST. *Germ* ovate, fmall. *Style* fhort, afcending. *Stigma* headed, flat, girt with a membranaceous margin.

PER. *Capfule* oblong, three-cornered, three-grooved, acute, one-celled, three-valved: *valves* boat-fhaped, doubled; outer coriaceous, inner membranaceous woolly within.

SEEDS very many, roundifh, involved in long wool, faftened to three threads uniting the valves.

OBS. *Are the feeds faftened rather to one future only? It may be doubted whether this genus be rightly referred to this place?* S.

ESSENTIAL CHARACTER.

Cal. five-parted. *Pet.* five, unequal, uppermoft foveolate at the bafe within. *Nect.* two fcales at the bafe of the germ. *Filam.* fome barren. *Capf.* leguminofe, three-cornered, three-celled, three-valved.

SPECIES.

1. Trigonia villofa.
Aubl. guian. 188. *t.* 149. *Vahl ecl.* 2. 53.
Leaves obovate beneath tomentofe hoary.

2. Trigonia lævis.
Aubl. guian. 190. *t.* 150.
Leaves oblong on both fides fmooth fhining.

DESCRIPTIONS, &c.

1. Branches round, fmooth below, villofe above: branchlets hoary-tomentofe. Leaves on the younger branchlets petioled, oppofite, two or three inches long, ovate, attenuated towards the bafe, mucronate from the rib running out a little beyond the leaf, reflexed a little at the edge, fmooth above, villofe on the rib only which is yellowifh, marked with lines along the nerves; beneath tomentofe, hoary, netted-veined, both nerves and veins raifed and villofe with yellowifh hairs. Racemes from the laft axils quite fimple, terminating, compound: branches oppofite, fpreading very much, decreafing upwards. Pedicels oppofite

[m] Linn. fpec. [n] Linn. zeyl. [o] Cavanilles.

Digitized by Google

oppoſite or alternate, ſpreading very much, with a yellowiſh down on them like the peduncles. At the baſe of each pedicel are two briſtle-ſhaped bractes. Calyx five-parted: ſegments ovate, acute, without tomentoſe and hoary, within ſmooth, one of them more interior and a little wider than the reſt, on the outſide ſnow-white with a raiſed green line on the back. Upper petal wider than the reſt, outwardly gibbous at the baſe, inwardly oppoſite to the bump an excavation with villoſe margins: the two lateral ones a little longer, linear-wedge-ſhaped, ſomewhat ſickle-ſhaped, the two lower oblong, gibbous in the middle of the inner ſide towards the edge. Nectary compoſed of two ſcales, which are ſtiffiſh, ſmall, ruſeſcent, ſmooth, a little connected at the baſe by one edge. Filaments ſtraight by the two lower petals, on one ſide of the germ, at firſt united, but afterwards dividing into two bodies, having five filaments in each, three of which are equal and have anthers, the other two are ſmaller and barren. Anthers ſmall, roundiſh. Germ villoſe, hoary. As the filaments do not ſeparate but as the germ increaſes, it might perhaps be more proper to inſert this genus in the claſs Monadelphia. Native of Cayenne.

2. Branches below ſmooth, round, having very numerous raiſed dots ſcattered over them; above flatted and ſomewhat four-cornered, alſo inclined to be villoſe. Leaves petioled, oppoſite, two or three inches long, oblong, ſharpiſh, quite entire, ſmooth on both ſides except the rib, veined, ſhining, paler beneath. Petioles a quarter of an inch in length, ſomewhat villoſe. Stipules none. Racemes from the upper axils and ends of the branches, erect, ſtiff; the terminating ones three inches long, with a few oppoſite branches at the baſe; the axillary ones quite ſimple, an inch or a little more in length. Flowers ſmaller by half than in the preceding, for the moſt part ſolitary, but ſometimes two together, on ſhort pedicels, hoary on the outſide. At the baſe of the pedicels there is a minute bracte. Leaflets of the calyx lanceolate, ſubcinereous. Nectary as in the preceding. Native of Guiana [p].

TRIGŌNIS. See *Cupania*.

TRIGOSANTHES. See *Feuillea*.

TRIGUERA. (*So named by Cavanilles, from a Spaniſh botaniſt.*)

Lin. gen. Schreb. n. 282. *Cavan. diſſ.* 2. *t.* A. *Juſſ.* 125.

Claſſ. 5. 1. Pentandria Monogynia.

Nat. order of *Luridæ*. *Solaneæ* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, half-five-cleft, permanent: *ſegments* unequal, acute.

COR. one-petalled, bell-ſhaped. *Tube* very ſhort. *Border* ventricoſe, plaited, five-cleft, longer than the calyx; the two upper ſegments reflexed.

Nectary membranaceous, ſhort, five-toothed, ſurrounding the germ.

STAM. *Filaments* five, very ſhort, inſerted outwardly into the teeth of the nectary. *Anthers* ſagittate, converging.

PIST. *Germ* roundiſh, two-grooved. *Style* filiform, ſtraight, a little longer than the ſtamens. *Stigma* obtuſe.

PER. a dry *Berry*, ſubglobular, grooved, four-celled.

SEEDS two in each cell, roundiſh, compreſſed, rugged: one above the other.

OBS. *The fruit is ſometimes two-celled, according to Cavanilles.*

ESSENTIAL CHARACTER.

Cor. bell-ſhaped, with an unequal border. *Nect.* ſhort, five-toothed, ſurrounding the germ. *Filam.* inſerted into the nectary. *Berry* four-celled, with two ſeeds in each cell.

SPECIES.

1. Triguera ambroſiaca.

Lin. ſpec. ed. Willd. 1. 839. *Cavan. diſſ.* 2. *app.* 2. *t.* A.

Stem grooved and winged, upper leaves obovate toothed pubeſcent.

Flower feffile erect.

DESCRIPTIONS, *&c.*

1. [Root perennial, tuberous. Stem erect, a foot high, fimple, round, flightly ftriated, fmooth. Leaves three together, terminating, on fhort foot-ftalks, fpreading, rhomboidal, pointed, entire, veiny, fmooth, paler beneath. Flower folitary, among the leaves, without bractes. Flower-ftalk round, a little waved, fmooth. Calyx-leaves ovate-oblong, acute, nerved, fmooth, reflexed. Petals the length and figure of the calyx, whitifh marked with blueifh lines, reflexed. Stamens half as long as the petals: filaments very fhort, equal, quadranglar, ftraight: anthers vertical, two-celled, purple. Germ ovate, pale yellowifh white, with fix membranous prominent angles: ftigmas three, feffile, recurved, pale purple[t].]

According to Mr. Miller, the ftalk rifes only five or fix inches high; the leaves are two inches long, and an inch and half broad, and of a deep green colour; the calyx is green, and the petals whitifh green on the outfide, but purple within. The flowers appear in april, and the berries ripen in june.

It grows naturally in the woods in many parts of North America; Mr. Miller had it from Philadelphia, by Dr. Benfel: [and cultivated it in 1759[t].

Kalm found it in Canada, and Mr. Archibald Menzies, in Nova Scotia[u]; Colden in New York, and Cateſby in Carolina.

Cateſby's figure is fo fhapelefs, and fo erroneoufly coloured, that I could never have believed it, fays Dr. Smith, to have been intended for this plant, had I not examined his original fpecimen in the Britifh Mufeum.—Dr. Smith's elegant figure was taken from a plant cultivated in the garden of Robert Barclay, Efq. at Clapham.

Of the qualities of this genus we know little. They probably agree with thofe of Paris quadrifolia[x].]

2. This has a taller ftalk. The three leaves are placed at a diftance from the flower, which ftands upon a long foot-ftalk, and is erect: the petals are purple, larger, and end with fharper points.

[Native of Virginia, Canada, and other parts of North America. Said to be found in the woods of Brafil, by a French apothecary, who fent it to Burfer[y].

Cultivated in 1699 by Bobart, who had it from Virginia by Baniſter[z]. It is the moft rare with us of the three fpecies; and is in the collection at Kew, though not inferted in the catalogue.

Cornutus's figure is good, and is copied in th Oxford hiftory. Its height is about nine inches, and it flowers in may[a].]

3. Stalk purple. The three leaves grow at the top like the firft; but they are much longer, and end in acute points. The petals are long, narrow, and ftand erect: [they are of a dark browniſh red, nearly the fame colour as the Carolina All-fpice. The calyx-leaves are ftreaked with red. The leaves are mottled.

It grows in fhady thickets in Carolina and Virginia. Mr. Curtis had the plant from which his beautiful figure was taken, from Mr. Robert Squibb, gardener, of Charleftown in South Carolina.]

PROPAGATION AND CULTURE.

Thefe plants are propagated by feeds, which fhould be fown upon a fhady border foon after they are ripe, and then the young plants will come up the next fpring; but if the feeds are fown in the fpring, they will remain in the ground a year. When the plants come up, keep them clean, and in autumn, after their leaves decay, tranfplant the roots to a moift fhady place, where they are to remain.

[The three fpecies grow in fhady fituations and a light foil, and require the fame treatment as Dodecatheon, and round-leaved Cyclamen. They continue to be rare plants in this country, becaufe they require much attention in their culture, admit of little increafe from their roots, and the procefs of raifing them from feeds is tedious. The *feffile* is the moft common, and the *erectum* is the moft rare. They are all hardy perennial plants, and flower in fpring[b].

TRILOPUS. See *Hamamelis.*

TRINITATIS HERBA. See *Viola tricolor.*

TRIONUM. See *Hibifcus.*

TRIOPTERIS. (*From* τρεις *and* πτερον, *triplex ala, three-winged. The fruit having three membranes.*)

Tetrapteris

Digitized by Google

Tetrapteris mucronata. *Cavan. diſſ.* 9. 434. *t.* 262. *f.* 2.

Leaves oblong acuminate ſmooth, umbels panicled terminating, fruits four-winged, wings in pairs the lower ones ſhorter.

7. Triopteris buxifolia.
Lin. ſpec. ed. Willd. 2. 745.
Tetrapteris buxifolia. *Cavan. diſſ.* 9. 434. *t.* 262. *f.* 1.

Leaves oblong bluntiſh ſmooth, umbel terminating, fruits four-winged, wings almoſt equal.

8. Triopteris citrifolia.
Lin. ſpec. ed. Willd. 2. 745. *Swartz prodr.* 75. *deſcr.* 2. 857.
Tetrapteris inæqualis. *Cavan. diſſ.* 9. 433. *t.* 260.
Acer ſcandens tricoccos folio citri, flore luteo majore. *Plum. ic.* 9. *t.* 16.

Leaves ovate-oblong acute ſmooth, umbels axillary peduncled, fruits four-winged; wings in pairs, the lower ones ſhorter.

DESCRIPTIONS, *&c.*

1. This is a climbing ſhrub, with a twining ſtem, and ſpreading, diverging, looſe, round ſmooth branches. Leaves oppoſite, lanceolate-ovate or ovate with a long point, quite entire, beautifully veined, dark green; on ſhortiſh petioles. Racemes terminating, ſeldom axillary, ſpreading like panicles; branches oppoſite, ſubdivided, looſe; flowers on ſhort peduncles, ſcattered, pale blue, ſmall [c].

Linneus ſays it has the fruit of Baniſteria, conſiſting of three diſtinct capſules, with three wings, containing each one ſeed. Gærtner calls them *Samaræ*, ſubglobular, coriaceous, three-winged at the back: the middle wing narrow, linear-oblong, three times ſhorter than the ſide ones, which are membranaceous, confluent below into a ſimple oblong ligule or ſtrap, but divaricating above and ovate-oblong. Seeds ſubglobular, browniſh red.

Native of Jamaica and Hiſpaniola.

2. This is a large twining ſhrub. Leaves oppoſite, ovate, acute, waved and ſometimes a little ſcolloped, entire, from three to four inches long, and two broad. Petiole channelled, downy, three-fourths of an inch long. Panicles terminating and axillary, croſs-armed, ſmall, delicate; or the whole extremity of the branchlets may be called one beautiful large leafy panicle. Bractes ſmall, ruſt-coloured. Flowers very numerous, white: petals oblong, concave, without claws. Stigmas headed, entire: ſometimes the three ſtyles adhere as if one. Seeds three, linear-oblong, united at the ſeeds themſelves, each ſurrounded by a very large membranous wing [d].

Native of the Eaſt Indies, in mountain foreſts.

3. Stem ſhrubby, branched: branches oppoſite, jointed, ſmooth, as is the whole plant. Leaves quite entire, hardiſh, on petioles four times ſhorter than the leaf, and having two glands near it. Stipules on each ſide two, like little teeth. Calyx very ſmall, with ovate ſegments, all except one having two glands. Corolla yellow. Native of the iſland of Dominique [e].

4. Stem ſhrubby, twining. Branches oppoſite, horizontal, diverging, ſtrict, long, round, ſmooth, ſomewhat compreſſed at the top. Leaves petioled, oppoſite, ſmooth on both ſides and ſhining, rigid, bright green. Branches of the raceme oppoſite, ſpreading, ſimple, many-flowered. Pedicels longiſh, filiform, one-flowered. Flowers ſmall, blue. At the exterior baſe of the calyx are ſmall green ovate ſeſſile glands. Petals five, clawed, roundiſh, broadiſh, waved and crenulate. Capſules three, diviſible, each three-winged: the hinder wing a little bigger than the others, oblong, tranſverſe, except the middle one, which is minute.

Native of Hiſpaniola: flowering in may. It is nearly allied to T. jamaicenſis, but the leaves are very different, being rounder, very rigid, and marked with ines [f].

5. Branches round, woody, ſmooth, as is the whole plant. Leaves on ſhort petioles. Peduncles jointed, two-ſtipuled. Calyx hemiſpherical. ſegments ovate, one naked, the four others biglandular. Petals equal, yellow, very ſmall. Filaments ſhort, awl-ſhaped, widening at the baſe, and united into a concave body, ſupporting the germ. Germs three, united, ſomewhat roughened with rudiments of wings. Capſules three, globular, girt on the outſide with a longitudinal membrane, at the ſides of which are here and there ſhort membranaceous fringes: wings ſubovate, equal. Seed ſomewhat three-ſided. Native of Cayenne.

6. Branches round, ſmooth, oppoſite. Leaves quite entire, coriaceous, on ſhort erect petioles. Rays of the umbel five or more, half an inch long, jointed, having two ſtipules at the joints. There did not appear any glands on the calyx in the dry ſpecimen. Germs three, tomentoſe, united. Wings of the capſules four, ovate, the upper ones a little longer than the lower: the capſules keeled, and augmented by three acute corpuſcles, two of which are lateral, and the third hangs down between the lower wings. Seed ovate. Native of Cayenne.

7. Stem round, with a brown bark, and roughened with ſmall tubercles. Leaves ſubſeſſile, reſembling thoſe of Box. Rays of the umbel four or more, an inch long, jointed, two-ſtipuled, one-flowered. Glands of the calyx eight, pedicelled. The reſt as in the preceding; but the capſules ſmaller. Native of the Antilles [g]. Cavanilles's Baniſteria microphylla, *p.* 429. *n.* 588. is the ſame with this.

8. Stem ſhrubby, climbing very high. Branches very long, flexile, round, ſmooth. Leaves oppoſite. entire, nerved, veined, membranaceous, large, on ſhort petioles. Branches of the umbels or panicles trichotomous, ſpreading, pedicels one-flowered. Leaflets ovate acute alternate ſeſſile, ſcattered over the branches of the panicle. Flowers ſmall, yellow. At the baſe of the ſegments of the calyx on the outſide are two brown gibbous nectareous glands. Petals five, roundiſh, waved, veined, with linear claws. Filaments awl-ſhaped, contiguous at the baſe. Germs three, united: ſtyles three, thickened at the top: ſtigmas acute. Capſules three, ovate, ſeparable; each four-winged: two oppoſite wings larger, veined, two ſmaller; and a fifth intermediate like a creſt. Seed large, ſhining, red [h].

Native of South America, Jamaica and Dominique.

[3. Trioſteum triflorum.

Lin. ſpec. ed. Willd. 1. 991. *Vahl ſymb.* 3. 37.

Peduncles oppoſite three-flowered, leaves petioled.]

DESCRIPTIONS, *&c.*

1. This has a perennial root compoſed of thick fleſhy fibres, which are contorted and rough. Stems ſeveral, ſtrong, herbaceous, riſing a foot and half high; having at each joint two oblong broad leaves embracing the ſtem. From the boſoms of theſe come out the flowers in whorls, ſitting very cloſe to the ſtem; they are ſmall, of a dark red colour, inclining to purple, and appear the beginning of june.

[Berry ovate-globular, crowned with a long calyx, pulpy, yellow, one-celled; pulp before it is fully ripe ſpongy and growing cloſe about the ſeeds; which are three, biggiſh, bony, elliptic, on one ſide convex with three thick ridges, on the other obſcurely angular or flattiſh with a ſingle ridge along the middle[1].

Linneus and Miller deſcribe the fruit as three-celled. Gærtner as one-celled. The latter ſuſpects that the ſeeds were not ripe in his ſpecimens.

Native of North America. Cultivated in 1732, by James Sherard, M. D.*—Bobart ſays, that he had the ſeeds of this and the next ſpecies from Baniſter.]

2. This differs from the firſt in having longer and narrower leaves. The flowers ſtand ſingle upon ſhort peduncles, and there are but two at each joint, whereas the other has many growing in ſeſſile whorls round the ſtalks.

The roots of both theſe plants are uſed indiſcriminately in North America, as an emetic, for Ipecacuanha. One of the firſt perſons who brought their roots into uſe was Dr. Tinkar, whence many call them Dr. Tinkar's weed; and Bobart received this ſpecies from Baniſter by that name. The leaves of the firſt ſort greatly reſemble thoſe of the true Ipecacuanha, but the roots are of a different form. Mr. Miller conjectures that the true one is a ſpecies of this genus, [but it is now ſuppoſed to belong to the Pſychotrias, which ſee.

3. Stem erect, a foot and half high, ſimple, very finely pubeſcent. Leaves oppoſite, ſpreading very much, two or three inches long, lanceolate, as narrow again as in T. perfoliatum, attenuated at the top, quite entire, above ſimply veined and ſmooth, beneath ſoftly villoſe, hoary, with branching veins; when tender tomentoſe-hoary beneath. Petioles pubeſcent, ſhorter than the ſtipules; which are wide at the baſe, awl-ſhaped, preſſed cloſe, ſcarcely half an inch long. Peduncles axillary, ſolitary, erect, pubeſcent, three-flowered: with two awl-ſhaped bractes at the tip, a little ſhorter than the calyx. Flowers ſeſſile. Segments of the calyx awl-ſhaped. Fruit oblong, ſmooth, a little longer than the ſegments of the calyx, and crowned with the permanent calyx. Suppoſed to be a native of Madagaſcar. Sent to Vahl by Monſ. Thouin[1].]

PROPAGATION AND CULTURE.

The two firſt ſorts are hardy enough to thrive in the open air, but ſhould be planted on a moiſt light ſoil: on dry ground they muſt be watered conſtantly in dry weather.

Sow the ſeeds on a border of light earth, where the morning ſun only comes: if they be ſown in the ſpring, they will remain in the ground a whole year, during which time the border muſt be conſtantly kept clean; the following ſpring, when the plants appear, water them duly in dry weather: but if they be ſown in autumn they will come up the following ſpring. Keep them conſtantly clean, for if weeds be permitted to grow among them, they will ſoon overbear the plants while they are young, or ſo much weaken them that they will not ſoon recover.

The plants may remain in this ſeed-border until the michaelmas following, when they ſhould be carefully taken up, and tranſplanted where they are deſigned to remain. Some ſhould be planted in pots, that they may be ſheltered in winter while young, leſt thoſe which are in the full ground ſhould be deſtroyed by ſevere froſt.

They may alſo be increaſed by parting the roots in the ſpring, juſt before the plants begin to ſhoot, which is commonly about the middle or end of march: but in doing this, the roots muſt not be parted too ſmall, for that will prevent their flowering ſtrong.

Theſe plants perfect their ſeeds in this country every year. The ſeedling plants will not flower until the third year.

DESCRIPTIONS, *&c.*

1. This is an upright elegant tree, with a trunk the height of a man, and a thin head made up of horizontal branches forming a long pyramid. Leaves oblong-ovate, acuminate, very large (a ſpan long), entire, petioled. Spikes long, ſlender, erect, terminating, (hairy; with ſmall ovate acuminate hairy bractes. *Linn.*) Nut ovate-acuminate, of a very ſmooth and ſhining black, ſharp at the angles, one-celled; containing a kernel of the ſame form. By the ſide of this nut ſtand three leaflets, preſſed cloſe to it, which are flat, wedge-oblong, obtuſe, nearly the length of the nut, rufous; which Jacquin would have taken for permanent petals, if Loefling had not ſaid that there is no corolla: perhaps, he ſays, they are filaments. According to Aublet, they belong to the calyx.

Native of South America.

2. This is a branching diffuſed tree. Leaves ovate or roundiſh ovate. Racemes on the branches, cloſe, from half an inch to an inch and half in length, many-flowered, villoſe. Pedicels hirſute, ſhort, ſcatteringly aggregate on the common peduncle, from two to five together, from a little bracted knob. Fruit a little ſmaller than the preceding. Tube of the calyx villoſe, but not hairy; alſo more round. Nut brown, not ſhining; ovate, ſix-grooved not three-ſided. The three leaflets, which Jacquin ſuppoſes may be filaments, permanent, and ſomewhat linear. The kernels

[1] Gærtner. * Hort. kew. [1] Vahl.

Digitized by Google

kernels in both ſpecies have an aſtringent ſubacrid taſte.

Native of the woods about Carthagena, but more rare than the preceding; by the river Cinu it is more common[a].]

Claſſ. 21. 3. Monoecia Triandria.

Nat. order of *Gramina*, *Gramineæ* or *Graſſes*.

GENERIC CHARACTER.

* *Male* flowers double on one ſide alternate, in the upper part of the ſpike.

CAL. *Glume* two-flowered: outer floret male, inner neuter; each two-valved: outer valve lanceolate, flattiſh, obtuſe, awnleſs, cartilaginous, with the margins thinner (the interior one ſtraightiſh) embracing the interior oblong, triangular-boat-ſhaped, acute, almoſt the length of the exterior.

COR. in each two-valved, membranaceous, very thin, awnleſs, leſs than the calyx: *valves* nearly equal: exterior ovate, boat-ſhaped, bluntiſh; interior anceolate, bifid at the top.

Nectary two-leaved, very ſmall: *leaflets* triangular, fleſhy, convex, truncate, mucronate at both ends, the upper margin thinner, the middle emarginate.

STAM. of the outer Floret; *Filaments* three, capillary, longer than the calyx. *Anthers* parallelopiped:—of the inner Floret: *Filaments* three, very ſlender, ſubconnate. *Anthers* none.

* *Female* flowers on the ſame ſpike below the males, immerſed alternately on each ſide into the rachis.

CAL. *Involucre* ovate, cartilaginous, very thick, ventricoſe below, ſhining, obſcurely margined on both ſides at the back, ſubemarginate with a blunt top, embracing the glume with a thinner margin.

Glume two-valved: *outer valve* oblong, ventricoſe, attenuated at the top, acuminate, thickiſh, doubled; *inner* ſimilar, bluntiſh.

COR. two-valved, ſmaller than the calyx and more tender: *outer valve* larger, ventricoſe, bluntly three-toothed; *inner* ſcarcely ſmaller, flat at the back, emarginate. *Glume* barren, one-valved, oblong, folded together at each margin, two-toothed, by the anterior ſide of the corollet, and much ſmaller than it.

Nectary two-leaved, very ſmall: *leaflets* linear, membranaceous, very thin, acutely emarginate at the top.

STAM. *Filaments* three, at the baſe of the germ, very ſmall, broad at the baſe, capillary. *Anthers* linear, very ſmall, barren.

PIST. *Germ* oblong. *Style* longer than the calyx, compreſſed. *Stigmas* two, very long, twiſted, villoſe.

PER. none.

SEED one, ovate, compreſſed a little, acuminate with the permanent ſtyle.

OBS. *At the baſe of the involucre on each ſide is a ſinus, gaping externally with an aperture, blocked up by villoſe hairs.*

ESSENTIAL CHARACTER.

MALE. *Cal.* Glume four-flowered. *Cor.* Glume membranaceous.

FEM. *Cal.* Glume with perforated ſinuſes. *Cor.* Glume two-valved. *Styles* two. *Seed* one.

Spike hermaphrodite.

DESCRIPTIONS, *&c.*

1. Leaves an ell or more in length. Culms the thickneſs of a gooſe-quill or of the little finger, with few joints and long internodes, angular, tinged with purple, as high as a man, dividing at top into three, four or five ſpikes, a long ſpan or a foot in length, and ſtraight[b]. Native of Virginia.—Parkinſon ſays, Maſter John Tradeſcant the younger brought it from Virginia, with a number of other ſeeds and rare plants. —It muſt therefore have been introduced before 1640. It flowers in auguſt[c].

2. Root annual, fibrous. Culm erect, two feet high, roundiſh, very ſmooth, jointed, branched. Branches of the ſame ſtructure and height with the culm, alternate, erect, quite ſimple, few. Leaves alternate, flaccid, very ſmooth, only rugged at the edge, a ſpan long or more: ſheaths compreſſed, ſtriated, very ſmooth. A ſingle ſpike at the end of the ſtem and branches, ſolitary, cylindrical, curved. Peduncle long, round, ſtriated, ſmooth. Receptacle compreſſed, flexuoſe. Flowers alternate, remote, ſolitary, ſeſſile on the teeth of the receptacle, ovate, preſſed cloſe. The outer calyx has two, three or four flowers: glume four or five-parted, compreſſed, ovate, gibbous at the baſe, contracted at the top; the valves incumbent, very ſtiff, lanceolate, acuminate, very ſmooth, ſlightly ſtreaked. There is a ſingle floret between each calycine glume, leſs by half than the calyx. Calyx two-valved: one valve ſmaller, very long and acuminate; the other of the ſame ſize with the corolla, which is alſo two-valved, ſmooth and acuminate. Filaments ſmooth: anthers ovate. Germ ovate: ſtyles two, pubeſcent. Seed one, very ſmall, ovate, ſmooth, yellow, ſubdiaphanous. Native of Jamaica[d]; where Browne ſays this graſs is fed upon by all ſorts of cattle.

Introduced in 1776, by Monſ. Thouin. It flowers in auguſt and ſeptember[e].

The firſt is a perennial graſs, and tolerably hardy. The ſecond is annual, and requires the protection of a ſtove.

TRITICO-SPELTUM. See *Hordeum*.]

TRITICUM (*Latin, q.* tritum, *vel quod ex ſpicis* triturando *facile excutiatur. In Greek,* πυρος *q.* σπυρος, *from* σπυρος, *ſeed. Or, according to ſome, from the conical form of the ſpike, like a flame.*)

Claſſ. 3. 2. Triandria Digynia.

Nat. order of *Gramina*, *Gramineæ* or *Graſſes*.

GENERIC CHARACTER.

CAL. a common *Receptacle* elongated into a ſpike.

Glume two-valved, ſubtriflorous: *valves* ovate, bluntiſh, concave.

COR. two-valved, nearly equal, ſize of the calyx; *exterior valve* ventricoſe, blunt with a point; *interior valve* flat.

Nectary two-leaved: *leaflets* acute, gibbous at the baſe.

STAM. *Filaments* three, capillary. *Anthers* oblong, forked.

PIST. *Germ* turbinate. *Styles* two, capillary, reflexed. *Stigmas* feathered.

PER. none. Corolla ſoſters the ſeed, opens and drops it.

SEED one, ovate-oblong, blunt at both ends, convex on one ſide, grooved on the other.

OBS. *The exterior valve of the corolla in ſome is awned, in others awnleſs. The middle floret is often male.*

[a] Jacquin. [b] Moriſon. [c] Hort. kew. [d] Linn. fil. dec. [e] Hort. kew.

ESSEN-

ESSENTIAL CHARACTER.

Cal. two-valved, ſolitary, ſubtriflorous (or many-flowered, on a flexuoſe toothed rachis.) *Cor.* blunt with a point.

DESCRIPTIONS, *&c.*

1. Haller deſcribes the Spring Wheat, as having the firſt or lower flowers imperfect; the ſpikelets wide; the glumes of the calyx hard, glaucous, ſomewhat hairy, very ſhortly awned; flowers three to five, with an awn from the exterior glume three inches long; the interior glume convex towards the ſeed, concave towards the next flower, ovate-lanceolate; the third flower, in the middle has a very ſhort awn; the fourth is ſterile and ſhrivelling; the fifth is ſtill ſmaller and more imperfect. He ſays, it is ſown about Aigle.

He does not allow that it is ſpecifically different from Winter or Lammas Wheat, or that the having awns or no awns makes any diſtinction. Soil and climate, he ſays, will do much in that reſpect; winter Wheat will grow from the ſeed of ſpring Wheat; and if the former be more fruitful, that is probably owing to its having been a longer time in coming to perfection.—There is no doubt however but that Spring Wheat is a diſtinct ſpecies.

Summer Wheat, ſays Parkinſon, has narrower ears, longer beards, and ſmaller grains, and will not endure the coldneſs of our winters.]

This will ripen, ſays Miller, much earlier, and therefore has been often ſown in the ſpring, at the ſame time with oats; but if the ſeaſon ſhould prove wet, it is very ſubject to grow tall, and to have very thin grains; ſo that unleſs from the ſeverity of the winter, or ſome other accident, the winter corn has been injured, the practice of ſowing Spring Wheat is rarely uſed.

[The experienced reporters of the county of Northumberland, for the Board of Agriculture, inform us that Siberian or Spring Wheat was introduced and ſtrongly recommended about twenty years ſince; but that wherever they have ſeen it tried, the crops have been uncertain, and the produce ſmall; and that though this flinty kind will ripen, if ſown even as late as april, or beginning of may, yet it has not been able to maintain a ſtruggle with ſome of the varieties of Lammas Wheat, and has been totally given up[r].

In the report for Mid-Lothian[s], it is ſaid, that a very particular kind of Spring Wheat was ſown eight or ten years in the vicinity of Edinburgh. It admitted of being ſown as late in the ſeaſon as the end of april or beginning of may, and was ripe in auguſt or ſeptember, producing very weighty grain, and as high as eight bolls an acre. It did tolerably well

[r] P. 69. [s] P. 91. note, ed. 1795.

Digitized by Google

for a year or two, but one inclement ſummer, in 1792, completely finiſhed it, the crop, all blacked or blighted, being good for nothing; and it has not been heard of ſince.

In the year 1788, Mr. Young informs us, that Mr. Ducket of Eſher in Surry cultivated Spring Wheat on a large ſcale; drilling two buſhels of it on an acre, about the middle of march [t].

Mr. Marſhall, in his rural œconomy of the Midland Countries, ſays that Spring Wheat is there cultivated, and with ſingular ſucceſs; owing principally to the time of ſowing, in the wane of april. By ſowing early, as at the beginning of march, the grain is liable to be ſhrivelled, and the ſtraw to be blighted; whilſt that ſown at the middle or end of april, or even the beginning of may, produced clean, plump corn.

Mr. Tooſey mentions a Spring Wheat which he ſowed in Canada on the third of may, and reaped the 26th of auguſt. He ſowed a pint, and reaped a buſhel [u].

In the Aſiatic Reſearches, a ſpecies of Wheat is mentioned as cultivated in the Eaſt Indies, which has the calyx four-flowered, ventricoſe, ſmooth, and imbricate: the two outer florets have long beards, the third has hardly any, the fourth and innermoſt is neuter. The deſcription ſeems to agree with the Spring Wheat; but according to the author it is doubtful whether it ſhould be referred to that or to Spelt; or whether it may not be a new ſpecies, rather variety. It was in ear at Oujein on the 30th of january, and ripe on the 19th of march.—The Barley crop is ripe in that country the beginning of march.]

2. Common or Winter Wheat has long ears or ſpikes, with the grains ranged in four rows, and imbricate; the chaff ſmooth, ventricoſe or bellied, and not terminated by awns or beards. [The laſt character however is not conſtant, for Winter or Lammas Wheat, has frequently ſhort awns, but they never grow to the length of thoſe in Spring Wheat.

Wheat may more properly be conſidered as an annual than a biennial plant, as it not only ripens within a year from the time of ſowing, although it commonly takes a part of two years to accompliſh this; but it will run its courſe in ſix months, or leſs time in countries to the north of Great Britain.

Dr. Hunter (Eſſay 5.) has very well remarked that Wheat has two ſets of roots; the firſt coming immediately from the grain, the other ſhooting from the crown ſome time after: the firſt he calls the *ſeminal*, and the ſecond the *coronal* roots.

Plants obſerve a regular uniformity in the manner of ſpreading their roots; for which reaſon the ſame grain cannot in general be continued long on the ſame ſoil.

Wheat being ſubject to the ſeverity of winter, its roots are wonderfully diſpoſed to withſtand the inclemency of the ſeaſon. The firſt, or ſeminal root is puſhed out at the ſame time with the germ; and that, together with the meal, nouriſhes the plant, until it has formed the crown. When this has become ſufficiently large, it detaches a number of ſtrong fibres, which puſh themſelves obliquely downwards. Theſe are the coronal roots. A ſmall pipe preſerves the communication between them and the ſeminal roots. It makes an eſſential part of the plant, and is obſerved to be longer or ſhorter, according to the depth at which the ſeed has been buried. The crown however is always formed juſt within the ſurface; and its place is the ſame, whether the grain has been ſown deep or ſuperficially.

As the increaſe and fructification of the plant depends upon the vigorous abſorption of the coronal roots, it is no wonder that they ſhould fix themſelves ſo near the ſurface, where the ſoil is always the richeſt.

The ſtalk, ſtraw, or culm as Linneus calls it, is three feet high at a medium, jointed, ceſpitoſe or in tufts; ſeventy-two have been known to iſſue from one root. Leaves ſmooth, three lines wide; much more, and of a very dark green in good ground. Spike cloſe, weighty, ſome inches in length. The lowet flowers imperfect, as is commonly the caſe in this order of plants. The glumes or chaffs of the calyx are ovate-lanceolate, and end in a point like a ſhort awn; they contain for the moſt part each four flowers, but there are ſometimes only three, and ſometimes five or ſix, but then one or more of theſe fall off without producing any grain. The two glumes or chaffs of the corolla are equal, but the outer one puts forth an awn a little below the tip, an inch or two inches in length; ſometimes however there is none; the inner one is hollow, awnleſs and two-toothed: between theſe lies the ſeed or grain, which is villoſe, and the largeſt of its congeners. The nectaries are ſmall, fringed and ſilky [x].

Gærtner deſcribes the ſeed as ovate, acuminate at each end, pubeſcent at the top, convex-three-ſided on one ſide, ſcored with a deep groove on the other, the colour of honey or ſubruſeſcent. The embryo has three radicles.]

Where Wheat grows naturally, ſays Mr. Miller, is very hard to determine at preſent; but it is generally ſuppoſed that Africa is the country, becauſe in the earlieſt accounts we have of it, there is mention of its being tranſported from thence to other countries, and Sicily was the firſt country in Europe where this grain was cultivated: but although the place of its natural growth be probably in a warm climate, it is found to bear the inclemency of our rough climate very well; and even in more northern countries, where the ſummers are long enough to ripen the grain, it is found to ſucceed.

[Even Wheat, ſays Bruce, the early produce of Egypt, is not a native of it. It grows under the line, within the Tropics, and as far north and ſouth as we know. It vegetates vigorouſly under ſnow. But whence it came, and in what ſhape, is left to conjecture.

It is aſſerted that Spring Wheat, and Sprat Barley (Hordeum diſtichon) grow wild in Tartary: and Diodorus Siculus affirms that Wheat is wild in Sicily; that it may have come up ſpontaneouſly in that iſland is very probable, but that it is originally indigenous there is not at all likely.

Varieties.

The principal varieties of Winter Wheat are, the White and Red without awns (α, β, γ.) and the Red and white Bearded Wheat (δ, ε). Of theſe there are innumerable ſubordinate varieties.]

Some of theſe, ſays Mr. Miller, differ in the colour of their chaff, and others in the form of their ſpikes, but they are ſubject to vary. He enumerates only, the Red Wheat without awns, the red-eared Bearded Wheat, many-eared Wheat, (probably n. 3.) and naked Barley. Theſe five ſorts, he ſays, I have ſown ſeveral years, and have always found them conſtant without variation.

[Mr. Houghton, in his Collections, publiſhed at the end of the ſeventeenth century, has ſeven varieties, from Mr. Dale, the friend of Mr. Ray, but three of theſe do not belong to this ſpecies, namely the double-eared (to n. 3.) Poland Wheat (to n. 5.) and the Gray Pollard (to n. 4.)

The other four are: 1. Triticum ſpica et granis albis. *Raii hiſt.* 1237. 2. our γ. White Wheat, called Egg-ſhell Wheat in Eſſex, by ſome. Proſpers beſt in heavy clay and loam; ſometimes found with awns, but rarely.

2. Tr. grano albo, glumis hirſutis; called Mouſe-dun, or by ſome Egg-ſhell Wheat in Eſſex, from the colour of the hairy chaff when ripe, and in which it chiefly differs from the former, being frequently ſown together in our rich and light lands.

3. Tr. ſpica & granis rubentibus. *Raii hiſt.* 1237. 1. Red or Kentiſh Wheat. Much ſown in Hertfordſhire, and ſometimes found with awns:—perhaps tritici varietas culmo rubro, *Raii ſyn. app.* which Mr. Bobart ſays is ſo much deſired in Oxfordſhire, may be only a variety of this.

4. Tr. ſpica multiplici. See our Tr. compoſitum n. 3.
5. Poland Wheat, n. 5.
6. Tr. ariſtis circumvallatum, granis & ſpica rubentibus, glumis lævibus & ſplendentibus. *Raii ſyn.* 387. Red-bearded Wheat—our *δ*.
7. Tr. ariſtatum ſpica maxima cinericea, glumis hirſutis. *Raii hiſt.* 1238. Gray Pollard—our n. 4.[t]

It would be almoſt endleſs, and of little uſe, to enumerate all the varieties of Wheat, which are continually introducing, and giving way to new ones. It will however be expected that the more remarkable ones at leaſt ſhould be ſet down in ſuch a work as this. An alphabetical catalogue of them therefore is here given.

1. Aleppo. Spikes ſhort and awned. Chaffs whitiſh and ſmooth. Grains ſhort and turgid or big. From the neatneſs and beauty of the ſpike the orientals call it *Joſeph*; which name they uſe for any thing more than ordinarily handſome, in honour of the Patriarch, who was ſo eminent a patriot in Egypt.

   There are other varieties from Aleppo—as *tripolitanum granis nigricantibus* of Parkinſon, with ſpikes a hand in length, and very long awns; the grains long, very dark-coloured, reſembling Rie. This is much taller than the preceding—and another that is lower, with reddiſh grains, and long blackiſh awns[u]. Smyrna Wheat belongs to this variety.
2. Bearded. See *Tr. turgidum, n.* 4.
3. Brazil. Sown on ſtrong land in Somerſetſhire.
4. Burwell. Ears long and large; ſpiculæ very wide ſet, nine in three inches and three-fourths; chaff a dark brown red, large and cloſed on the grain; ſtraw long red. Much uſed in the north, eſpecially on lands newly broken up, and has in a manner ſuperſeded the common red Wheat[x].

   Burwell ſeed Wheat grows on white lands in the pariſh of Burwell in Cambridgeſhire. It is in great requeſt in the north of England, on account of its becoming ripe much ſooner than any other that is known. It is partially threſhed (provincially, topped out), as ſoon as it is got into the barn; ſo that it is the ripeſt and beſt part of the ear that is obtained from it[y].
5. Cane. See *Tr. turgidum, n.* 4.
6. Dantzick. Lower in the ſtraw by ſix inches than common Wheat, and very regular: ear downy, white; ſtraw white: it does not lodge, and is leſs ſubject to blight and ſmut than other ſorts. Uſed for ſeed about Caverſham, &c. in Berkſhire[z].
7. Double Wheat. See *Tr. compoſitum, n.* 3.
8. Duckbill. See *Tr. turgidum, n.* 4.
9. Dunover. See *Tr. turgidum, n.* 4.
10. Egg-ſhell or White. Straw white; chaff ſmooth and white; grain white, with the bran ſomewhat thick, but the flour remarkably white. It is very early ripe, and ſo free in the ear as to blow out in windy weather; it works mellow in grinding. From rich ſandy loams it is often a beautiful ſample; and when ſo, brings the higheſt price of any ſort[a].
11. Eſſex Dun. Similar to the Kentiſh White-chaffed (which ſee:) and the Hertfordſhire Brown of Yorkſhire. It has been making its way into the Midland counties. Thoſe who have given it a fair trial, like it on account of its giving a great produce; four or even five quarters on an acre[b]. See var. 2. from Houghton, above.
12. Eſſex White. Only a good ſample, as I believe, of the White Lammas.
13. Fulham. Straw white, ſhort and coarſe. Very productive, eſpecially on poor land; but the grain very coarſe and the bran thick: from which circumſtances it is not ſo valuable to the millers[c].
14. Golden-ear. Ear ſhort; ſpiculæ very cloſe ſet, nine in two inches and three quarters; chaff a yelloviſh light brown, ſhort; grain white, and eaſily ſhaken out by the wind.

   For ſpring ſowing, this and the Burwell red are preferred in the northern counties, except where the land is in ſuch high condition as to endanger the crop lodging; then the Velvet-ear is uſed, as not being apt to lodge, from the ſhortneſs of the ſtraw[d].
15. Gray Pollard, Pole or Poll-revet or rivet. See *Triticumm turgidum, n.* 4.
16. Harriſon's Kentiſh Red. See Kentiſh Red.
17. Hedge. White. This variety was diſcovered by accident in a hedge, by Mr. Wood of Suſſex, who carefully cultivated it from the ſingle grain, and the produce in four years, by his attention, was wonderful. It is now (1795) generally known in Surrey as well as Suſſex; and has ſince been extended to ſome of the midland counties. The produce is very great: thirty-ſeven truſſes of ſtraw having yielded, in a bad year, twenty buſhels and one peck of capital Wheat, ten ſheaves yielding one buſhel throughout. The ſame year, four buſhels ſowed on very middling wheat land produced twelve ſacks and one buſhel, of a remarkably fine ſample[e].
18. Hertfordſhire brown. Chaff white; grain red; ſtraw of a middle growth: reſembling the Kentiſh white-coſh of Norfolk[f]. See Eſſex Dun, n. 11.
19. Hertfordſhire White; the ſame with Eſſex White (n. 12.) and an improvement of White Lammas.
20. Hoary Brown. A new ſort introduced into Kent, within the laſt twenty or thirty years[g].
21. Hoary White, or White Hoar. Straw, ear, and grain white. Mr. Young ſays it is diſtinct from Velvet ear; which ſee.
22. Holland White. See White Holland.
23. Kentiſh 1. Downy. Chaff white, downy, awnleſs; ears middle-ſized; grain white and ſmall; ſtraw ſhort. This variety is beſt adapted to good land, in which it generally yields well, notwithſtanding the ſmallneſs of the grains[h].—2. Red. Harriſon's Kentiſh Red, ſo named from a farmer who produced the firſt ſample of it, by cultivating ſome ears which he obſerved to be more cloſely ſet, and more productive than the wheat in general in the ſame field. The chaffs appear to be ſhorter than common. The produce of twelve acres, in 1785, on a clean ſummer fallow, without manure, was a hundred and forty-one coombs, three buſhels, of very fine wheat[i].—3. White or white-ſtrawed, or white-chaffed, called Kentiſh White-coſh in Norfolk. It ſends out a great number of ſtems, and therefore is often a very thick crop. The ſtraw is generally ſomewhat ſhorter than that of many other varieties, and therefore not quite ſo liable to fall in rainy ſeaſons. The ears are middle-ſized, nine ſpiculæ in three inches and a quarter; chaff white, opening and ſhewing the grain when ripe; grain plump and red, reſembling very much the Velvet Wheat of Surrey and Kent. The produce allowed to be greater than that of the old red; and the millers, according to Mr. Marſhall begin to like it nearly as well, though on its firſt introduction fifteen or twenty years ago, they were prejudiced againſt it. The Kent ſurveyor ſays, that from its dull colour, thick bran, and grinding very ſteely, it is not much approved of by the millers[k].—This variety, though the chaff be perfectly white on its introduction into Norfolk, and though it be ſtudiouſly kept ſeparate from the red; yet by being repeatedly ſown year after year, it loſes the fair-

neſs

neſs of the chaff, which firſt becomes pied, and at length changes entirely to a clear red, reſembling that of the old Norfolk ſtock [l].—4. Yellow. Chaff ſomewhat red. Grain white. Ears large. Straw ſtout [m].

24. Lammas. 1. Brown. This is the common brown-ſtrawed Wheat: it grows with a long jointed ear, the chaff of a dark brown colour; the ſtraw is long and apt to fall; the hull or bran thin, and the flour very white; and the corn mellow in grinding: for which reaſons it is eſteemed by the millers. Till within theſe twenty or thirty years paſt, this was the ſort chiefly cultivated in Kent, but it has ſince been giving way to many new varieties, as well as ſome of the other old ones. By ſome experiments made by Mr. Boys of Betſhanger it appears that this was leſs productive than ſeveral other varieties [n].—2. Mixed. With an awnleſs whitiſh ſpike, and reddiſh grains [o]. Probably the ſame with the White Kentiſh Wheat.—3. Red. This is the ordinary Red Wheat of the kingdom; with the ſpike or ear and grains red, the ſtraw red or dark yellow. It is ſuperſeded in many places by improved varieties. One which obtains much on the Suſſex downs is called Clark Wheat, from the perſon who firſt introduced it; the bloſſom, chaff, and ſtraw are red; the grain is white; the ſample is coarſe, but it yields greatly; it requires to be cut forward [p]. Another, cultivated on the hills and all expoſed ſituations in Somerſetſhire, called the red-ſtraw, differs from the red Lammas in having every bloſſom of a purple colour [q]: the ſtraw alſo is red or purple, and the grains are red [r].—4. White. This, which is the old White Lammas of the kingdom, is now ſuperſeded, like the old Red, in many places, by new varieties. The chaff and grains are both white, and the ſtraw is of a pale colour.—5. Yellow. This reſembles the Brown in every reſpect, except that the colour of the grain is yellow, and the chaff is of a ſomewhat lighter colour [s].

25. Long Cone. See *Tr. turgidum*, *n.* 4.

26. Nonpareil. Said to be brought from America. It has a bright ſtraw with a brown ear, and the grain is very white, large and plump. Very productive on all ſoils, thraſhes very free, and produces a great quantity of horſe-meat. It grinds very mellow, and is well eſteemed by the millers.

27. Pendulum. See *Tr. turgidum*, *n.* 4.

28. Pilbeam. A brown wheat, growing very ſtiff, and generally thick on the land. The grain ſmall and plump, ſomewhat of a yellow brown. It is ſaid to be very productive on rich lands, and is valuable to mix with others, but will not of itſelf make good bread, becauſe it does not ferment eaſily [t].

29. Poland. See *Tr. polonicum*, *n.* 5.

30. Pole or Poll Rivet. See *Tr. turgidum*, *n.* 4.

31. Pollard. See *Tr. turgidum*, *n.* 4.

32. Quebeck. A white wheat from America [u].

33. Red-poll-rivet. See *Tr. turgidum*, *n.* 4.

34. Red-ſtraw. See Lammas, n. 24. 3.—It is generally eſteemed in Staffordſhire, as being hardy upon cold wet land; carrying a length of ſtraw upon dry ſands, and thereby over-topping fern and other luxuriant natives; and the grain overweighing every other ſort.

35. Spaniſh.—Mr. Dillon has given a liſt, with remarks, of twenty-five varieties of Spaniſh Wheat, divided into four claſſes:—1. Candeal, or White Wheats. 2. Geſas. 3. Claros. 4. Rubion, or Red Wheats.

He remarks that the Spaniſh Wheats are hard and ſteely, and that the flour here is ſaid not to exceed in fineneſs that of the third ſort in England and Ireland [v].

36. Square-ear. One of the new varieties introduced into Kent. It is very productive, but being apt to drop out before it is ripe, and to blow out in gales of wind, it is not much cultivated [x].

37. Square Gray. See *Tr. turgidum*, *n.* 4.

38. Stuffed. See Velvet-ear.

39. Taunton Dean. So called from the place it was originally brought from. It is a bright and beautiful grain, and very productive; near four quarters on an acre [y].

40. Velvet-ear, or hoary White. Straw white and ſhort: ears ſmall, but the grains cloſe ſet, eight in two inches and three quarters; chaff white (or ſomewhat of a browniſh hue), covered with a thick fine down, cloſed on the grain; which is ſmall and of a dull white; the ſkin very thin, ſo that ſome grains are almoſt tranſparent when held up to the light. It grinds very mellow, and makes a beautiful fine white flour. From the quantity of down upon the chaff, and its ſmall ears binding up very cloſe in the ſheaf, in a rainy ſeaſon it is apt to grow in the field; on which account it is not ſo proper to cultivate in a moiſt climate, and in ſmall incloſures, that are not open to wind and ſun [z]. From the ſhortneſs of the ſtraw, it is beſt adapted to rich ſoils, where there is a danger of the crop lodging [a].

Of the ſeveral varieties cultivated in Suſſex this is preferred, having by much the thinner ſkin of any: they call it ſtuffed Wheat [b].

In the year 1768 Mr. Arbuthnot gathered ſix ears of Wheat, the down on them attracting his notice. He ſowed it, took off the tillers and tranſplanted them, repeating the operation, and ſetting them in the middle of a field of beans. The plants ran away for ſeed, before their own tillers came into ear; ſo that if this practice were to be followed, there would be the difference of a fortnight in the ripening of the ears of the ſame plant.

The product of the ſix ears was fourteen quarts, which were drilled on one acre in four rows, eight inches aſunder, on four feet ridges: the produce three quarters three pecks. Mr. A. continued the culture of it till he grew no other, and ſold great quantities for ſeed. In 1779 Mr. Arthur Young introduced it into Suffolk, and in the five following years, on compariſon with the common red wheat of the country, he found the ſuperiority of produce in the Velvet Wheat, to be from two to ſix buſhels on an acre. But he found the quality to be ſtill more ſuperior, for on an average he ſold it at ſixpennce a buſhel more than the Red Wheat. Velvet Wheat is lighter than Red Wheat; but the latter has a much greater quantity of bran. A crop of this ſort of Wheat is of very regular growth. The ears are very ſhort, not from the ſmall number of grains, but from being very cloſe ſet, and much enveloped in chaff. When ripe, the ſtraw is of a bright white, but the ear of a red colour. From conviction of the ſuperiority of this wheat to the common ſorts, Mr. Young had no other on his farm in 1785, and did not then intend to ſow any other [c].

Mr. Hall, of Elmſtone-Court in Kent preferred this Wheat to any other. And by the experiments of Mr. Boys of Betſhanger in the ſame county it appears, that this, which is there called Hoary White, is the beſt to cultivate on good dry loamy ſoils, and very far ſuperior to the common brown Lammas, which is commonly ſown there [d]. Mr. Dann of Gillingham alſo ſays that the Hoary White or Velvet-eared produced him much more than the Red Wheat [e].

41. White Egg-ſhell. See Egg-ſhell.

42. White

Digitized by Google

42. White Holland. A white foreign wheat, not very different from the Kentiſh white. Produce conſiderable. See Zealand.
43. White-ſtraw. See Kentiſh white-ſtraw, n. 23. 3.
44. White Zealand. See Zealand.
45. Whole-ſtraw.
46. Woolly-ear. Straw long; ears middle-ſized; ſpiculæ cloſe ſet, nine in three inches; chaff white, cloſed on the grain, which is white, larger, longer, but not ſo plump as the Velvet-ear: the appearance of the ear is larger in every dimenſion.

The downy-chaffed Wheats (this and n. 40.) have ſhorter ſtraw, and are leſs liable to have the grain ſhaken out by winds, than the ſmooth-chaffed ones, which is a conſiderable advantage; but then probably this downineſs makes them retain moiſture upon the ear much longer than the ſmooth-chaffed varieties, and perhaps renders them more liable to be affected by thoſe diſeaſes which give a duſky colour to the chaff, and a ruſty canker to the ſtraw. The downy-chaffed varieties therefore are moſt proper for windy open ſituations; and the ſmooth-chaffed to well-ſheltered incloſed diſtricts[b].

47. Yellow Kent. See Kentiſh yellow, n. 23. 4.
48. Yeograve. See Tr. turgidum, n. 4.
49. Zealand. Straw long and reedy. Ears long and large. Spiculæ very wide ſet, nine in three inches and three quarters. Chaff white, ſometimes with a tinge of brown, opening and ſhewing the grain; which is white and full-bodied. This ſort is well adapted to weak and middling land. In a rich ſoil, eſpecially in a moiſt ſeaſon, it runs too much to ſtraw[i].

Some of theſe varieties are probably the ſame under different names, and others are different under the ſame name, in counties remote from each other. New varieties are alſo continually ariſing, and ſuperſeding old ones, ſometimes from mere faſhion, ſometimes from real ſuperiority. Varieties that are excellent in themſelves, may gradually loſe all their merit, by being cultivated in a ſoil not adapted to them, or treated in an improper manner. See an inſtance of this under n. 23. 3.

The common mode of keeping Wheat to its ſtandard, is by transferring the beſt eſtabliſhed varieties from one ſoil and ſituation to another, but this is often done without much judgment; and the farmer when he has procured at ſome expenſe a wheat ſtrongly recommended, cannot be certain that it will ſuit his ſoil. A better method would be, to ſelect from his beſt crop ſuch individual plants as excel in vigour, productiveneſs, and ſuch good qualities as are beſt ſuited to his purpoſe. Such would be more likely to be adapted to his ſoil and ſituation, than ſeed procured at a venture from other places.

But this requires attention and forecaſt, and is attended with ſome expenſe and trouble. It is difficult to preſerve a ſmall patch of corn from the birds, in a garden or near the houſe. The beſt way to ſecure it is in the middle of another crop. But with other ſorts of wheat it may be liable to take a tincture from them. Mr. Marſhall treats this apprehenſion as groundleſs; but it will require repeated experiments to convince us of what is ſo contrary to all theory. See Rural Economy of Yorkſhire, vol. 2. p. 4—9.

The uſes of Wheat are ſo obvious and generally known, that it would be impertinent to ſpeak of them. The ſtraw ſerves for various purpoſes, beſides the common ones of thatch, fodder and litter; as for making boxes, baſkets and all kinds of Dunſtable work, beehives, hats, mattraſſes, horſe-collars; for the package of goods, covering bricks, fruits, &c. from froſt, mixed with loam for walls, lighting fires, drying malt, making pot-aſh, &c.

3. Linneus's account of the many-ſpiked Wheat is, that it is allied to the ſummer or ſpring Wheat, but that the ſpike is four times as large and a hand in length, formed of ſpikelets in two rows, alternate approximating from nine to twelve, the lower ones ſhorter, but the upper one ſingle. Chaffs ſmooth, keeled. Awns a hand in length[k].

Villars remarks, that it is eaſily diſtinguiſhed by the branching of the ſpike at the baſe; and that the grains are round, and more cloſely ſet than in common wheat. Haller adds, that the calyx is hirſute and commonly three-flowered, the outer glume having an awn two inches long, the inner none: the two petals or inner chaffs lanceolate and ſomewhat hairy: the grain hairy.

It is ſaid to be a native of Egypt, at leaſt it is cultivated there, as it is alſo about Naples, in other parts of Italy, and in the South of France.

The quality of the grain is tender and delicate, it is fit therefore for paſtry, being very white, fine, and leſs ſuſceptible of fermentation. Its produce is very great; but it requires warmth, a good ſoil, and plenty of manure. It has been long cultivated in the South of Italy[l]; but it ſeems too tender for Engliſh growth. It has been cultivated in Eſſex.]

4. This is called Gray Wheat, Duckbill Wheat and Gray Pollard, in Suſſex Fuller's Wheat; [in other places Bearded Wheat, Dunover, Rivets, Pole or Poll-rivet, red Poll-rivet, Square-gray, Pendulum, Yeograve, &c.] It grows very tall, and if it is ſown too thick, is very apt to lodge with rain and wind, for the ears are large and heavy, and nod on one ſide as the grain increaſes in weight. The awns are long, and the chaff, being hairy, detains the moiſture, which helps to lodge it, for which reaſon many perſons do not chooſe to cultivate this ſort; but where the roots are at a proper diſtance, they will put out many ſtalks, which will be ſtronger, and ſupport themſelves better; the grain produces more flour in proportion than any of the other ſorts. The awns always drop off when the grain is full grown: [hence probably Haller's miſtake, in making two varieties of this Wheat, with and without awns.

This ſpecies differs eſſentially from all the preceding. The ſtraw is thicker and ſtronger, though the ſpike commonly hangs down: this is large, ſquare, villoſe, well furniſhed with grains, from two to three inches in length, often barren at the baſe, and thicker at the end. The ſpikelets have each four flowers, one of which is barren. The corolla is almoſt as long again as the calyx, villoſe as that is, often gaping at the top ſo as to ſhow the grain; the outer valve or chaff has two nerves, and is terminated by an awn, which is often three inches in length; it is not ſenſibly membranous at the edge: the inner valve is flat and lanceolate. The grain is ſhorter and more rounded than Lammas wheat, whiter, more tender, and ſcored at the baſe. It is called in French *Bled barbu*, *Bled d'abondance*, or *Moutin blanc*[m].

Of Bearded or Gray Wheat, or Rivets, there are two principal varieties, white and brown; they are ſown chiefly on wet cold lands. They ripen late in the ſeaſon, and are ſo very coarſe and ſteely, as to be unfit for making bread, unleſs mixed with a large proportion of a better ſort of flour. But they produce very abundant crops on ſtrong lands, and are ſaleable at inferior prices. They are convenient for ſowing near hedges, where birds abound. The hanging of the ear ſeems to me a proviſion for guarding it againſt the ill effects of too much wet, to which the heavineſs of the chaff would otherwiſe ſubject it.

β. Mr. Miller conſiders the Cone Wheat as ſpecifically different from the Gray Pollard.] The ears are formed like a cone, ending with a ſlender point, whence the name. The white and red Cone are mere varieties, being generally mixed in the ſame field. The awns of this are long and rough like the other, and guard

[b] Northumb. ſurvey, 66. [i] Marſh. Yorkſh. 2. 3. Northumb. ſurvey, 65.

[k] Suppl. [l] Villars. [m] Ibid.

the

the grain from birds, which recommends its being ſown in ſmall incloſures and by hedge ſides. Mr. Tull prefers this ſort for ſowing in drills; but the Gray Pollard, in Mr. Miller's opinion, anſwers much better in the horſe-hoeing huſbandry.

[Mortimer ſays that Pole-rivet or bearded Wheat is much ſown in Eſſex and Hertfordſhire upon ſtiff yellow clays: that in Oxfordſhire they reckon the long-Cone Wheat beſt for rank clays, and its ſtraw not being hollow makes it not ſubject to lodge or to be mildewed; but that the flour is ſomewhat coarſe: and that in Berkſhire they have a ſort called Pendulum Wheat, from its hanging the ear like Cone-wheat.

One hundred and thirty five buſhels of Cone Wheat were obtained from an acre and quarter of land, weighing 70 pounds to the buſhel, in the county of Lancaſter, though one fifth of the field was foul with weeds [n].

Mr. Marſhall ſays that he met with the true Cone, or Tr. quadratum of Miller in North Wiltſhire; that the baſe of the ear is large and ſquare, whence it is there called Square-eared Wheat, but that the upper part is conical, tapering to a point: that it is remarkably turgid, and the grains in the baſe of the ear, burſting open the chaff before harveſt, ſhow themſelves plainly to the eye.

The Wheat in common cultivation in the vale of Gloceſter is called Blue Cone. The ſtraw tall and reedy; the ear long and of a duſky purple colour, not conical but remarkably cylindrical; the chaff downy, with a very long awn, which falls off when fully ripe; the grain brown, tolerably well ſkinned, and of a hard flinty contexture, affording a thirſty flour, in good eſteem with the miller and baker. Three fourths of the crop in the vale is of the blue Cone [o].

Some Cone is grown on the Cotſwold hills, but not ſo much as in the vale. A new variety has lately been raiſed from the circumſtance of finding one particular grain in a parcel of ſeed: the body is remarkably long and large; but the quality, as yet, is not good, or at leaſt not ſightly [p].

Villars has a ſpecies which he names *Triticum maximum*, Gros bled, Groſſien, or Regagnon. It ſeems to belong to the Cone-wheats, though he ſuſpects it to be the ſame with Tr. polonicum of Linneus. It grows to the height of ſix feet, is ſtronger and ſtouter than any other ſort; the ſpike is from four to ſix inches long, very thick, and aſh-coloured though ſmooth. The calyx has an oblique keel, two nerves without, and a ſhort point: the glumes or chaffs of the corolla are longer; the two outer terminated by a large awn, four or five inches long; they are aſh-coloured, and a little nerved at the end; the two middle ones end in a ſhort point inſtead of an awn: the grain is long, and a little villoſe at the lower part. It is very productive, but the flour is leſs white and delicate: the grain is of a dark brown or livid colour, and abounds more in bran than meal.

γ. Barbary Wheat is made a diſtinct ſpecies by Desfontaines, but whether it belongs to this ſpecies or the ſecond I am not certain. He deſcribes it as having the ſtraw not hollow, but full of pith, long and villoſe, 30, 40 or more from the ſame root; the awns very long; the grains longer than in ſpring or winter wheat, the ſubſtance of it horny, with ſcarce any meal.

In the ſamples that I have ſeen from Barbary, the grain was plump, bright and fair to the eye, and of a deep red colour, but when cut through, there was only a ſpeck of white in the middle, the reſt being horny.

Mons. l'Abbé Poiret ſays that the grain of Wheat along the coaſt of Barbary and part of the Levant is hard, and almoſt of the ſame ſubſtance with Rice; that the little meal there is in the middle, though very white, produces a black heavy bread, difficult of digeſtion, they only uſe therefore the hard or horny part, which they reduce almoſt to the fineneſs of meal, when they would make bread, but when the Arabs prepare it for making their common diſh called *Courcouſon*, they only break it groſsly between two portable ſtones. This the Moors put into an earthen pan pierced with ſmall holes, and place it as a cover to the pot in which their meat is boiling; ſo that it is dreſſed by ſteam: it is eaten with a little broth, milk, butter, or honey [q].

δ. According to Linneus, the ſpike is larger, and aſh-coloured, and the glumes twice as long as in the preceding ſpecies; the calyxes have two flowers only, with a very long awn to each.—Haller ſays, that the ſpikelets are either three-flowered with one barren, or four-flowered with two barren.]

The Polonian Wheat grows tall, and the ears are long and heavy, ſo that where it is ſown too thick it is very ſubject to be lodged, on which account it is little regarded; but ſince it produces much flour it is worthy of cultivation.

Mr. Bobart ſays he received it from Worceſterſhire, where it is cultivated in the fields.

ε. Spelt has a ſtout ſtraw that is almoſt ſolid. Spikes ſtrong, white. Spikelets compoſed each of four flowers, of which the two lateral ones are fertile and have a long rough awn, but the two middle ones are barren and awnleſs. The chaff adheres ſo cloſe as not to be ſeparated without great difficulty [r].

Haller adds, that not only two out of the four flowers in each ſpikelet, but the lower ſpikelets alſo are entirely barren; that the flowers are more conical than in common wheat; that the chaffs of the calyx are cartilaginous, marked with lines, equal and awnleſs; that the outer floral chaff is a little longer, acuminate, putting forth an awn below the tip, in the lower flowers ſcarcely more than a line in length, but in the upper ones an inch long, the inner chaff acuminate and awnleſs, both are folded together; grain villoſe, leſs than that of common wheat.

Spelt is much cultivated in many of the ſouthern countries of Europe. In the ſouth of France they call it Epéaute blanche, and ſow it in ſpring; it ripens in july and auguſt; it requires ſtrong land, and they eſteem it to be very uſeful in deſtroying weeds, to which the ſtoutneſs of the ſtraw is well adapted [s].

Haller informs us that Spelt is the principal wheat crop in the flatter and more northern part of Switzerland, and that it is cultivated in ſeveral parts of Germany.—It is alſo very common in Arragon and Catalonia. In Spain they ſow it in ſeptember or october, and it ripens earlier than any other corn; for which reaſon it is of great uſe to the poor, although it is a light grain, yields but little flour, and the bread made from it is indifferent. The Spaniards, when in want of barley for their horſes, give them Spelt. The Swiſs employ it much for making flummery, of which the peaſants in that country are very fond [t]. Haller ſays that the flour is much whiter than that of common wheat, and contains a larger portion of the glutinous part, in which the nutritious quality reſides; but that bread made of it is drier, and very harſh when it is ſtale: he recommends it as ſuperior to any other in paſtry and confectionary.

Spelt is ſuppoſed to be the Zea of the Greeks, and the Far of the Romans. Herodotus ſays that the Egyptians uſed only the Olyra or Zea. Far was the food of the ancient Italians, and was uſed in ſacrifices [u].

Villars ſays, that Forſkahl remarked a variety of the Spelt in Egypt, the chaff of which is villoſe, and an inch and half long.

ζ. The ſpike of this is ſmaller and thinner than that of common wheat, and is ſhining; it has only one row of grains; the root tillers much, for which reaſon it is ſown thin; the worſt ſoil will do for it, if it is not too wet. The leaves that it puts forth in autumn, are more like thoſe of a weak graſs than of wheat; but all this time the root is gaining ſtrength, and in the ſpring puſhes up from 25 to 30 ſtems, which are ſo ſtrong and hard that no animal will touch them [x].

Digitized by Google

Spike diſtich, cloſely imbricate, compreſſed a little, ſomewhat ancipital. Spikelets of three or four flowers, one of which only is fertile and has a very long awn; the others are barren and awnleſs, or the awn is very ſhort. Grain ovate, acuminate at both ends, three-ſided-compreſſed, on one ſide grooved, of a pale reddiſh colour. When it germinates, it ſpeedily puts forth five radicles, like Spring Wheat[y].

This one-grained Wheat is ſown in autumn, before the common ſort, and yet ripens later; it is therefore longer in the ground than any other, and continues a whole year, or even more in the mountains. It is leſs ſubject to ſmut than common Wheat. The ſtraw is excellent for thatching. The flour is uſed for the ſame purpoſes as Spelt; but is of a better quality: the bread made of it is light, though brown; but its great excellence is for gruel[z]. Haller ſays, it is cultivated very commonly in the mountainous parts of Switzerland, even the moſt barren.—It was in the Oxford botanic garden in 1658.

Wheat Graſſes.

8. This is an annual graſs ſcarcely a ſpan in height. Flowers in a ſpike with capillary awns. Spikelets ſix-flowered. Leaves awl-ſhaped, with ſtriated ſheaths. Native of Spain[a].

9. This alſo is an annual graſs. When the Spike is ripe it falls entire and germinates, puſhing forth as many ſtems as there are ſpikelets. The ſpike itſelf performs the office of a root. The ſpikelets are many-flowered. Native of the Caſpian deſerts, in the drieſt ſoil. Introduced into the Kew garden in 1780, by Mons. Thouin.

10. This is a ſmall annual ſpecies, the length of a finger, with the uppermoſt ſheath ventricoſe. Spike hard, compreſſed, ſomewhat awned. Native of Siberia[b].

11. Root perennial, creeping. The whole plant very glaucous; the lower part of the ſtem however is of a more or leſs vivid violet hue and very ſmooth and ſhining. Leaves rigid and ſharply pungent, perfectly ſmooth at the back; their upper ſide marked with numerous longitudinal rough furrows. Stipula very ſhort. Spike ſolitary, erect, ſtraight and ſtiff, much broader in proportion to its length than that of any other Britiſh Triticum, and conſiſting of numerous alternate flat ſpikelets, of five or ſix florets each, perfectly ſmooth and beardleſs. The glumes are furrowed and blunt; the interior valve of the corolla flat and fringed.

Native of Europe, the Levant, Siberia and Barbary, on the looſe ſand of the ſea coaſt, which its long tough creeping roots, throwing out numerous woolly fibres, help to confine and keep ſtationary; to which purpoſe this graſs cooperates with Carex arenaria, Elymus arenarius, and Feſtuca rubra. It flowers in july.

The two varieties (n. 5. and 6. of Ray's ſynopſis) prove, by original ſpecimens, to differ very little from this. A maritime variety of *Tr. repens* γ is often taken for this; and ſome have taken this ſpecies, others that variety for *Elymus arenarius*[c].

12. Native of the Cape of Good Hope, where it was found by Thunberg.

13. Root perennial, creeping very much, jointed; coated; fibres downy. Stems ſlender, upright, two feet high, and double that height, when drawn up in hedges, round, ſmooth, ſtriated, having five or ſix joints, which are frequently tinged with red. Leaves ſpreading very much, flat, from five to nine inches long, and three or four lines broad, the lower ſurface ſmooth, the upper and the margin rugged; they are often all directed to one ſide. Sheaths tight, ribbed, ſmooth, terminated by a very ſhort ſtipule. Spike or ear nearly upright, two or three inches long (or more), flat, compoſed of numerous ſpikelets, with all the glumes ſharp-pointed, and often more or leſs bearded. The rachis or common ſpike-ſtalk is ſometimes hairy. The inner glumes are ciliate. The

[y] Gærtner. [z] Villars. [a] Linn. mant. [b] Linn. ſuppl. [c] Engl. bot.

number of florets in a ſpikelet varies from two to four, five, ſix, and even eight. The ſpike is much more ſlender than in *Tr. junceum*, and the ſpikelets are only half the ſize of thoſe[d].

This graſs is very common in moſt parts of Europe, Siberia, &c. and is the peſt of arable land, and particularly of gardens. It flowers from june to ſeptember, and inſinuates its long creeping roots ſo deeply into the earth as to be with great difficulty extirpated; for a very ſmall piece of the root left behind ſoon ſprouts forth into a freſh crop[e]. Beſides this the ends are ſo hard and ſharp, that they will penetrate through the moſt obdurate ſoil, and in ſtiff land are locked up ſo cloſe in the clods, that in ſome ſeaſons it is very difficult to clear the land of them.

This troubleſome and pernicious weed is too well known to farmers and gardeners, under the names of Quich, Quitch, Squitch, Twitch, Couch and Scutch-graſs, all evidently corrupted from *Quick*, which ſignifies living, and is a term well appropriated to this graſs, becauſe every particle of the root will grow. In Scotland and the north of England, it has the appellation of Quickens. Gerarde calls it, Quitch graſs, and Dogs graſs. In ſome countries it is called Spear-graſs, Dog's-graſs and Knot-graſs.—It muſt be obſerved, that farmers call any perennial graſs with creeping roots, that infeſts arable land, by this name.

This peſt of the huſbandman and gardener is not however without its uſe. At Naples the roots are collected in large quantities, and ſold in the markets to feed horſes; they have a ſweet taſte, ſomething approaching to that of liquorice. When dried and ground to meal they have been made into bread in years of ſcarcity. The juice of them drank liberally is recommended by Boerhaave in obſtructions of the viſcera, particularly in caſes of ſchirrhous liver and jaundice. Cattle are frequently found to have ſchirrhous livers in winter, and to be cured ſoon when turned out to graſs in the ſpring. It is well known that dogs eat the leaves to excite vomiting. Horſes eat them when young, but leave them when fully grown. Cows, ſheep, and goats eat them[f]. Mr. Miller affirms that the blade is ſo rough, that cattle will not feed upon it.

Six pounds of the freſh roots cut and bruiſed, and maſhed with boiling water, fermented with four ounces of yeaſt, and diſtilled, produced four ounces of liquor as ſtrong as common malt ſpirit, but of a much more agreeable flavour. From three ounces of the expreſſed juice, two drams 33 grains of chryſtallized ſaccharine acid were obtained[g].

β. The variety figured in Flora danica and Flora ruſtica has awns from two to four lines in length, and the calyxes contain from four to ſix flowers[h].

γ. A glaucous variety common on the coaſt, is often miſtaken for *Tr. junceum*, and was the *Elymus arenarius* of Mr. Hudſon's firſt edition of his Flora. [i] The leaves are ſtiff and ſharp: the calyx from three to eight-flowered, and the florets pointed[k].

14. Root perennial, fibrous, tomentoſe, not creeping. Culms very many, erect, ſtrict, two feet high, leafy, round, very ſmooth, minutely ſtriated. Leaves from upright ſpreading, linear-lanceolate, acute, nerved, rough on both ſides, ſometimes hirſute. Sheaths ſtriated, ſmooth. Stipule indiſtinct. Spike three or four inches long, nearly erect, finally nodding; looſiſh. Lower ſpikelets often in pairs, but the reſt alternate. Calyx-glumes equal, lanceolate, ſhortly awned, three or five-nerved, oppoſite, not as in Elymus and Hordeum lateral. Florets lanceolate, nerved, awned; awns twice as long as the glume, ſtraight. Inner glumes ciliate *.

15. Culm a ſpan high and ſomewhat branched. Leaves the length of the culm, with purpliſh ſheaths. Spike branched, almoſt panicled; the branches angular, ſpikelets eight or ten-flowered, alternate, compreſſed, thickeſt at the baſe, ſeſſile, ſo that they are even ſolitary on the ramifications[l].

TRI

This graſs forms tufts compoſed of bundles of ſtiff hard aſh-coloured involuted leaves, whence ariſe culms often branched at bottom, and terminated by hard aſh-coloured ſpikes, branched into panicles at their lower part; ſpikelets hard, a little compreſſed, compoſed of three or four, ſeldom five florets, intermediate in ſize between *Tr. junceum* and *tenellum* [a].—*Feſtuca dichotoma* of Forſkahl is only a younger plant of this growing in a poorer ſoil. Vahl gathered ſimilar ſpecimens in Barbary [o]. Native of France, Spain, Barbary and Egypt, but not of England.

16. Root annual. Culm a ſpan high, tender, filiform. Leaves rolled in. The ſpikes have from four to ſeven flowers, which are alternate [p].

Height from three to ſix inches. Culms hard, ſolid, ſtraight, two or three, commonly branched at the baſe, terminating in a ſpike, which is half the length of the ſtem, and compoſed of oval, ſeſſile, diſtinct, alternate ſpikelets, leaving a ſpace between each nearly equal to their length. Calyx much pointed. Outer chaff ſmooth, cylindrical, obtuſe: inner flat, very ſlightly ciliate at the ſides, bifid at the end [q]. Native of France, Spain, Italy and Switzerland.—Introduced in 1781, by Monſ. Thouin [r].

17. Root annual, capillary, villoſe. Culms many, erect, firm, round, ſtriated, naked at top and thickened. Leaves ſmooth, ſhorter than the culm. Sheaths terminated by a white membrane (ſtipule or ligule.) Rachis ſimple, flexuoſe, ſtriated, alternately excavated. Spikelets in a double row, ſeſſile, alternate, very ſmooth, flat, ovate-lanceolate, ſharpiſh, rigid, cloſely imbricate, from twelve to twenty-flowered. Outer glume keeled, ſharpiſh, inner ſmaller [s].

Desfontaines makes this graſs a Poa, following Jacquin, who had at firſt, in his Obſervations, conſidered it as a Cynoſurus. Scopoli deſcribes it as a Briza.

Vahl could not diſcover the white ſtreaks on the culm, mentioned by Scopoli, but remarks that it is ſometimes purple towards the top. He thinks it better to aſſociate it with the Triticums, on account of its toothed rachis, eſpecially as it ſeems to be allied to Tr. maritimum.

Native of Italy, Sicily, and Barbary.—Cultivated in 1758, by Mr. Miller. It flowers from july to ſeptember [t].

18. Root annual, conſiſting of long downy fibres, as in moſt graſſes that grow in pure ſand. Culms ſeveral, curved, branched, rigid, ſomewhat compreſſed, ſmooth, three or four inches high, clothed with ſheathing leaves, which are linear-lanceolate, ſharpiſh, ſomewhat rugged at the back, flat but involute when dry. Sheaths a little inflated, ſomewhat ſtriated, ſmooth. Stipule ſhort, obtuſe, eroſe. Spike erect, rigid, compoſed of from eight or nine to twelve or fifteen erect flowers or ſpikelets, placed alternately on each edge of the common rachis, but all directed to one of its flat ſides, which is thus completely hidden, whilſt the other is viſible behind. The ſpikelets are commonly ſolitary, but the lower ones are often in pairs, ſometimes three or even four together. Calyx-glumes lanceolate, equal, obtuſe, keeled, obſcurely nerved, reaching to the top of the loweſt florets: inner ones ciliate. Partial rachis flexuoſe, and exactly like the general one; an argument for the propriety of conſidering the latter as a part of the fructification, and conſequently making the plant a *Triticum*, not a *Poa*. The outer valves of the florets are very blunt, with a ſharp point; the inner are lanceolate and acute. Nectary a minute concave ſcale. Stamens and piſtils ſhort. In the habit and ſtructure of the flowers this graſs is nearly allied to Poa rigida, and it is perhaps of the ſame natural genus with it. It varies in expoſed ſituations, of a duſky violet colour [u].

Floral leaf ſhorter than the ſpike, which is from an inch and quarter to two inches long, and a quarter of an inch in breadth. Spikelets ten to fifteen, not crouded. Calyx ſix or eight-flowered; both that and the corolla awnleſs. The ſerpentine ſpike-ſtalk has a ſtrong wood-like midrib, edged with a thinner and greener border, the ſame as in Poa rigida [x].

Native of England, in many parts on the ſandy beach, as on the north coaſt of Norfolk, at Loweſtoft in Suffolk, near South End Eſſex, near Wiſbeach in Cambridgeſhire, and in the Iſle of Wight; flowering about Midſummer.—It is alſo native of Dauphiné, according to Villars, who remarks that this ſpecies, diſcovered by the ſagacity of Ray and Scheuchzer, ſeems to have been forgotten by modern botaniſts. The ſingle culms, he ſays, are only two or three inches long, and the ſpike occupies the upper third of them; the leaves are tender, ſtriated and very narrow; the lower ſpikelets are on a filiform peduncle about a line in length, the upper ones are ſeſſile; the former are inſulated, the latter are ſo cloſe that there are ten or twelve in the ſpace of an inch; they are very ſmall, having three, four or five filiform florets in a very narrow calyx; the chaffs are ſo pointed that they ſeem to have an awn, as in Scheuchzer's figure; but viewed in a magnifying glaſs, they are ſmooth, cylindrical and awnleſs.

19. Height three or four inches, of which the ſpike occupies half; it is thin and turned on one ſide, compoſed of ſeſſile ſpikelets, which are very cloſe to each other, each containing four or five flowers, the lower ones awnleſs, the upper having ſhort terminating awns, annual.

Scheuchzer and Linneus have not remarked any awns upon the chaffs of this graſs; but as they are very ſhort, and on the upper flowers only, they might not perceive them, or perhaps they are not always preſent. It is however too well characterized to be miſtaken. It differs from the *unilaterale*, not only becauſe in that the partial ſpikes are turned on one ſide, but the leaves are wider and not ſo hard, and the ſpike as little again as the glumes, more diſtinct, leſs in number, terminated by a point or awn which is always viſible. Moriſon's figure referred to under *Tr. tenellum* rather belongs to this ſpecies [y]. Dr. Smith ſays, that Moriſon's is a good figure of the unilaterale. Native of the South of France and Italy, on the ſea coaſt.

PROPAGATION AND CULTURE.

1. To aſcertain that Spring Wheat is really diſtinct from Lammas Wheat, Mr. Macro ſowed them on the ſame piece of land in april. Whilſt the latter was tillering, the former ran up to ear, and produced a good crop; whereas not more than a tenth part of the other, which was red Kentiſh wheat, eared at all, and not a ſingle grain came to perfection [z].

Thomas Ruggles, Eſq. an experienced agriculturiſt, as well as elegant ſcholar, made ſome experiments in his farm at Clare in Suffolk, in 1785 and the two following years on the comparative produce of Spring Wheat, with Winter Wheat and Barley. His concluſion is, that Spring Wheat is more likely to anſwer the wiſhes of the farmer in the South than in the North of Europe; and that it makes a better figure in Columella, than in the Annals of Agriculture [a]. The detail of his experiments are well worth peruſal.

Dr. Wilkinſon has tried Spring Wheat at Enfield Chaſe for ſeveral years, and in 1799 ſowed it ſo late as the 10th of may, yet it was ripe before barley ſown at the ſame time in the ſame field. It ſhould never be ſown earlier than april, for it is too tender to ſuſtain much froſt. He has grown three quarters, but the average produce with him has been two quarters to the acre [b].

Mr. Marſhall informs us, that Spring Wheat has been ſufficiently tried in Yorkſhire to aſcertain that the proper month of ſowing is april. See more in our deſcription, &c. above.]

2. The ſeaſon for ſowing of Lammas or winter Wheat is autumn, and always when the ground is moiſt. In the downs of Hampſhire, Wiltſhire, and Dorſetſhire, the farmers begin ſowing of their Wheat

in auguſt, if there happens rain; ſo that when they are in their harveſt, if the weather ſtops them, they employ their people in ſowing, for if the Corn is not forward in autumn, ſo as to cover the ground before winter, it ſeldom ſucceeds well on thoſe dry lands, eſpecially if the ſpring ſhould prove dry; but in the low ſtrong lands, if they get their Wheat into the ground by the middle of november, the farmers think they are in good ſeaſon; but ſometimes it ſo happens, from the badneſs of the ſeaſon, that in many places the Wheat is not ſown till Chriſtmas or after, but this late-ſown Wheat is ſubject to run too much to ſtraw, eſpecially if the ſpring ſhould prove moiſt.

The uſual allowance of ſeed Wheat to one acre of land is three buſhels, but from repeated experiments, it has been found, that leſs than half the quantity is more than ſufficient; therefore, if the farmers have regard to their own intereſt, they ſhould ſave this expence of ſeed, which amounts to a conſiderable article in large farms, eſpecially when it is to be purchaſed, which moſt of the ſkilful farmers do, at leaſt every other year, by way of change; for they find that the ſeeds continued long upon the ſame land will not ſucceed ſo well, as when they procure a change of ſeeds from a diſtant country. And the ſame is practiſed by the huſbandmen of the Low Countries, who commonly procure freſh ſeeds from Sicily every ſecond or third year; which they find ſucceed better with them, than the ſeeds of their own country. In the choice of the ſeeds, particular regard ſhould be had to the land upon which it grew, for if it is light land, the Wheat which grew upon ſtrong land is the beſt, and ſo vice verſa.

There have been ſome perſons in England curious enough to procure their ſeed Wheat from Sicily, which has ſucceeded very well, but the grain of this has proved too hard for our Engliſh mills to grind, which has occaſioned their neglecting to procure their ſeeds from thence; nor do I think there can be much advantage in procuring the ſeeds from abroad, ſince the lands of England are ſo various, as to afford as much change of ſeeds as will be neceſſary. And the leſs we purchaſe from abroad, the greater will be the ſaving to the public; ſo that it ſhould be the buſineſs of ſkilful farmers to want as few ſeeds as poſſible, ſince, by exchange with each other, they may ſo contrive, as not to part with ready money for any ſeeds. The land which is uſually allotted for Wheat, is laid fallow the ſummer before the Corn is ſown; during which time it is ploughed two or three times, to bring it into a tilth; and the oftener and better the ground is ploughed, and the more it is laboured with harrows between each ploughing to break and divide the clods, the better will be the crop, and the fewer weeds will be produced. But in this article moſt of the farmers are deficient, for after they have given their lands one ploughing, they frequently leave it to produce weeds, which ſometimes are permitted to ſtand until they ſhed their ſeeds, whereby the ground will be plentifully ſtocked with weeds; and as an excuſe for this, they ſay that theſe weeds will ſupply their ſheep with ſome feed, and the dung of the ſheep will mend their land; but this is a very bad piece of huſbandry, for the weeds will draw from the land more than the dung of the ſheep will ſupply; ſo that it is undoubtedly the beſt method to keep the ground as clean from weeds as poſſible, and to ſtir it often to ſeparate and break the clods, and render the land fine; and where the land can enjoy a winter's fallow, it will be of much greater ſervice to it than the ſummer; and by thus labouring of the land, it will be of equal ſervice to it as a dreſſing of dung. Therefore if the farmers could be prevailed on to alter their method of huſbandry, they would find their advantage in it; for the expence of dreſſing in ſome counties is ſo great, as to take away the whole profit of the crop.

There is alſo a very abſurd method in common practice with the farmers, which is the carrying out of their dreſſing, and ſpreading it on the land in the ſummer, where it lies expoſed till the ſun has dried out all the goodneſs of it, before it is ploughed into the ground ſo that the dreſſing is of little value; therefore the dung ſhould never be laid on the land faſter than it can be ploughed in, for one load of dung ſo managed, is better than three in their uſual method.

As Wheat remains a longer time upon the ground than moſt other ſorts of Corn, it requires a greater ſtock of nouriſhment to lengthen and fill the ears: therefore, if the dreſſing is exhauſted in winter, the Corn will have but ſhort ears, and thoſe but lean, nor will the grain afford much flour; ſo that it frequently happens, that a light dreſſing of ſoot in the ſpring, at the time the Wheat is beginning to ſtalk, proves of greater ſervice to the crop, than a dreſſing of dung laid on the land before it is ploughed, eſpecially if the dung is not very good. Deep ploughing (where the ſtaple of the ground is deep enough to admit of it) will alſo be of great ſervice to the Corn, for the ſmall fibres of the roots, which are the mouths that ſupply the nouriſhment, extend themſelves very deep into the ground. I have traced many of them upward of three feet, and believe they ſpread much farther where the ground is light; therefore it is of great advantage to the crop to have the ground ſtirred and looſened to a proper depth, for by ſo doing the roots will find a ſupply of paſture for the nouriſhment and augmentation of the ears, at the time they are forming, when it is moſt required; for if the ground is ploughed ſhallow, the roots will have extended themſelves to that depth by the ſpring, ſo that when the nouriſhment is wanted to ſupply the ſtalks, the roots are ſtinted by the hardneſs of the ſoil, which they cannot penetrate; when this is the caſe, the colour of the blade is frequently ſeen to change in april, and ſeldom recovers its verdure again; and when this happens, the ſtalks are always weakened in proportion to the decay of the blade; for it is well known from long experience, that the leaves or blade of Corn, are neceſſary to draw in nouriſhment from the air and dews, for the increaſe of the ſtalk and ear; but in order to aſcertain this, I have made trial of it, by cutting off the leaves of ſome roots of Wheat alternately, early in the ſpring, and have conſtantly found the ſtalks upon thoſe roots much ſmaller, the ears ſhorter, and the grain thinner than thoſe of the intermediate roots, whoſe blades were not cut. This ſhews the abſurdity of that practice of feeding ſheep upon Corn in the winter and ſpring. I have frequently ſeen in ſome gardens, plants diveſted of their lower leaves, which ignorant perſons have ſuppoſed to draw away the nouriſhment from the head; but wherever this has been practiſed, I have always ſeen the plants have been greatly weakened by it; ſo that until thoſe leaves decay naturally, they ſhould never be taken off.

Of late years, many compoſts have been advertiſed for the ſteeping of the ſeeds of Corn, in order to improve their growth, ſome of which have been ſold at a dear rate; but as ſo great ſucceſs was aſſured by the inventors to thoſe who ſhould make uſe of them, there were numbers of perſons who made the trial; but ſo far as I have been able to get information of their experiments, they did not ſucceed ſo well as to encourage the uſe of theſe compoſitions; and from ſeveral trials which I made myſelf with great care, I always found, that the Wheat which had been ſteeped in theſe compoſitions came up ſooner, and grew much ranker in the winter, than that which had not been ſteeped; but in the ſpring the unſteeped Wheat had a greater number of ſtalks to each plant, and the ears were better fed than thoſe which had been ſteeped; therefore theſe ſorts of compoſts have been found of no real uſe to the crop.

My experiments were made in the following manner. The Wheat was ſown in drills, on the ſame ſpot of ground; the ſeeds that had been ſteeped were ſown in alternate rows, and the intermediate rows were ſown with unſteeped Corn. The rows were a foot and a half aſunder, and the grains were all taken out of one meaſure, and ſown as equally as poſſible: the ſteeped Corn appeared above ground three days before

Digitized by Google

fore the other, and continued to grow faſter than the unſteeped Corn during the winter, but in the ſpring the blade of the ſteeped Corn changed its colour, and their points became of a brown colour, when I gave a light dreſſing to one of the rows, which ſoon recovered its verdure, and cauſed it to be the ſtrongeſt row of the whole; but the others which had not this dreſſing, produced weaker ſtalks and ears than that which was not ſteeped.

I have before obſerved, that in general the farmers ſow more than double the quantity of Corn on their lands than is neceſſary; therefore there is a great waſte of grain, which in ſcarce years amounts to a conſiderable ſum in large farms, and to a whole country it is an object worthy the attention of the public: but I fear whatever may be ſaid to prevent this, will have but little weight with the practitioners of agriculture, who are ſo fond of old cuſtoms, as rarely to be prevailed upon to alter them, though they are extremely abſurd. But if theſe people could be prevailed on to make the trial with care, they muſt be ſoon convinced of their error; for if they would but examine a field of Corn ſown in the common way, they will find but few roots which have more than two or three ſtalks, unleſs by chance, where there may be ſome few roots which have room to ſpread, upon which there may be ſix, eight, or ten ſtalks, and frequently many more; but in a field of Wheat which had not a greater allowance than one buſhel of Corn to an acre, ſo that the roots had room to ſpread, I have obſerved the roots produced from ſix to twelve, or fourteen ſtalks, which were ſtrong, and had long well nouriſhed ears, and the produce was much greater than in any of thoſe fields in the neighbourhood, which were ſown with the common allowance. And if the land is good, and the roots ſtand at a proper diſtance from each other, there will be few roots which will not produce as many ſtalks as I have here mentioned, and the ears will be better nouriſhed.

But if the land is not covered with the blades of Corn by the ſpring, the farmers think they ſhall have no crop; whereas, if they would have patience to wait till the roots put out their ſtems, they would ſoon be convinced of the contrary; eſpecially if they could be prevailed on to draw a weighty roller over the Wheat in march, which will cauſe it to ſpread; and by ſettling of the looſe ground to the roots, the drying winds in the ſpring would be prevented from penetrating to their fibres, ſo that the roots will produce the more ſtalks; but before this operation, it will be proper to have the Corn cleaned from weeds; if theſe are permitted to grow, they will draw away much nouriſhment from the Corn; and if, at this ſeaſon, the land is made clean from weeds, the Corn will ſoon after ſpread and cover the ground, whereby the growth of weeds will be greatly leſſened.

There is not any part of huſbandry which requires the farmer's attention more, than that of keeping his land clean from weeds; and yet there are few who trouble themſelves about it, or who underſtand the proper method of doing it; few of them know thoſe weeds which are annual, ſo as to diſtinguiſh them from thoſe which are perennial; and without this knowledge, it will be much more difficult for a perſon to clean his land, let his induſtry be ever ſo great, for annual weeds may be ſoon deſtroyed if taken in time; whereas, if they are neglected, their ſeeds will ſoon ripen and ſcatter; after which it will require three times the labour and expence to get rid of them, as would have been ſufficient at the beginning, and then the crop would have had no bad neighbours to rob it of its nouriſhment. The common method now practiſed is a very abſurd one, for the weeds are left to grow till the Wheat is beginning to ear, and the weeds are in flower; ſo the ground being covered by the Corn, all the low weeds are hid, and theſe are left to ripen and ſcatter their ſeeds; the tall weeds only are taken out, and if the people employed are not careful, many of theſe will eſcape them, as they will be ſo intermixed with the ſtalks of Wheat as not to appear, unleſs diligently ſought after. By this method the weeds of tall growth are permitted to ſtand, and rob the Corn of its nouriſhment, during the principal time of its growth, and the humble weeds are never deſtroyed; and by going amongſt the ſtalks when they are tall, great numbers of them are broken and trod under the work people's feet; yet however obvious this is to every farmer, none of them have thought of altering this practice. I would therefore recommend a method which is now in common practice amongſt the kitchen gardeners, which has been found of great benefit to their crops, and has alſo been a great ſaving to them in the expence of weeding; and this is making uſe of hoes for cleaning the Wheat early in the ſpring, before the ground is covered with blades of Corn. With this inſtrument, all the low as well as the tall weeds will be cut up, and if it is performed in dry weather, the weeds being then ſmall will ſoon die. Where the ground happens to be very full of weeds, it may be neceſſary to go over it a ſecond time, at about a fortnight after the firſt, to cut up any weeds which may have before eſcaped. By laying the ground clean at this time, the Corn will not be robbed of its nouriſhment; and there will not be time for the weeds to grow ſo as to prejudice it much after, for the ground will be ſo much ſhaded by the Corn, as to keep down the weeds, ſo that they cannot have time to ripen their ſeeds before harveſt.

If, at the time of this operation, the roots of Corn are cut up where they are too cloſe, it will be found of great ſervice to the other; but this, I fear, few of the old farmers will ever agree with me in; though what I mention is not from theory but experiments, which have been repeated with great care; and where it was practiſed the produce of twenty rods of ground, was much greater both in weight and meaſure, than the ſame quantity of ground in the beſt part of the field where this was not practiſed, and the ſtalks ſtood upright, when a great part of the Corn in the ſame field was lodged.

I have often obſerved in thoſe fields where foot-paths are made through Corn-fields, that by the ſide of thoſe paths where the Corn is thin, and has been trodden down in the winter and ſpring, that the ſtalks have ſtood erect, when moſt of the Corn in the ſame field has been laid flat on the ground; which was owing to the ſtalks being ſo much ſtronger from their having more room, the other having been drawn up tall and ſlender by being ſo cloſe together. There is alſo another great advantage in keeping Corn clean from weeds, and giving it room to ſpread, which is, that the Corn is not ſo liable to take the ſmut as when it is full of weeds, and the roots too much crowded, as I have frequently obſerved; ſo that cleanneſs and free air, is as eſſential to the well doing and growth of vegetables as animals; and the changing of the ſeed annually is alſo as neceſſary, as the change of air is to all ſorts of animals; for where this has been carefully practiſed, there has rarely happened any ſmutty Corn in the field.

Brining of the ſeed Wheat is what the farmers generally practiſe to prevent the ſmut, which in moſt years anſwers very well, but there is nothing which contributes more to this, than keeping the plants in good health, which is better effected by the method before propoſed; for by ſtirring of the ground with the hoe between the roots of Corn in the ſpring, they will be better ſupplied with nouriſhment; for in ſtrong lands, where the water may have lain in the winter, the ſurface of the ground will bind ſo hard on the firſt dry weather as to ſtint the Corn, and frequently cauſe it to change colour. When this happens, the roots ſeldom put out many ſtalks, and thoſe which are put out, are weak; but where the ſurface of the ground can be ſtirred to looſen the parts, the Corn will ſoon recover its colour and ſtrength, and cover the land with ſhoots.

What has been here directed, muſt be underſtood to relate to Wheat ſown in broad-caſt, which is the uſual method practiſed by farmers in every part of England; for the horſe-hoeing huſbandry which was practiſed by Mr. Tull, has been almoſt univerſally rejected by the farmers in every country, it being ſo oppoſite to their accuſtomed practice, that they cannot be prevailed

Digitized by Google

vailed upon to make trial of it; and indeed, by the abſurdity of the author in a few particulars, he has diſcouraged many from engaging in it, who would have practiſed it; but upon finding Mr. Tull poſitively aſſerting, that the ſame land would nouriſh the ſame ſpecies of plants without changing the crops for ever, and this without manure, which being contrary to all experience, led them to believe his other principles had no better foundation. And he practiſed this method of ſowing the ſame ſpecies upon the ſame ground, till his crops failed, and were much worſe than thoſe of his neighbours who continued their old method of huſbandry, and hereby his horſe-hoeing huſbandry was ridiculed by them, and laid aſide by gentlemen who were engaging in it. But notwithſtanding theſe and ſome other particulars which have been advanced by Mr. Tull, yet it is much to be wiſhed that this new huſbandry might be univerſally practiſed; for ſome few perſons who have made ſufficient trial of it, have found their crops anſwer much better than in the common or old method of huſbandry; and the French, who have learned it from Mr. Tull's book, are engaging in the practice of it with greater ardour than thoſe of our own country: and although they had not the proper inſtruments of agriculture for the performance, and met with as ſtrong oppoſition from the perſons employed to execute the buſineſs as in England, yet the gentlemen ſeem determined to perſiſt in the practice of it, though as yet few of their experiments have had the ſucceſs they hoped for; partly from the aukwardneſs of their labourers, and partly from their averſeneſs to practiſe this huſbandry, and alſo from their being made in land not well conditioned, but yet their produce has been equal to that of the old huſbandry; and they ſay, that if the produce of the land in the new method of huſbandry does not exceed that in the old way, yet by ſaving ſeven parts from eight of the ſeed Corn, it is a great affair to a whole country, eſpecially in times of ſcarcity.

As Mr. Tull has given a full direction for the practice of this huſbandry, I ſhall refer the reader to his book for inſtruction, and ſhall only mention two or three late experiments which have been made in his method, whereby the utility of it will more fully appear.

The firſt was in a field of Wheat, which was ſown partly in broad-caſt in the common method, and partly according to Tull's method; the ſpots thus ſown were not regular in lands, but interſperſed indifferently in many directions. Thoſe parts of the field in Tull's method, were in rows at two feet diſtance, and ſtood thin in the rows. The roots of the Wheat in theſe ſpots had from ten to thirty ſtalks on a root, and continued upright till it was reaped; whereas few of the roots in the common method had more than two or three ſtalks, and theſe were moſt of them lodged before harveſt; ſo that upon trial of the grain when threſhed, there was near a third part more in weight and meaſure, than from the ſame extent of ground, taken in the beſt part of the field ſown in the common way.

Another trial was made in ſowing of the Corn in rows at different diſtances, with ſome ſown in two parts of the ground broad-caſt. The event was, that all which was ſown broad-caſt in the uſual way was lodged, as was alſo moſt of that where the rows were ſix or nine inches aſunder; thoſe which ſtood a foot diſtance eſcaped better, but the rows two feet aſunder were the beſt, and the produce much greater than any of the other; which plainly ſhews the abſurdity of that practice, in ſowing a great quantity of ſeeds to have a better produce, which is the opinion of moſt of the old farmers; and it was formerly the prevailing opinion among gardeners, who allowed near eight times the quantity of ſeeds for the ſame ſpace of ground as is now uſually ſown, and theſe crops are greatly ſuperior to any of thoſe.

The produce of an acre of Wheat is various, according to the goodneſs of the ſoil. In ſome of the ſhallow, chalky, down lands, where there have been near four buſhels of Corn ſown, I have known the produce not more than double of the ſeed; but when this is the caſe, the farmer had much better let his land lie waſte, ſince the produce will not defray the expence, ſo that more than the rent of the land is loſt: and although theſe ſorts of crops are frequently ſeen on ſuch land, yet ſuch is the paſſion for ploughing among the huſbandmen at preſent, that if they were not reſtrained by their landlords, they would introduce the plough into every field, notwithſtanding they are ſure to loſe by it.

But although the produce of theſe poor downs is ſo ſmall, as before related, yet upon good land, where the Corn has ſtood thin upon the ground, I have known eight or ten quarters reaped from an acre, over the whole field, and ſometimes much more. And I have been informed by perſons of great credit, that on good land, which was drilled and managed with the horſe-hoe, they have had twelve quarters from an acre of land, which is a great produce; and this is with greater certainty, if the ſeaſons prove bad, than can be expected by the common huſbandry.

The fineſt field of Wheat I ever yet ſaw, was ſown in rows at a foot and a half diſtance; the allowance of ſeed to this field was three gallons, and by the common practice of the farmers, there is ſeldom leſs than three buſhels, which is eight times the quantity: this Wheat was hoed by the hand twice in the ſpring, which coſt five ſhillings and ſix-pence per acre. When the Corn was in ear, it was not leſs than ſix feet high; there were from twelve to twenty ſtalks on each root, which were ſo ſtrong as to all ſtand upright; the ears were very long, the ground perfectly clean from weeds, and the produce was more than eleven quarters to an acre of land. Theſe experiments, one ſhould imagine, would excite an induſtry among farmers to the practice; but on the contrary, not one of thoſe in the neighbourhood would follow it.

[This work not profeſſing to be a complete body of Huſbandry, it is not to be expected that we ſhould enter into all the minutiæ of the culture of Wheat; and yet, as it is a ſubject of primary importance, we ſhould ſcarcely be excuſed, if we did not treat of it ſufficiently though ſuccinctly.

Preparation.

The old Preparation for Wheat is a naked ſummer fallow. If there is one practice in huſbandry, ſays Mr. Young, ſhown by modern improvements to be worſe than another, it is that of ſowing Wheat on fallows. And yet it is ſtill the practice in many places. Where they are thought neceſſary, let them be ſown with barley or oats, or any thing rather than Wheat.

In ſome counties the fallows are ploughed juſt before harveſt on to two bout ridges, ready to plough and ſow under furrow in the ſpraining method, a ſeedſman to every plough, which reverſes the ridges. In others they lay their lands into ten or twelve furrow ſtitches or lands, and ſow ſome under furrow, ſome under the harrow. Ridges vary exceedingly, according to their wetneſs; and in Kent, by means of the turn-wreſt plough, they have no ridges, but the whole field an even ſurface [c].

Other preparations for Wheat are, Beans, Clover, Lay, Peas, Potatoes, Rape, Tares and Turneps. Wheat ſhould never be ſown after Rie, Barley or Oats, nor ſhould the land be manured for it, but for the preceding crop [d].

Beans, if well cultivated, form the beſt preparation for wheat. Mr. Young ſaw in Kent a field of Wheat, which followed beans, clover, tares and fallow; the firſt was ſuperior to all the reſt, next the clover, then the tares, and the worſt was after the fallow. The bean-ſtubble ſhould have its due tillage as early as poſſible: this will depend on ſoil, for on ſome it will be more advantageous to truſt to the ſhim, ſcarifiers and ſcufflers, than to the plough. If the land be very clean, the great Iſle of Thanet ſhim will cut through every thing, and looſen the ſurface ſufficiently to enable the harrows to leave it as clean and fine as a garden; women attending to pick and burn. If leſs

[c] Calendar, 483. [d] Midd. ſurvey, 167. Young's ann. 18. 444.

Digitized by Google

clean, the Kentiſh broad-ſhare may do the work more effectually. In other caſes the ſcuffler may be equal to the buſineſs. It is now to be conſidered whether the land ſhould be ploughed or not: if the ſoil be of a firm, ſolid, tenacious quality, and it is not intended to drill, it may be adviſeable; there will then be no apprehenſion of the Wheat being root-fallen, but a new ſurface will be brought up, which will drill with difficulty. If the ſoil be of a more looſe, friable quality, and the finer ſurface gained ſhould be ploughed down, the Wheat having too looſe a bottom will run the chance of being root-fallen. In ſuch caſes, it is beſt not to plough, but drill directly; which ſaves tillage, and gives the probability of a better produce. This is new practice on ſtrong land, but there is no reaſon to doubt of its being right. Mr. Ducket purſued it on a ſandy ſoil for many years with great effect. Whatever other circumſtances may influence the growth of this grain, it loves a firm bottom to root in, and rarely flouriſhes to profit, when that is looſe and crumbly; nor muſt the under ſtratum be in its quality repellent. The beſt baſis is the cultivable earth, firm from not having been lately diſturbed [e].

Clover forms a very excellent preparation for Wheat; and while the Norfolk huſbandry of 1. Turneps. 2. Barley. 3. Clover. 4. Wheat; is practicable on a farm, dry enough for turneps, and rich enough for wheat, a farmer might be ſatisfied with his profit. But after many repetitions of this courſe it has been found, that Turneps required ample manuring, where they had not wanted any; and that Clover became ſo ſubject to failures, that it was no longer eaſy to have it every fourth year. This created the neceſſity of variations, but ſtill retaining clover as the preparation for Wheat. The huſbandry however was very imperfect, by the mode of putting in the Wheat by the harrow, when the ſeed was apt to fall into the ſeams of the furrows, and conſequently to come up among whatever graſs and weeds might be in the land. The diſcovery of dibbling was a great improvement: by this method the ſeed was depoſited in the centre of the flags, and the regular treading the land received, preſſed down the furrow, and gave a degree of firmneſs not otherwiſe attainable. The ſucceſs was great, but the labourers have done it of late years in ſo ſlovenly a manner, that drilling is every where coming in, both in Norfolk and Suffolk. At preſent, it is thought in thoſe counties the mark of a bad farmer to ſow Wheat broad-caſt on clover.

The land having been ploughed a fortnight or three weeks, it is to be well rolled down with a heavy roller, and then dibbled: the chief attention is to be paid to the dibblers making the holes deep enough, and to the children dropping equally without ſcattering. It is then buſh-harrowed. Six pecks of ſeed are ſufficient for two rows on a flag in ſeptember; but in one row as much ſhould be put in: and if the land is given to mildew, an increaſe of ſeed on that account is right, whatever be the ſoil or ſeaſon; it being well known, that thin crops ſuffer moſt from that diſtemper. For drilling, it ſhould be remembered, that in ploughing all lays, the uſe of the ſkim-coulter is very great, and in ſome caſes indiſpenſable: an effective harrowing ſhould precede the drill: the quantity of ſeed is the ſame as in dibbling [f].

Wheat is ſometimes ſown on graſs land, broken up in the ſummer, after the hay has been cut off: but on old lays it is more uſual firſt to take a crop or two of oats, according to the ſtrength of the land.

Peas are a good preparation for Wheat, on land which is too light for beans, being a good ſmothering crop.

Great crops of Wheat have been grown after potatoes, well manured for, and on a proper ſoil; but barley has been generally found to do better. See *Potatoes* under SOLANUM; art. *Crops following*.

A good crop of winter Tares leaves the ground in ſuch looſe, friable order, that it is much better huſbandry to ſow turneps or plant cabbages on it, than to leave it to receive tillage for Wheat. However if this management ſhould take place, the land ſhould not be ploughed, but left to conſolidate at bottom, for the roots of the Wheat to fix in, and the ſurface worked with the ſcarifiers or ſcufflers, according to its temper, juſt ſufficient to keep it clear of weeds, and in that ſtate, drill the Wheat without any ploughing [g].

Wheat is ſometimes ſown after Rape and Turneps; and I have ſeen Turneps ſown after Wheat; the land being ploughed whilſt the ſhocks were ſtanding in the field. It is more common to ſow Barley after Turneps.

Steeping the Seed.

It has been a great controverſy whether this operation be beneficial or not; the evidence certainly goes much in favour of doing it; and there can be no objection to it except the expence and trouble; unleſs the ſeed-Wheat be ſuffered to lie too long in ſome mixtures. The intention of them is to guard againſt the ſmut, and the modes of ſteeping, brining and liming are innumerable. Arſenic has lately had the preference; and Mr. Young informs us, that it appears from his experiments that ſteeping the ſeed from twelve to twenty-four hours in a ley of wood aſhes, in lime water, and in a ſolution of arſenic, gave clean crops from extremely ſmutty ſeed; but a ſhort time in thoſe mixtures had a much leſs effect [h].

In Northumberland, and ſome other parts, the ſeed Wheat is thrown into a veſſel full of chamberley; it is ſtirred about with a ſtrong ſtick, and the light grains are ſkimmed off; the liquor is then let off, and the Wheat taken out, and mixed with powdered quick-lime, till it is dry enough for ſowing: the ſooner this is done the better; becauſe it is apt to heat if ſuffered to continue in the ſacks, or in large heaps; but if dried and ſpread thin on a granary floor, will keep ſeveral days. Five or ten minutes are as long as the ſeed ſhould ſteep in the liquor; its vegetative powers will be injured if it remain much longer in very putrid chamberley [i].

Salt water, where the ſea is near, and brine, where it is not ſo, are the common ſteeps for ſeed Wheat in moſt places. After ſoaking for a few hours, it is taken out, and a ſufficient quantity of lime, to dry it for ſowing, is ſifted over it. This however is ſaid often to prove ineffectual: and Mr. Wyborn of Hull in Kent, whoſe Wheat one year after brining was uncommonly full of ſmut, endeavoured to inveſtigate the nature of this diſtemper, and diſcovered that it was an infectious diſeaſe, and curable by arſenic. But if the Wheat ſtands much more than ten or twelve hours in the ſolution of arſenic, vegetation will be totally deſtroyed [k].

Mr. Middleton, in his ſurvey of Middleſex, (p. 168.) ſays, he has prevented the ſmut, 'by putting lime recently burnt, into a copper of boiling water, and pouring this mixture, boiling hot, on the Wheat, previouſly ſpread on a ſtone floor, immediately turning the Wheat and the mixture well together with ſhovels. This is done over night, and the ſeed is commonly ſown the next day.

On good authority it is affirmed that the ſmut may be prevented by ſimply waſhing the ſeed Wheat in clean water, ſeveral times if neceſſary [l].

It is ſuppoſed by ſome, but ſeemingly without much reaſon, that ſteeps act as prolific liquors, to invigorate the germ; but they probably act no farther than in deſtroying the ſmut, whatever it be. They may be too weak to do this; and if they are too ſtrong, or the ſeed remain too long in them, they may injure the vegetation.

Time of ſowing.

October and november are the months in which Wheat is commonly ſown. It has been lately thought in ſome places that ſeptember is a ſtill better time, provided it be wet enough, but few farmers are ready ſo early [m].

[e] Young calendar, 459. [f] Idem, 456. See Suffolk ſurvey—47-52.

In

In Mid-Lothian it is ſown with ſucceſs from the end of auguſt, when it is common with ſeveral farmers to ſow their fallows, to the beginning of april, when turnep-land has been known to be ſown [o].

In Northumberland, the fallows are ſown in ſeptember and october; after drilled beans Wheat is ſown in october and november; and after turneps all through the winter, until the middle of march. On account of ſnow lying late, many hundred acres have been ſown in april, and produced a good crop. The experienced ſurveyors are diſpoſed to think, that on thoſe light ſoils, february is the beſt ſeed-time for Wheat, maſlin and rie [p].

Good crops have been had in the north riding of Yorkſhire, from ſowing at the beginning of april; but ſowing ſo late as this, or even at candlemas, is very precarious, for if the ſummer be wet, the corn is little worth. Upon warm turnep land, Wheat may be put in as late as Chriſtmas, with great advantage; but beyond that time, it is apt to be lean in the ear, and to be infected with ſmut [q].

In Middleſex, Wheat is ſometimes ſown after turneps in january and february, and even ſo late as the middle of march: but october is thought to be the moſt promiſing ſeaſon, and of courſe, all the land that is then ready ought to be ſown [r].

In Kent, on wet and cold lands Wheat is ſown early in october; on ſtiff and drier clay ſoils ſomewhat cold, about the middle of that month; but the general time for the county is the month of november. Sometimes it happens, by badneſs of weather, &c. that a conſiderable quantity is ſown the firſt week in december, but the more early ſowings generally produce the ſtrongeſt crops [s].

Upon all cold, wet, backward ſoils, ſeptember is the beſt ſeaſon for putting in Wheat, provided there has been rain in tolerable plenty. Upon drier and warmer ſoils it is better to poſtpone it to october. But clover and other layers ſhould be ploughed, if rain comes, in ſeptember, for it is a great advantage to have them remain unſown for three weeks of a month after ploughing [t].

In the vale of Gloceſter, the time of ſowing is november and december; and if a farmer get his ſeed into the ground before Chriſtmas, he is thought to finiſh in due ſeaſon: this country is therefore nearly a month behind the reſt of the kingdom. There are two diſadvantages attending this late ſowing: the uncertainty of the ſeaſon, and the want of a greater quantity of ſeed.

On the contrary, the Cotſwold hills are in a manner proverbial for early ſowing; auguſt and ſeptember being the principal months. The general rule is to begin ploughing in july, and to begin ſowing the firſt wet weather in auguſt. Wheatſeed time therefore generally commences in Wheat harveſt; and the farmers wiſh to ſee the ground covered before michaelmas. The diſtricts that form the two extremes, with reſpect to the time of ſowing Wheat, are included within the ſame county, and even lie contiguous to each other [u].

Mr. Young relates a ſucceſsful experiment of early ſowing, with a view to eſcape the mildew. He ſowed eight acres after tares the beginning of ſeptember, finiſhing the fifteenth. It came up in eight or nine days; the autumn proved remarkably dry; it was the eleventh of november before any rain fell, and all the farmers were ſowing at the end of november and beginning of december. In the ſpring and ſummer the early-ſown Wheat flouriſhed remarkably, while ſeven-eights of the crops around had a miſerable appearance, and ſome parts of fields were actually ploughed up. At harveſt this field was ready to cut three weeks before any other, and a month before many. Reaping was commenced on the twenty-eighth of july, and on the fourteenth of auguſt the whole was carted to the ſtack. This earlineſs of harveſt will generally be a great advantage. In reſpect to the mildew, it totally eſcaped; yet ſeveral fields near it were conſiderably attacked. The crop, though extraordinary for the ſeaſon, was not large, owing to its being ſown too thick; namely, two buſhels and a peck to the acre, whereas ſo early one buſhel and a half would have been enough. The year following he ſowed twelve acres thinner, in ſeptember, which were a very capital crop, quite bright and clean from mildew, except ſome few ſpots; it was quite ripe, and reaping on the fifteenth of auguſt [x].

Mr. Pitt of Pendeford in Staffordſhire obſerves, that very early ſowings exhauſt the land too much the firſt ſummer, and give too much time for the growth of noxious weeds; he adds, that he always remarked Wheat ſown the beginning of ſeptember new ſtyle to be much fouler the ſucceeding ſpring, than that ſown a month later on equal land.

The greateſt evil he has found to attend late ſowing on ſound land, is from vermin, eſpecially rooks and larks [y].

Quantity of ſeed ſown.

The quantity of ſeed ſown for a crop of Wheat is in general from two to three buſhels. Mr. Marſhall ſays, pretty univerſally three buſhels an acre, in the midland counties, without much regard to the time of ſowing. That however ought to be attended to, and accordingly the Cotſwold farmers do attend to it, by ſowing in auguſt ſix pecks (about fourteen gallons), and in ſeptember two buſhels (of nine and a half gallons each). But it has been found that one buſhel ſown in auguſt, provided the land be clean and in heart, is abundantly ſufficient; and we may venture to ſay that one third of the ſeed Wheat ſown in moſt other diſtricts is ſaved in this [z].

It is remarkable that in the Vale of Gloceſter, though they ſow very late, yet the quantity of ſeed ſown there is conſiderably leſs than in other parts of the kingdom: even at Chriſtmas ſeldom more than two buſhels on an acre; in the more early part of the ſeaſon ſeven pecks is the uſual quantity. The meaſure being large, this is near ſeventeen gallons. But in Norfolk, three buſhels, containing near twenty-five gallons, are uſually ſown, ſome weeks perhaps before ſeed-time commences in this county. Two buſhels and a half (about twenty-two gallons), may be taken as the middle quantity of ſeed Wheat, throughout the kingdom [a].

At Michaelmas this quantity is commonly reputed moſt advantageous to ſow broadcaſt on a medium ſoil; a gallon of ſeed may be added to this for every fortnight later. But the quantity ſhould vary alſo with the quality of the land; a poor ſoil requiring more ſeed than a rich one [b].

In Suffolk, two buſhels are the common allowance of ſeed to an acre; ſome will ſow a peck more, and if late in the ſeaſon, even three buſhels: ſome however will, on good land truſt to ſeven pecks; but even in dibbling, that quantity is often put in [c].

In Northumberland they ſow from two to three buſhels; in Nottinghamſhire two buſhels; in Somerſetſhire two buſhels and a half or three buſhels; in Kent three buſhels; in ſome parts of the North Riding of Yorkſhire from five to eight pecks, in others ten or twelve pecks [d]: about Doncaſter in the ſame county they ſow four buſhels on an acre: a gentleman in that neighbourhood ſows only two buſhels, and thinks that his ſucceſs has been at leaſt equal to that of his neighbours, who ſow, or rather throw away, ſo much more ſeed [e].

It appears from a table in Young's Annals of Agriculture (16. 340.), that a leſs quantity of ſeed ſuffices in warm countries than in cold ones. This ſeems to be a conſtant rule founded upon the experience and cuſtom of people, wherever wheat is cultivated.

A pole is 16 feet and a half or 198 inches in length, and the number of ſquare inches in a pole is 39204. Now there being 160 poles in an acre, the number of ſquare inches in an acre is 6,272,640. Allowing

then one grain of Wheat to an inch, it will require that number of grains to an acre, or twelve buſhels, ſix gallons, and three quarters of a pint. For thirty-two grains taken from the middle of the ear make a penny weight troy; therefore an ounce contains 640, and a pound 6780 grains of Wheat, and a buſhel, 491,540 grains, ſuppoſing a buſhel of Wheat to weigh ſixty-four pounds troy, which is about fifty-ſix pounds avoirdupoids.

The following table will give the quantity of Wheat required to ſow an acre at different diſtances, from one to ten inches.

Inches	Buſhels	Gallons	Pints	Odd grains
1	12	6	¾	
2	3	1	4	1440
3	1	3	2¾	
4	0	6	3	360

Culture whilſt growing.

The growing Wheat is generally weeded in june and the beginning of july, by cutting up thiſtles and other perennial weeds with a ſmall angular hook, and by pulling up charlock and other annual weeds by hand.

When a dry ſpring ſucceeds a wet winter, it makes the ſurface of ſtrong land ſo hard, that the new or coronal roots cannot freely penetrate into the ſoil. This is diſcovered by the corn turning of a ſickly yellow. In this caſe the crop ſhould be harrowed once or twice in a place, and afterwards rolled.

In caſe the land is not ſufficiently rich, or has not been thoroughly manured, ſow top-dreſſings, or drench the crop with the drainings of dunghills, and immediately after harrow and roll. This ſhould be done as early in ſpring as the land is dry enough to bear the treading of horſes without poaching.

When worms or ſlugs attack Wheat, it is uſual to turn a flock of ſheep upon it; and ſome perſons ſend a boy with a dog to drive them about, in order to tread the more of the vermin to death.

After a froſty winter, the crowns of the roots are ſometimes expoſed for two or three inches in length; in that caſe, turning ſheep in after a moderate ſhower, and driving them about, will tread the Wheat into the moiſt ground, where it will produce freſh roots[f].

The practice of eating the Wheat in ſpring with ſheep is not uncommon, eſpecially when it is what is called winter-proud. It is alſo thought to have a good effect when the crop is thin, becauſe it occaſions it to tiller or branch more than it would otherwiſe have done[g]. It is alſo ſometimes eat down in autumn when it gets too rank from early ſowing; not however by a few ſheep kept long upon it, but by a large flock at once[h].

In the vale of Gloceſter Wheat is univerſally hoed; and this valuable operation is leſs difficult and more effectual in practice, than it appears to be in theory. Two hoeings are generally ſpoken of, but are executed only by good managers. One hoeing and a hand-weeding are eſſential to good management; for the early hoeing will unavoidably miſs many weeds, which afterwards run up to ſeed, and foul the ſucceeding crops. The firſt hoeing is begun in april, or as ſoon as the ſeaſon will permit; and ought to be finiſhed before the plants begin to branch or tiller. The ſooner the ſecond hoeing ſucceeds, the leſs difficulty there is in doing it; but the later it is given, the more ſerviceable it proves.

A thin crop requires a wide hoe; a thick crop, a narrow one. They are from three to five inches; made like the turnep-hoe, except that the corners are rounded off[i].

[f] Midd. ſurvey. 169. [g] Yorkſh. N. R. ſurvey, 113.
[h] Marſh. Gloc. 2. 53. [i] Idem. i. 118.

When Wheat is dibbled one row on a flag or furrow, it is always well hand-hoed; but if two rows, it is too thick to admit that operation conveniently. Sometimes however ſuch is alſo hoed[k].

Drilled crops are hoed once or twice, and hand-weeded where wanted. Theſe hoeings not only deſtroy the weeds, but make a good preparation for clover and graſs ſeeds, which ſeldom fail where this operation is properly performed[l].

Dibbling Wheat.

This excellent practice, which originated in Norfolk, is well eſtabliſhed in Suffolk. In the maritime ſand diſtrict, many thouſand acres are thus put in; and upon light lands after peas, where Wheat was formerly little cultivated. The ground being rolled with a light barley roller, a man walking backwards on the flag, as the furrow ſlice is called, with an iron dibber, the handle about three feet long, in each hand, ſtrikes two rows of holes, about four inches from one row to the other, on each flag; and he is followed by three or four children, to drop the grains, three, four, or five in each hole. In this way from ſix to ſeven pecks of ſeed are depoſited in an acre, at very equal depths, in the centre of the flag. A buſh-harrow follows to cover it. The expence is from eight to nine ſhillings an acre. The treading ſo equally is very beneficial upon light ſoils; and in dry weather hurtful upon none. The ſeed is laid in at an equal and proper depth; and it is all in the flag itſelf, not in the ſeams, where weeds, if any, will ariſe: and there is ſome ſaving in ſeed. The crops are ſuperior to the common, and the ſample is more equal. Some uſe a frame, which ſtrikes many holes at a time, but the work is not ſo well done. The ſyſtem of well-paid employment for the poor, which this practice carries with it, is of great importance.

This practice has lately been improved: a narrow ſet plough of only ſeven inches width at bottom, is uſed to plough with; then follows a one-horſe roll, to level the flag or furrow for the dibblers. It is ſufficient to depoſit two or three grains in each hole. Inſtead of buſh-harrowing, a two-horſe roll follows, afterwards the harrows twice in a place; when the field is finiſhed in this manner, it is harrowed up again obliquely; by this method the Wheat is depoſited in the middle of the flag, at nine inches diſtance in the rows; and when come up, has the appearance of being drilled: the two-horſe roller is of material uſe in cloſing up the holes, and preventing the Wheat from being diſturbed by harrowing; and the land is made ſo ſolid by rolling, that very little apprehenſions are entertained about the ſlug or worm. Six pecks of ſeed are enough for an acre[m].—Some talk of two pecks, and even one peck; others inſiſt upon eight or ten; and ſome, at the other extreme, tell us that almoſt as much ſeed ſhould be dibbled in as is ſown broadcaſt. Certainly very thin ſowing is bad economy. And this practice is better calculated for light, than for ſtrong land.

Mr. Marſhall, in his Rural Economy of Norfolk (vol. 2. 35.) gives an account of the firſt riſe of this practice, as well as the particulars of it.

Drilling Wheat.

Drilling Wheat is practiſed with great intelligence and ſucceſs by individuals in different parts of the country, but it is by no means common any where. The deficiency of the machines, the aukwardneſs of labourers in uſing them, and the ſmall quantity of ſeed recommended by the venders of them to be ſown, have been obſtacles to the general eſtabliſhment of this neat culture.

In all drilling, the land ſhould be well ploughed, and made fine, before the drill comes upon it, by rolling and harrowing; a one-horſe roll ſhould follow the drill, to cloſe the land upon the ſeed, and then the more the land is harrowed, the better; very little ſeed ought to be ſaved by drilling; for it is found by

 experience,

experience, that corn drilled in rows at nine inches aſunder, requires thickneſs in the ridges [n].

Others are of opinion that they get greater crops from wheat drilled in rows eighteen inches diſtant, and ſave half the ſeed [o].

Others again think that even nine inches are too far aſunder for the rows, except on very rich land, and conſider ſeven inches as the moſt profitable diſtance for the farmer. Theſe gentlemen allow that ſome ſeed may be ſaved, but they do not drill leſs than two buſhels to the acre [p].

It would be entering too wide a field, to determine the comparative merits of the broad-caſt and drill huſbandry. Much may be ſeen upon the ſubject in Mr. Young's Annals of Agriculture; and ſomething in the Bath papers, and the County ſurveys drawn up for the conſideration of the Board of Agriculture, and other publications.

On light ſoils it ſhould ſeem that drilling may be adopted to great advantage; but on clays and foul lands, the drills and horſe-hoes cannot work.

Tranſplanting Wheat.

That Wheat increaſes very greatly, where it has room to ſpread, by the branching of the roots, or tillering as it is called in ſome counties, or ſtocking, as in others, is a well known fact. It is alſo no leſs certain that plants of Wheat raiſed in a good ſoil, may be divided into ſeveral, and theſe again ſubdivided almoſt *ad libitum*; ſo as to produce a conſiderable quantity of grain from a ſingle ſeed. This may be illuſtrated from the following experiment, which was conducted under my own eye, in the botanic garden at Cambridge, by Mr. Charles Miller then Curator there. A few grains of the common red Wheat were ſown on the ſecond of june 1766. On the eighth of auguſt, one of the moſt promiſing plants was ſelected, and ſeparated into eighteen parts, each of which was planted ſeparately. Theſe were divided, as they would bear without injuring them, between the middle of ſeptember and the middle of october, and made in all ſixty-ſeven plants. Theſe were left to ſtand during the winter; and another diviſion of them made between the middle of march and the twelfth of april, produced five hundred plants. The ſubdiviſion might have been carried much farther; but theſe were deemed amply ſufficient to produce the quantity of grain ſtipulated for, which was half a buſhel.

The number of ears was ——————21,109.
The number of grains, by eſtimation, 576,840.
The meaſure 3¼ pecks and one quart.
The weight 47 pounds 7 ounces.

The plants were ſtrong, and were tied up to ſtakes to prevent their lodging. Some of them produced an hundred ears from a ſingle root. Many of the ears meaſured ſeven inches in length, and contained from ſixty to ſeventy grains. The ſoil was a blackiſh garden mould, but light and poor, and on a gravelly bottom; half the ground was well dunged, the other half had no manure, but little or no difference was diſcoverable in the plants. The whole was covered with nets to keep off the ſparrows.

The above account is given from my own minutes, made at the time on the ſpot. It may be ſeen in the Philoſophical Tranſactions, in the Annual Regiſter for 1769, and in the ſecond volume of Letters and Papers publiſhed by the Bath Agricultural Society.

Another experiment is communicated by Dr. Hunter of York.—In october 1795, a quart of Wheat was drilled in a piece of garden ground; and on the 22d of march, the plants were taken up, and tranſplanted into a field, which had borne a crop of potatoes; it contained 600 ſquare yards or half a rood, and the ſoil was a light loam. The land was only once ploughed, harrowed and rolled; after which the plants were pricked in at the depth of one inch, and at the diſtance of nine inches from each other; each ſquare yard containing ſixteen plants. The expence of planting was eſtimated at one guinea an acre, ſuppoſing the work to be chiefly done by women and children. The crop was neglected, not having been properly hoed. Beſides it was much blighted and mildewed, owing, as was ſuppoſed, to its growing in the middle of a field of very tall oats. The loſs by mildew and neglect, was eſtimated at ſix buſhels to the acre. The produce was eleven pecks, which is at the rate of twenty-two buſhels to the acre.

Another experiment was made on better Wheat land, and every neceſſary attention was beſtowed upon the crop. But it was planted a month later than the other, with a view to aſcertain the beſt time for tranſplanting. The conſequence was, that the plants were induced to tiller more than neceſſary during the whole ſummer. Upon the whole, the ſecond week in march ſeems the beſt time for tranſplanting Wheat; for about that time the ſecond roots begin to ſprout from the crown. The produce of this crop was four pecks on 101 ſquare yards, or the forty-eighth part of an acre, which is at the rate of forty-eight buſhels to the acre. The plants were nine inches from each other. From the great ſpace allowed for each plant (eighty-one inches), it was neceſſary to hoe two or three times during the ſummer. The ears of corn were in both experiments uncommonly long.

The advantages of this practice would be a conſiderable ſaving of ſeed; the employment of the feeble hands when there is little work; planting land in the ſpring, that was too wet for ſowing in autumn or winter; hoeing and keeping the land clean at a ſmall expence; and having a crop of turneps, cabbages, peas, beans, tares or potatoes, as preparatory to a crop of planted Wheat, inſtead of lying waſte under a ſummer fallow [q].

Another mode of tranſplanting Wheat has been ſuggeſted, by collecting ſeedling plants from the ſtubbles, which have been ſelf-ſown the preceding autumn. Theſe plants are of little utility to the farmer, and are ſometimes, by winds and other accidents, ſo abundant on the ground as to afford ſufficient ſtock to plant many acres. When the autumnal ſeaſon is unfavourable, theſe ſeedling plants might be rendered uſeful [r].

HARVESTING.

It is well known that Wheat is for the moſt part cut with the ſickle; in ſome parts, where ſtraw is more than ordinarily valuable, it is cut near the ground, but in moſt places at a conſiderable height. Men only or chiefly reap throughout the greater part of England. In the northern counties and in Scotland it is almoſt entirely done by women.

In the north riding of Yorkſhire, in reaping, provincially ſhearing, three women and one man make a ſet, who of a middling crop do an acre a day. If corn be thin, a man will bind after four women; if very thick, he requires a boy to make bands for him [s]. In Lothian, moſt of the reapers are women from the Highlands. A man binds to eight reapers, who generally cut two Scotch acres a day, the ſtubble being from four to ſix inches high. The ſheaves are made about twelve inches in diameter: fourteen of them form a ſtock or ſhock, covered with two ſheaves [t].

In Middleſex, Kent, Surry, and Weſt Devonſhire, Reaping, (provincially near London called *bagging*,) is moſtly done with a toothleſs hook of about twice the weight of a common ſickle. It is ſharpened in the ſame manner as a ſcythe; and the corn is cut by a ſucceſſion of blows, made within two or three inches of the ground. The reaper collects enough for one ſheaf at a time, binds and ſets it up in tens, called a ſhock. This bagging is, to all intents and purpoſes, mowing with one hand againſt the ſtanding corn. By this operation the ſtraw is cut much cloſer to the ground than can be done by hand-reaping; it is equally expeditious, and ſecures a greater quantity of ſtraw, which near London is a conſiderable object [u].

In Weſt Devonſhire this operation is called hewing. The hook is formed much like the common-reaping-hook, but ſomewhat larger every way, longer, broader

[n] Idem. 48. 50. [o] Idem. 51. [p] Bath papers, 6. 189.

Digitized by Google

broader and ſtouter, with a hooked knob at the end of the handle, to prevent its ſlipping. The corn is ſtruck at horizontally and almoſt cloſe to the ground with one hand; whilſt the other hand and arm ſtrike it at the ſame inſtant about the middle of the ſtraw; thus driving it upright againſt the ſtanding corn: the workman taking a ſweep round as much as will form a ſheaf, and collecting the whole together in the centre, into a ſort of leaning cone; finally ſtriking the hook under its baſe, to diſengage it entirely from the ſoil; but ſtill ſupporting it with the left arm and the leg, until the hook be put beneath it, to lift it horizontally to the band. Sometimes the hewer forces his way up one ſide of a narrow ridge, againſt the wind, and back on the other ſide, thus collecting half a ſheaf, and then fetching another half ſheaf in the ſame manner. If a crop of Wheat be free from weeds, and ſtand well, this method of cutting is expeditious and eligible enough; but if it be lodged, or ravelled, or foul at bottom, it is improper: at beſt it requires expert workmen to make good work. A ſcythe in good hands will do as well or better, and is ſtill more expeditious. To ſecure the ſcattered corn, women or boys collect and ſet up the ſheaves; and theſe are followed by women with rakes[x].

Much Wheat on the Yorkſhire wolds is mown againſt the ſtanding corn with a cradle ſcythe, bound in ſheaf, and ſet up in ſtooks or ſhocks, at the time of mowing[y].

Whenever there is any appearance of blight on Wheat, it can hardly be cut too early. The greenneſs of the ſtraw is no indication that the grain is not ripe; for it never gets to a bright yellow, but remains green till it turns abſolutely black. When the ſtraw is in this ſtate, the circulation of the ſap ceaſes, and the grain ſhrinks in ſize daily. Nothing can keep up its plumpneſs but cutting it, and laying it down on the ſtubble, to receive the dews; turning it frequently, and not tying it up, till the corn is dry and fit to carry. It will thus prove good marketable grain; whereas had it been left ſtanding longer, part would never have been threſhed out of the ears, and the reſidue would have been ſo light and horny, as to fly off entirely in the tailing. The ſtraw alſo will be tough and fit for thatching, which would otherwiſe have been beaten to pieces in threſhing[z].

It is the univerſal practice to tie up Wheat in a ſheaf, and to ſet up the ſheaves in ſhocks or ſtooks: but the ſheaves are made larger in ſome diſtricts than others, and the number of ſheaves that go to make a ſhock is not the ſame in all places. In general ſheaves are made too large, and much inconvenience reſults from it in a wet harveſt. The bands are commonly made by tying two handfuls together; but if the ſtraw be not very ſhort, one length will be ſufficient. In forming the ſhocks, ten or twelve ſheaves are uſually ſet together in two rows, without capping or other precaution againſt rain[a].

In Yorkſhire and ſome of the Midland counties Wheat is hooded or capped; that is, covered with two ſheaves inverted. Unleſs the ſtraw be long, two ſheaves are not equal to the ſafe covering of ten. It is therefore now the more general practice to ſet them up in tens. If Wheat be ripe, this is a ſafe and eligible practice, in a wet ſeaſon. But in fine weather the ears of corn cannot be too much expoſed to ſun and dews; or if the corn be cut green, or the grain be thin from mildew, or any other cauſe, it muſt be very improper to cover it, nay a ſlight ſhower is of great benefit to it. In covering of Wheat therefore the farmer ought to be directed, not by cuſtom but by the ſtate of the crop and of the weather[b].

In Weſt Devonſhire nine ſheaves are crouded together in a ſquare of three ſheaves every way, and a tenth is put over them, as a cloak or hood, the whole forming a ſort of cone or pyramid. This is a bad practice. The cloſe poſture of the ſheaves prevents a circulation of air; and in moſt caſes the covering is very imperfect, one ſheaf, unleſs it be very large and the ſtraw very long, not being ſufficient to ſecure the reſt from wet, but ſerving rather to conduct the rain into the centres of the upright ſheaves[c].

In Kent, between Sandwich and Dover, they cover the ſhocks (of from twelve to twenty ſheaves, in two rows) with cloths or mats, juſt wide enough ſecurely to cover about one third of the length of the ſheaf, and faſtened at each corner by a peg ſtuck into the ſheaf. Mats are more commonly uſed, which coſt ſeven-pence each. The expenſe is conſiderable, but the practice is found to improve the ſample ſo much that the Dover bakers give a clear preference to it[d].

In many parts of the Weſt of England Wheat is ſtacked, or mowed, as they call it, in the field, immediately after it is bound. Theſe mows are round, and uſually contain from a cart to a waggon load; they are drawn up to a point, and are covered with a ſingle ſheaf inverted. Thus the day's cutting is ſecured every evening; and the corn remains in the field frequently five or ſix weeks, till the farmer is at leiſure to take it into the barn or the great mow or rick. The men are very dextrous in making theſe mows, ſo as to prevent rain from injuring the corn. In a late harveſt, and a moiſt climate, eſpecially after a wet ſummer, which ſeldom fails of filling the butts of the ſheaves with green ſucculent herbage; thus ſecuring the ears from injury, and at the ſame time expoſing the butts to the air, ſeems a good expedient. The objections to it are, that mice are apt to be brought home in the ſheaves, and that the corn ſeldom has ſufficient dryneſs for winter threſhing[e].

In the reſt of England Wheat is carried immediately either to the barn, or to the great rick in the farm yard; theſe ricks are, or ſhould be ſet upon poſts, tinned ſtones or brick piers, capped with flat ſtones, and a frame of timber laid over them, to keep out vermin.

It is unqueſtionably an advantage to Wheat, to expoſe it as much as poſſible to the weather between cutting and carrying. If the ſeaſon be unſettled at the time of cutting, cover immediately, and as ſoon as the weather ſettles uncover; keeping the ears expoſed to the ſun, wind, dews and moderate ſhowers, until they are ſufficiently weathered. But if the ſeaſon be tolerably ſettled at the time of cutting, it is beſt to ſet the ſheaves up uncovered, and ſo to let them remain until the ears are opened, the chaff looſened, and the grain mellowed: then, if the weather be hazardous, they may be covered, until the butts are dry. In ſome caſes, in ſettled weather, it may be beſt not to tie up the corn immediately, but to let it lie upon the ſtubble for ſome time. The ſhocks ſhould be ſet up north and ſouth, not eaſt and weſt; for in the latter caſe the ſheaves on the north ſide will not be fit to carry till ſeveral days after thoſe on the ſouth ſide[f].

Threſhing and Cleaning.

Threſhing of Wheat, as is well known, is performed with a flail, and in all except very ſmall farms, on an oaken floor. Threſhers in moſt counties ſtrike inceſſantly without changing hands, or reducing the force of the blows, till the principal part of the grain is beat out on one ſide; they then turn the ſheaf, and repeat the operation on the other ſide: they next change hands, and ſtrike in an oblique direction, which draws the ſtraw from the ſheaf an inch or two at every ſuch blow, till the whole is compleated. This gives the threſher an opportunity of ſeeing and hitting every ear, till it is cleared of the grain: and it is the only method of doing ſo by the flail. This practice toſſes the ſtraw about and bruiſes it, conſequently it cannot be ſent in handſome truſſes to market: the threſhers therefore near London ſtrike with an irregular blow; their rule is to hit two or three blows rather ſmartly, and one or two ſo ſlightly as to be of little uſe, thus relieving themſelves from the neceſſary fatigue which the men of other places undergo in

threſhing

threſhing clean. This ſhifting or deſiſting from labour, with the neceſſary perpendicular blows for preſerving the ſtraw ſtraight, for the ſake of ſending it to market in handſome truſſes, is the reaſon of their not threſhing clean[s].

With the ſame view of keeping the ſtraw entire, not only for litter indeed, but for thatching, in the weſt of England, Wheat is not threſhed in the ſtraw, but the ears are cut off[h]. Or elſe the ears are threſhed lightly with the flail, or beaten acroſs a caſk by hand until the grain is got pretty well out of them. Then the ſtraw is ſuſpended in large double handfuls in a ſhort rope, fixed high above the head, with an iron hook at the looſe end of it, which is put twice round the little ſheaf, juſt below the ears, and faſtened by the hook laying hold of the tight part of the rope: the left hand being now firmly placed upon the hook, and pulling downward, ſo as to twitch the ſtraw hard, and prevent the ears from ſlipping through it, the butts are freed from ſhort ſtraws and weeds, by means of a ſmall long-toothed rake or comb. This done, the rope is unhooked, and the ſtraw laid evenly in a heap. A quantity of clean ſtraight unbruiſed ſtraw being thus obtained, it is formed into ſmall ſheaves, returned to the floor, and the ears threſhed again with the flail, or by hand over the caſk, to free it from any grain which might have been miſſed in the former beating. Laſtly, the ſtraw is made up into large bundles, of thirty-ſix pounds weight each, with all the ears at one end, and laid quite ſmooth and level[i].

Threſhing machines are now gaining ground, in ſome parts of the kingdom, particularly in Scotland and the north of England. They are yet too expenſive for any but great farmers; and perhaps it is not to be wiſhed that they ſhould be generally uſed, as in ſome part of winter the farmers would find it difficult to employ all the labourers were it not for the flail.

In Kent, Wheat is univerſally cleared with a caſting ſhovel, and flat broom called a ſpry, which ſweeps off the chaff, &c. This method is certainly the moſt expeditious and beſt, where the barn-floor is large, and of a ſufficient length: but in a ſmall room the winnowing machines will do it better, and perhaps cheaper[k]. A machine-fan is in uſe in ſome parts of Yorkſhire; it is too complex to come into general uſe, but if it could be ſimplified would probably be univerſally adopted. It was made by Sharp, and ſince by Winlaw[l].

Produce.

We have accounts here and there of heavy crops of Wheat. As of a piece of thirty-one acres near Lewes in Suſſex, which for ſix years together yielded from forty to fifty-ſix buſhels on an acre throughout[m]. The average at Mawby near Caſtor in Norfolk, for ten years together was forty buſhels; and from forty-eight to ſixty have been gotten there: but ſuch products are out of the common courſe[n]. In the ſurvey of the north riding of Yorkſhire, twenty-four buſhels to the acre is ſaid to be eſteemed a good crop, though in the beſt cultivated parts from twenty-eight to thirty-two buſhels are frequently obtained, and even forty buſhels are not rare[o]. In Middleſex the produce is ſtated to vary from under ten to upwards of forty buſhels to the acre; but twenty-four, or at moſt twenty-eight to be perhaps the average of the county[p].

Mr. Marſhall gives the average produce of the Midland Counties at twenty-four buſhels of nine gallons; and adds that from thirty-two to forty buſhels are produced, and on fifty acres together forty-five buſhels. But he juſtly remarks that this produce is very high[q].

On the Cotſwold hills in Gloceſterſhire, on the contrary, the average produce is only ſixteen buſhels: but theſe hills are better adapted to barley than Wheat[r].

[s] Middleſex ſurvey, 174. [h] Somers. ſurvey, 97. [i] Marſh. Weſt. 1. 181. [k] Kent ſurvey, 84. [l] Marſh. York. 1. 281. [m] Young's ann. 29. 445. [n] Idem. 12. 45. [o] Survey, 116. [p] Survey, 175. [q] 1. 238. [r] Marſh. 2. 56.

Mr. Young ſays, that the crops in Suffolk vary from twelve buſhels on ſands, to twenty-eight on rich loam, and that thirty-two and forty buſhels on an acre are not uncommon crops. He ſtates however twenty-two buſhels as the average of ſeven years[s]. Mr. Howlett alſo gives the average for Eſſex at twenty-two buſhels of eight gallons and a half[t].

I am diſpoſed to admit the laſt as a fair average for a great part of England. Heavier crops are very partial, and by no means to be depended upon in a general account. In making that out, conſiderable deductions even from twenty-two buſhels ought perhaps to be made, for ſlovenly farmers, improper ſoils ill managed, untoward ſeaſons, ſmut, mildew, inſects, &c. I have reduced the above ſtatements to buſhels, becauſe every body does not know that a comb is four, and a quarter eight buſhels; that a load in ſome places is forty buſhels, in others only five.

Diſtempers.

Mildew, or more properly *Meldew*, from an old but falſe notion that this diſtemper is occaſioned by a honey dew falling upon the ſtraw from the air. It is now generally ſuppoſed to be a ſpecies of Fungus, which cauſes the black or red ſpots in the ſtraw, and like other paraſitical plants draws to itſelf that nutriment which ſhould go to the increaſe of the grain.

Mr. Nesfield ſuppoſes that Mildew in Wheat is occaſioned by froſts late in the ſpring, or in the early part of ſummer; that the froſts moſt likely to cauſe it are ſuch as follow warm days, from the time that the Wheat is pretty far advanced upon the ſpindle, that is in general from about the 20th of may to the 10th of june; that the effect of theſe froſts is leſs or more pernicious according as they are or are not immediately followed by gentle ſhowers; and according to the real or only apparent vigour of the Wheat, which depends chiefly upon the nature of the ſoil and the ſtate of the weather, as to wet or dry through the winter. A thin crop upon a looſe ſoil will almoſt certainly be mildewed, not being able, from its luxuriancy, to reſiſt the ſlighteſt froſt late in the ſpring. And if it be too thick, it will have a weakneſs equally liable to injury. Wheat on fallow is, in general, more ſubject to mildew than that on clover-lay, except on very ſtiff ſoils[u].

In contradiction to this theory, Mr. Young remarks, that in 1791, the ſpring froſts were uncommonly ſevere; particularly that on the ſeventh and eighth of may there was ice a quarter of an inch thick, and on the 25th a ſtill ſharper froſt; and yet there was mildew, in hills or in vales, in forward luxuriant crops or ſuch as were backward and poor[x].

Mr. Jenkinſon obſerves, that at leaſt in the northern part of England, froſt is the moſt general cauſe of this malady, and ſometimes wet ſtormy weather. When it proceeds from froſt, and the mildew is only partial, then low hollow places, and ground much confined only ſuffer. When grain is near ripe, it is ſooner affected, but the damage is not ſo great as when it is farther from maturity. When the froſt is attended with a thick fog, almoſt inevitable deſtruction enſues[y].

Modern obſervers know, ſays Fontana, that the Mildew appears when a ſcalding ſun and cold nights ſucceed ſtrong dry fogs; the nutritive juice being contained during the night in the ſmall veſſels of the plant near the epidermis, which, being heated with the ſun, is diſordered, ferments, and burſts thoſe ſmall veſſels, forming a cautery whence the humour proceeds; and as the fibres and veſſels break with the leaſt reſiſtance, and more eaſily open lengthways than croſſways, ſo the mildew, or the ſpots of that diſeaſe, that is to ſay, the paraſitical plants which find a commodious ſituation in thoſe apertures, ſpread themſelves the whole length of the plant, but no ſpot is obſerved croſſways. The ſeeds of the mildew, or the buds of the paraſitical plants of which the air is full, as with the ſeeds of a thouſand other microſcopic plants, are depoſited in theſe wounds or apertures,

[s] Survey, 53. [t] Young's ann. 13. 188. [u] Idem. 1. 330. [x] Idem. 16. 423. [y] Idem. 3. 318.

take

Digitized by Google

take root within them, and meeting with the ſickly humour, which however is capable of nouriſhing and fructifying them, they quickly adhere and fix themſelves in theſe parts [z].

Mr. Marſhall aſks, whether the Mildew or Blight is not cauſed, or at leaſt encouraged by a ſucceſſion of wet ſeaſons? It is well known that the diſeaſe is moſt injurious in a wet ſeaſon. An old man, who has obſerved a particular farm fifty or ſixty years, ſays that the blight comes on at once, about the end of july; and that Wheat, which is forward enough to be filled by that time, eſcapes it [a].

In 1785, a ſtrong blight took place the beginning of auguſt. The ſtraw of backward crops was much diſcoloured; and the north ſides of ſome lands were much mildewed, whilſt the ſouth ſides were not. It was evident from this and every year's obſervation, that the forwardeſt Wheats are leaſt liable to be blighted; and that having paſſed a certain ſtage of ripeneſs, no obvious injury is incurred. No perceptible blight took place this year, whilſt dry weather continued; but no ſooner was ſhowery weather uſhered in, than a blight became obvious [b].

I do not know any thing ſo likely to diſcover the cauſe of the Mildew, as an accurate obſervation of the ſeaſons, from the time of the Wheat's coming out of the ground, to its flowering and beginning to mature the grain.

In the year 1803, the Wheat was much mildewed in the midland and eaſtern counties. There were catching froſts of ſhort duration in october, november and december 1802. From the 10th to the 21ſt of january 1803 there was froſt, with ſnow on the 17th and 19th. Towards the end of the month there was more ſnow and ſome froſt, and on the 26th the thermometer was at 21° at noon out of doors. The firſt half of february froſt and ſnow; the latter half wet and windy. From the third to the 11th of march froſt and ſnow, but the reſt of the month mild. April was mild till the latter end, when there were cold winds, and covered weather with ſtorms of hail. May was in general wet and windy, but not cold. June was very wet, and the 28th was foggy: ſo was the firſt of july. That month was various, but in general warm and moiſt; on the ſecond and 20th thunder; on the fourth the thermometer was at 77° and on the 15th at 63°. Here was much wet, but no late froſts previous to this mildew. The thermometer never was below 54° during the month of may; nor below 62° in june, ſo that there could not well be any froſt to ſignify all that time.

The Barberry is ſuppoſed to blight Wheat partially to a certain extent. It is a common notion in Norfolk, and accordingly the farmers have induſtriouſly extirpated this ſhrub from their hedges. It cannot be accounted for from the farina of the Barberry being ſhed over the flower of the Wheat; becauſe the Barberry is out of flower before the Wheat ſhoots up into ear. Such ſtrong atteſtation is given to the fact, that there is no diſputing it, though we cannot at preſent account for it; and Mr. Marſhall, who had ridiculed the notion, aſcertained the fact by an experiment [c]. See *Berberis*.

The only guard, ſays Mr. Marſhall [d], which the farmer has againſt the attack of this ſecret enemy appears to be, at preſent, that of ſowing early. But may not ſomething lie within the power of manure or tillage? Perhaps ſodburning might be ſerviceable as a preventive.

The chief remedy, according to Mr. Nesfield is, every thing that tends to give ſtrength, not luxuriancy; ſuch as ſowing upon clover-lays manured with compoſt or clay, as beſt ſuits the ſoil; as little pulverization by ploughing as poſſible, unleſs in ſtrong clay ſoils; feeding in the ſpring, if the Wheat be too florid; rolling light ſoils, &c. [e]

But when Wheat is once fully attacked with this fatal diſeaſe, the only remedy is to reap it as ſoon as poſſible.

Fontana informs us, that he took ſome green plants of corn, which appeared to be moſt affected with the mildew; the grains were ſo unripe, that a milky fluid iſſued from them when preſſed; but the ſeaſon being hot and every thing drying apace, he ſoon found the grain hard and reſiſting; it was lighter than the good ripe corn, and even ſomewhat withered, but it was full of a fine white meal, of an excellent quality. The Wheat reaped from the ſame farm had not yielded one tenth part of the ſeed. Many farmers in Tuſcany, the Bologneſe and Romagna, at the firſt appearance of the mildew had cut their corn green, and had moderate crops, but conſiderably greater than their neighbours in the ſame circumſtances, who waited until the cuſtomary time of harveſt [f].

Mr. Marſhall gives us a well authenticated inſtance of the good effect of cutting mildewed Wheat whilſt very green. A fine piece being lodged by heavy rains, and being ſoon after perceived to be infected with the mildew, was cut, though ſtill in a perfectly green ſtate: namely, about three weeks before the uſual time of cutting. It lay ſpread abroad upon the ſtubble until it became dry enough to prevent its caking in the ſheaf; when it was bound, and ſet up in ſhocks. The grain, though ſmall, was of a fine colour, and the heavieſt Wheat which grew upon the farm that ſeaſon, owing no doubt to the thinneſs of its ſkin. What appears more remarkable is, that the ſtraw was perfectly bright, without a ſpeck upon it [g].

It is a received idea in a part of Yorkſhire, that Meſlin or wheat and rie together, is never affected by the blight or mildew, and that the nature of rie is ſuch, that a very ſmall quantity of it ſown among Wheat prevents this deſtructive effect [h].

Mildew is a diſeaſe incident to the ſtraw of Wheat, but ultimately affecting the ear. *Smut* or *Brand* affects the grain directly, by converting it into a black duſt like ſoot, whence in many counties it is called *Burnt* (corruptly Bunty) Wheat.

Some are of opinion that this diſeaſe is generated by a very wet ſeaſon happening during the time that the Wheat is in bloſſom, and that it is propagated and continued, by uſing the corn thus vitiated, for ſeed. Mr. Wimpey drilled part of a ridge with good ſound ſeed; another part immediately adjoining with ſeed taken from very ſmutty corn, waſhed in two waters till no blackneſs remained, and carefully ſkimmed; and a third portion adjoining, with the ſame ſmutty Wheat unprepared. The crop from the ſound ſeed was perfectly free from ſmut: that from the ſecond had many ſmutty ears among it, perhaps one in twenty: the third had at leaſt half the ears infected [i].

Mr. Arthur Young ſowed fourteen beds, with the ſame ſmutty ſeed. That which was ſown dry, and alſo that which was well waſhed in clean water, turned out very ſmutty: that waſhed in lime water, was the next in order for badneſs, but much better than the two others; then thoſe which were waſhed in a lye of wood aſhes, and in a mixture of arſenic and ſalt; and next that which was ſteeped in lime water four hours: thoſe which were ſteeped in the lye four hours, in lime-water twelve hours, in the arſenic ſteep twelve hours, and in the ſame twenty-four hours, had very few ſmutty ears, and that which was in the arſenic ſteep four hours, had only one ſmutty ear: thoſe which were ſteeped in the lye twelve hours, in the lime water twenty-four hours, and in the lye twenty-four hours, had none [k].

Though the uſe of ſteeps to prevent the ſmut has been in uſe for many ages, and innumerable experiments have been inſtituted and caſes have occurred, which prove their efficacy; yet there are ſtill perſons who think that they are of no uſe, any farther than as they ſeparate light grains and ſeeds of weeds, and guard the ſown Wheat againſt vermin.

That it is not the ſeaſon alone, as ſome inſiſt, that occaſions the ſmut in Wheat, is plain, becauſe it has

frequently happened, that a field having been moſtly ſown with grain prepared according to cuſtom, the ſeedſman finding that a ſufficient quantity had not been ſteeped, has taken ſome dry out of the barn to finiſh: and the latter has proved very ſmutty, when the former was clean and ſound.

It would take up too much room to enter into this controverſy. We muſt refer therefore to Young's Annals, vol. 4. p. 202. 6. 173, 243. 8. 115, 181, 407. 10. 434. 16. 311. Marſhall's Midland Counties, 2. p. 13. Bath letters and papers, vol. 5. p. 244, 270. vol. 6. 116, 186. &c.

Smutty Wheat may be made a' tolerably good ſample, by waſhing and ſtirring it well about in two or more waters, and then kiln-drying it by a very moderate fire[l].

To avoid the danger of Smut every prudent farmer will ſow ſound uninfected ſeed, brine and lime it well, and get it into the ground as ſoon as the ſeaſon and condition of his land will permit.

Of late years a minute inſect has been remarked to do conſiderable damage occaſionally to the Wheat crop. It is called Tipula tritici, and is deſcribed, and the hiſtory of it given at large, in the third and fourth volumes of the Tranſactions of the Linnean Society of London. It varies from a yellowiſh white to a deep yellow. In a ſingle flower of the ear there are ſometimes thirty, and ſeldom fewer than eight or nine larvæ or caterpillars of this minute fly. The greateſt part of theſe are providentially deſtroyed in their pupa or chryſalis ſtate, by a friendly Ichneumon, which lays one egg in each pupa. The larva appears to feed upon the pollen or duſt of the anthers, for in thoſe florets in which it reſides the germ never ſwells. It does not appear that the grain is injured in any other way by this inſect, but it invariably produces the inanition of it in the floret which it inhabits. It may always be detected by the diſcoloured appearance of the baſe of the corolla, which is its uſual ſtation.

To aſcertain the quantity of miſchief produced by this inſect within particular limits, Mr. Kirby went into a field of fifteen acres, partly of red and partly of white Wheat; and took five ſtations, one on each ſide, and one in the centre. The reſult was, that in thirty ears of white Wheat, ſeventy-three grains were deſtroyed, or not quite two grains and a half to an ear; and in twenty ears of red Wheat, twenty-nine grains were deſtroyed, which is nearly a grain and half to an ear, on the whole, about two grains to an ear; which might be near a twentieth part of the produce, and would make a difference of at leaſt twenty buſhels in the crop. Leaſt miſchief ſeemed to be done on the ſouth ſide of the north hedge, but no part eſcaped wholly. In a field which was ſown later, there was ſcarcely any of theſe grubs; but it was much infeſted by a ſpecies of Aphis or plant-louſe, called in ſome places the Dolphin.

The red-gum, which is undoubtedly a kind of Fungus, is totally unconnected with theſe inſects. In the field where Mr. Kirby found an infinity of the larvæ of the Tipula tritici, and Thrips phyſapus, he ſcarcely ſaw any florets which produced this little plant called the red-gum; but ſome ears of a kind of bearded Wheat, which he cultivated in his garden, were quite diſcoloured by it, without any larva attending upon it. Of all the inſects that are found in Wheat, this laſt, in all its ſtates, is by far the moſt numerous, and ſeems to derive its nouriſhment from the grain, though ſome doubt it[m].

The Tipula tritici, ſays Mr. Ruggles, ſo accurately deſcribed by Mr. Kirby, has laſt year (1799), in all the country about Finchingfield in Eſſex, and alſo about (Clare) his other place of reſidence in Suffolk, extended itſelf in quantity and miſchief to a ſurpriſing degree, inſomuch that he is convinced, from repeated facts expoſed to his obſervation in his own farms in the two counties, and alſo in thoſe of his neighbours, that where no mildew or red-gum affected the Wheat, and no other apparent cauſe than this inſect, the crop of laſt harveſt has been deficient one third, if not more. He received the ſame or ſimilar accounts from different farmers in both counties; and found that the damage done to moſt of the ears of Wheat was a total deſtruction of all the grains, eſpecially where the yellowneſs of the chaff appeared early. He remarks, that theſe inſects particularly infeſt the American Wheats, which on account of their plumpneſs and weight have been generally ſown in his neighbourhood; and ſuggeſts a hint whether, as it has not been long obſerved, it may not have been recently introduced.

In the beginning of december 1800, on the examination of ſome Wheat out of a field very much tainted with this inſect, Mr. Ruggles found in the chaff of the ear, which appeared to him, by feeling it, leaſt filled with the grain, ſeveral little neſts of theſe minute yellow grubs ſtill alive, which proves that they are not all killed that remain after the ichneumon is produced. And a tenant of his, who had dreſſed a conſiderable quantity for ſeed, informed him, that the boſom of the heap, after it was thrown, was totally diſcoloured of a high yellow, from the quantity of grubs which had been beaten out of the chaff by the flail.

Mr. Ruggles alſo obſerved, that many kernels of Wheat in theſe diſeaſed ears, had the appearance of one or two very minute, white ſpecks about the germ, and thoſe which ſo appeared were particularly tender about that part. If theſe ſpecks be the eggs of the future larva, the continuation of the inſect from its egg ſtate may be eaſily conceived; for if the egg be attached to the eye or germ of the mature grain, and be ſown with it, the alarming increaſe of this diſeaſe may eaſily be accounted for[n]. Till this laſt obſervation be verified, I ſhould rather conceive, that the fly lays her egg in the ear of Wheat, probably at the baſe of the chaff, whilſt it is yet in a tender ſtate. But this ſubject merits the farther attention of Mr. Ruggles and the ingenious entomologiſts who have ſtarted it.]

5. Poliſh Wheat growing tall, and having long heavy ears, is very ſubject to be lodged; and therefore is little regarded by farmers; but as it produces much flour, it might on that account be worthy of cultivation.

[6. Spelt is common in many parts of the continent. In Spain they ſow it in ſeptember or october, and it ripens earlier than any other corn; for which reaſon it is of great uſe to the poor, although it is a light grain, yields but little flour, and the bread made from it is indifferent[o].]

13. This has a creeping root, which ſpreads far in the ground, and is a very troubleſome weed in gardens and arable land; for every ſmall piece of the root will grow and multiply exceedingly, ſo it is very difficult to extirpate where it once gets poſſeſſion: in gardens, the common method of deſtroying it is, to fork out the roots as often as the blades appear above ground; where this is two or three times carefully repeated, it may be totally rooted out; but when the ſurface of the ground is very full of the roots of this graſs, the ſhorteſt way of deſtroying it, is to trench the ground two ſpits and a ſhovelling deep, turning all the couch into the bottom, where it will rot, and never ſhoot up; but this can only be practiſed, where there is a ſufficient depth of ſoil; for in ſhallow ground the roots cannot be buried ſo deep, as to lie below the depth to which they naturally ſhoot.

Where the roots of this graſs get poſſeſſion in arable fields, it is very difficult to root out again; the uſual method is by laying the land fallow in ſummer, and frequently harrowing it well over to draw out the roots: where this is carefully practiſed, the ground may be ſo well cleaned in one ſummer, as that the roots cannot much injure the crop which may be ſown upon it; but ſuch land ſhould be cropped with beans, peaſe, or ſuch things as require the horſe-hoeing culture; for where the land can be frequently ſtirred and harrowed afterward, it will be of great ſervice in cleaning it from the roots of this graſs and other bad weeds.

[Several of the perennial graſſes are comprehended

by

by husbandmen under the name of Quich. The black Quich, so troublesome in dry arable land, is the *Agrostis vulgaris*. The creeping red-stalked Bent-grass, *Agrostis stolonifera*, is the worst Quich-grass on strong wet lands. The dogs-grass, *Triticum repens*, is the Quich of gardens, and is common both on sand and clay, running prodigiously in the former, and bedding itself almost inextricably in the clods of the latter. Several others of the perennial grasses interfere in a less degree with the growth of corn, and as they have all the habit of establishing themselves in the ground when it lays in turf, summer fallowing becomes necessary for their extirpation previous to sowing Wheat; for that can be only partially effected by hoeing, or in any other way than by repeated deep summer ploughings; and as mixed soils, which are too moist for turneps, have a particular propensity to the production of these grasses, summer fallowing becomes absolutely necessary, and every attempt to crop without it, for any length of time, on such land, has terminated to the injury of the land, and the loss of the occupier[p]. We may add, that the radical extirpation of Quich and other root-weeds, is the only case in which a naked fallow is ever necessary; and that when this is once well done, it need not be repeated for many years, provided a proper attention is given to the management of the land.

On sands, Quich may be destroyed by strong harrowing, collecting into heaps, and burning.

Leaves ovate undivided, sometimes but rarely lobed.]

DECRIPTIONS, &c.

1. This rises with an upright stem to the height of six or seven feet; towards the bottom it becomes woody, and at top divides into four or five branches. Leaves placed alternately the whole length of the stem, about two inches and a half long, and almost two inches broad near the base; divided almost into three lobes toward the top, and the middle division ending in an acute point; they are veined on their under side, are covered with a soft brown down, and have several nerves running from the midrib to the sides; their upper side is of a yellowish green, and a little hairy; their borders are acutely but unequally serrate, and stand upon foot-stalks an inch in length. The branches are terminated by long spikes of flowers, which come out in clusters from the side of the principal foot-stalk, at the distances of about an inch. The flowers are small, the petals narrow and of a yellow colour: they are succeeded by burry capsules, somewhat like those of Agrimony, but round, and with longer prickles placed on every side.

[Jacquin only remarks, that it is an upright branching shrub, eight feet high; and that the flowers have no vestige whatsoever of a calyx.

Gærtner describes the pericarp as a globular coriaceous capsule, echinated with little hooked prickles hispid backwards, quite entire, three-celled but more frequently four-celled, valveless and not separable into little grains. Seeds solitary, ovate, convex on one side, angular on the other, smooth, hard, ash-coloured, fastened to the inner angle of the cells near the top.

Native of Jamaica, Martinico, and other islands of the West Indies, the Bermudas, and Brazil.—Cultivated here in 1739, by Mr. Miller[q].] It flowers in july and august, and in warm seasons the seeds sometimes ripen in England.

[2. Branches woody, round, villose. Leaves petioled, alternate, frequent, three inches long, gradually smaller upwards, softly villose on both sides

[p] Pitt's Staffordsh. survey, 50.

[q] Hort. kew.

Digitized by Google

with ſtellate hairs, but greener above, marked with lines along the nerves, ſerrate with the lower ſerratures of the upper leaves glandular, entire at the baſe. Petioles ſhort, villoſe with ſtellate hairs. Stipules awl-ſhaped. Flowers from the axils of the upper leaves. Germ covered with minute briſtles. It differs from the velutina (n. 4.) in having the leaves only half the width, not angular towards the outſide, acute not acuminate, with the hairs beneath more diſtinct, and the ſtipules ſetaceous-ſubulate[t]. Native of Arabia Felix and India.

3. Root annual. Leaves reſembling thoſe of currants. Flowers ſmall, purple or roſe-coloured. —Capſule ſpherical, white-tomentoſe, echinated with briſtle-ſhaped, hooked, ſmooth little prickles, four-grained, quadripartile: grains coriaceous, convex on one ſide, angular on the other, two-celled, valveleſs, growing to the ſeeds. Seeds ſolitary, two in each grain, and eight in the whole, from an ovate drawn to a point upwards, convex on one ſide, angular on the other, ruſeſcent. Sometimes the capſules are only three-grained and tripartile; others may eaſily be divided into ſix or eight parts, ſo that each ſeed is covered with its proper cell, as in ſome of the Malvaceæ. This differs therefore from Triumfetta, not only in the calyx, and five globular nectaries at the baſe of the petals, but in its many-grained capſule and confined ſeeds[u]. Linneus alſo, in his firſt works, conſidered this plant as a middle ſpecies between this genus and Urena, and did not allow it to be a Triumfetta, on account of its having a corolla. But he changed his mind, when he publiſhed the thirteenth edition of his Syſtema Vegetabilium. Native of the Eaſt Indies.

4. Stem ſoftly villoſe, round. Leaves petioled, alternate, from two to three inches long, five-nerved, unequally ſerrate, ſoftly villoſe above, hoary with minute ſubſtellate hairs beneath, very ſoft, entire at the baſe. Stipules lanceolate, attenuated, ciliate, ferruginous. Flowers in the upper axils. Native of the Iſle of France[t].

5. Native of the Society Iſles[u].

6. Stem fruteſcent. Leaves alternate, a hand long, equal in length and breadth, ſmooth above, ſeven-nerved, appearing rough beneath with very ſmall ſtellate hairs, when examined with a magnifier; the nerves, eſpecially at the baſe, have fewer but longer hairs; they are veined, unequally ſerrate, with the three or five ſerratures next the petiole glandular, ſubcordate at the baſe, divided above into three ovate diſtant acuminate lobes. Petioles rough-haired, but becoming ſmoothiſh by age. Panicle terminating, diffuſed: branches hirſute, leſs hairy at the tip, twice or thrice dichotomous, alternate, the two laſt oppoſite. Flowers pedicelled, aggregate at intervals, ſmall, ſolitary at the diviſions. Calyx hoary. Native of the iſland of Santa Martha in America; where it was found by von Rohr[x].

7. This is an upright branching ſhrub, ſix feet high. It is ſo like the firſt ſpecies in its habit, that at firſt ſight they might eaſily be miſtaken; but the flowers of this have always a calyx[y].

Browne ſays, it frequently riſes to the height of ſix or ſeven feet, where the ſoil is rich and moiſt; the flowers, which generally grow in two diſtinct parcels near the axils of the leaves, are ſuſtained by a few narrow ſtipules, that perform the office of an involucre; half the capſule is echinated, the other ſmooth.

The leaves and tender buds, infuſed in water, yield a fine clear mucilage, from whence we may conclude this plant to be a good emollient. The bark is tough and ſtrong, and ſerves for ropes, and other conveniences of that kind, in the inland parts of the country.

Native of the Weſt Indies. Introduced in 1773 by John Earl of Bute. It flowers in july[z].

8. This differs from the other ſpecies, in having the corollas twice or thrice as large.—Stem woody, round, with the branches ſmooth below, rough-haired above, bifid at the end. Leaves alternate, two or

[t] Vahl. [u] Gærtner. [x] Vahl. [y] Jacquin. [z] Hort. kew. [u] Forſter.

three inches long, a little attenuated, three-nerved, ſomewhat rugged, having a few hairs either in bundles or ſingle ſcattered over the upper ſurface, leſs hairy underneath, ſerrate, the alternate ſerratures larger, the four loweſt terminated by an orbicular hollow gland. Petiole two inches long, thicker near the leaf, aſh-coloured with ſtellate hairs. Stipules lanceolate, acuminate. Lower peduncles axillary or oppoſite to a leaf, many-flowered: partial umbelled; terminating with partial peduncles racemed: pedicles umbelled, two or three-flowered, tomentoſe as the common peduncle is, and rough-haired. Bractes lanceolate. Calyx ſmooth, with lanceolate acuminate leaflets. Petals oblong, clawed, a little ſhorter than the calyx. Style longer than the calyx. Native of Montſerrat, where it was found by Ryan.

9. Branches round, tomentoſe as the whole plant is. Leaves alternate, five or ſix inches long, as wide in the middle as they are in length, ſpreading very much, without any ſinus at the inſertion of the petal, ſerratures frequent, alternately larger and blunter, the lower ones glandular; they are ſoft on both ſides, but more villoſe underneath, veined; the lower ones five-nerved, the upper ones three-nerved. At the inſertion of the petiole on each ſide are two brown approximating glands. Petioles two inches long, round. Stipules lanceolate, attenuated, ſmooth within. Peduncles from the upper axils, often ſeveral, ſome ſimple, others compound: pedicels umbelled, with brittle-ſhaped bractes at the baſe. Calyx five-leaved, with linear acuminate leaflets. Petals five, linear, length of the calyx. It reſembles T. Lappula, but the flowers being calycled it ſhould ſeem to be different. It may be diſtinguiſhed from T. rhombeæfolia by the form and tomentoſeneſs of the leaves. Native of South America, where it was found by von Rohr[a].

10. This is an upright branching ſhrub, three feet in height, the whole having an unpleaſant ſmell, eſpecially the ſeeds. Branches ſubdichotomous. Leaves alternate, ſubſeſſile, ſerrate, acute, entire, wrinkled, villoſe, the upper ones leſs rhomboidal. Flowers very numerous, with yellow petals, and red calyxes, on many-flowered, very ſhort, axillary and aggregate peduncles; hence they are in whorls. A cell or two is often wanting in the pericarps, but they are moſtly ſix-celled. It differs from T. Bartramia in the leaves not being angular. The French call it Couſin, on account of the capſules adhering to the clothes. Native of the Weſt Indies[b].

11. This is an annual plant, riſing about two feet and a half high, and ſending out ſeveral branches on every ſide. Leaves ending in long acute points, ſome are heart-ſhaped, others have an angle on each ſide towards the point; they are from three to four inches long, and almoſt as much in breadth where broadeſt; they ſtand upon very long footſtalks, and are notched on their edges. The flowers come out in long looſe ſpikes at the top of the plant: they are ſmall and yellow: ſome have four petals and eight ſtamens, others five petals with ten ſtamens. Fruit roundiſh, burry, four-celled, with one ſeed in each cell. Native of India. Cultivated by Mr. Miller before 1760, though it is not inſerted in the editions of his Dictionary of 1768 and 1771. It flowers in ſeptember and the ſeeds ripen in november[c].]

PROPAGATION AND CULTURE.

1. Sow the ſeeds on a hot-bed early in the ſpring; when the plants come up, tranſplant each into a ſeparate pot filled with light, freſh, kitchen garden-earth, and plunge them into a moderate hot-bed of tanners' bark, ſhading them from the ſun until they have taken new root, and then treating them in the ſame manner as other tender exotic plants. In autumn remove them into the bark ſtove, and refreſh them with water frequently, except in very cold weather. If the plants live through the winter, they will flower the following ſummer, and ripen their ſeeds in autumn; but may be continued two or three years if carefully managed.

DESCRIPTIONS, &c.

1. Root perennial, fibrous, black; from which ſpring up many leaves reſembling thoſe of Wolf's-bane, cut into five ſegments almoſt to the bottom. The ſtalk riſes almoſt two feet high; it is ſmooth, hollow, and branches toward the top. Each branch is terminated by one large yellow flower, ſhaped like that of Crowfoot, but without any calyx. The corolla is compoſed of ſeveral (about fourteen) concave petals, the points of which are turned inwards, ſo as almoſt to cloſe up the ſtamens and piſtils, and the whole is of a globular form, whence its name of Globe-Ranunculus or Globe-Crowfoot.

[Stem upright, round. Leaves many-parted, pinnatifid, gaſhed, ſmooth; the lower ones on long petioles [e]: round, entire at the baſe, jagged upwards; theſe again deeply divided into three, the middle diviſion trifid, all ſharply ſerrate or jagged on the outer edge, nearly entire on the inner [f]: ſtem-leaves ſubſeſſile, alternate. Nectaries linear-ſpatulate, ſcarcely equal to the ſtamens, ſhorter by half than the petals. Stamens linear: anthers curved in [g]. Capſules numerous, above thirty, collected into a head, ſubcylindrical, curved inwards, ribbed tranſverſely, mucronate at the end [h], (or terminated by a crooked horn; pointing outwards; and giving the head a ſtar-like appearance [i]:) they are one-celled, and open on the inner ſide. Seeds numerous, about twelve in each capſule, ſmall, angular, black and ſhining; faſtened to the opening future. [k] Leers ſays there are only four ſeeds in a capſule. Native of the North of Europe, Carniola, Dauphiné, Piedmont, Siberia. In the northern counties of England, in Wales, and Scotland, on the ſides of mountains, and mountainous meadows, in moiſt ſhady places. Mr. Miller found it in great plenty in the park of Burrow-hall in Lancaſhire. Mr. Curtis in Skirrith wood, and moiſt woods about Settle in Yorkſhire. Mr. Woodward, near Troutbeck in Weſtmoreland. Mr. Atkinſon, at the road ſide near Dale Park, in Furneſs Fells. Mr. Robſon, in the marſhes of the county of Durham. In Scotland, at Drumlanrig in Nithſdale; at Corrys-Lyn, the famous fall of the Clyde; at Cartland rocks near Lanerk; in Carubber-Den near Linlithgow; and in Achendenny wood. It is too common in the north to ſpecify more places of growth. In the ſouth it is ſeen only in gardens. It flowers at the end of may and beginning of june. In the northern counties it is called Locker-goulans; which I ſuppoſe is corrupted from the Lucken-Gowan (Cabbage Daiſy) of the Scots.

Digitized by Google

This ſplendid flower, ſays Linneus, adorns the pavements of the ruſtics, on feſtival days. [l] Allan Ramſay makes his young laird wiſh to gather theſe flowers to weave a chaplet for his Katy's brow [m]. In Weſtmoreland this plant is collected with great feſtivity by the youth of both ſexes about the beginning of june; at which time it is uſual to ſee them return from the woods in an evening laden with it, to adorn their doors and cottages with wreaths and garlands.

In habit and ſenſible qualities the Trollius agrees with Hellebore and Ranunculus, but is leſs acrid than moſt of them [n].

Cluſius ſays, that in 1581 he ſaw it at London, having been then newly brought from the mountains of the north.]

2. The Siberian Globe-flower differs from the firſt in having larger leaves, of a lighter green colour, with fewer and larger ſegments, reſembling thoſe of yellow Monk's-hood. The petals ſpread open, not converging at their points, like thoſe of the firſt ſort. The corolla, ſtamens and nectaries, are of an elegant ſaffron colour.

[It differs little, according to Linneus, from the preceding, by its fulvous nectaries longer than the ſtamens, its deep yellow gaping corollas, and its germ or piſtils bent outwards, and as it were procumbent [o].

Native of Siberia. Cultivated by Mr. Miller in 1759. It flowers in may and june [p].]

PROPAGATION AND CULTURE.

1. Part the roots at the end of ſeptember, when the leaves are beginning to decay, planting them at a foot diſtance, in a ſhady ſituation and a moiſt ſoil. The plants ſhould not be parted oftener than once in three years, nor into parts too ſmall.

2. This may be increaſed and treated like the firſt, but requires a moiſter ſoil; it ſhould have a ſhady ſituation, but not under the drip of trees: it thrives beſt on a north border, where the ſoil is loamy, but not too ſtiff. In a dry ſoil, or much expoſed to the ſun, the plants frequently die in ſummer. It may be kept in a flouriſhing ſtate by covering the ſurface of the ground with moſs.

[Mr. Curtis adds, that it ſhould be planted in a compoſition of loam and bog earth, in a north border, taking care that it does not ſuffer from want of watering in dry ſummers. It may be raiſed from ſeeds, which frequently ripen on ſtrong healthy plants.]

As the flowers of both theſe plants make a pretty appearance, they deſerve a place in every good garden, eſpecially as they will thrive in moiſt ſhady places, where few better plants will live. By thus ſuiting plants to different ſoils and ſituations, every part of a garden may be well furniſhed, and a greater variety obtained.

Lin. ſpec. ed. Willd. 2. 299. *Lamarck encycl.* 1. 605. *t.* 277. *f.* 2.
Leaves quinate, leaflets quite entire acute, petals ſhorter than the calyx quite entire acute.]

DESCRIPTIONS, &c.

1. Stem herbaceous, trailing. Leaves almoſt circular, ſmooth, grayiſh. Flowers axillary, on very long peduncles; compoſed of five acute-pointed petals, the two upper large and rounded, the three under narrow jointed together at bottom and lengthened out into a tail two inches long. There are two varieties of this, one with a deep orange-coloured flower inclined to red, and the other with a pale yellow flower.

[This is diſtinguiſhed from the next by its ſmallneſs, and by the points at the top of the petals, and at the end of the nerves in the leaves. It was cultivated in 1596 by Gerarde, and was a great favourite with Parkinſon in 1629; but it was afterwards loſt in our gardens, till it was lately re-introduced by Dr. J. E. Smith, who by diſtributing it to his friends, and the nurſery-men near London, has again rendered it tolerably plentiful [q].] Mr. Miller (in 1768) ſays only it is leſs common at preſent in the Engliſh gardens than the ſecond.

Linneus ſays, it became known at Lima in 1580 by Dodonæus. That author informs us, that he ſaw this very rare foreign plant at Cologne, in the garden of Chriſtina Bertolf, widow of Joachin Hopper, and that ſhe had the ſeed from Spain.]

2. The ſecond ſort is larger in all its parts. The borders of the leaves are indented almoſt into lobes; and the petals are rounded at the top. There are two colours of this, as of the former, and alſo a variety with double flowers, as in that.

[The fruit conſiſts of three berries, (ſome conſider them rather as nuts),—becoming juiceleſs when ripe, fungous, deeply grooved and wrinkled, gibbous on one ſide, angular on the other, narrowing upwards,

[q] Curtis.

Digitized by Google

of a dirty white colour. Seeds ſolitary, of an oblong ſpheroidal form, but wrinkled by age, ſhaped as the berry is externally, rufeſcent, terminated at top by the umbilical chord[t].]

The flowers of this ſpecies being larger and making a finer appearance than thoſe of the preceding, was probably the reaſon why that was neglected, and for a time in a manner loſt to our gardens. They are both natives of Peru, and commonly eſteemed to be annual plants, though they may be continued through the winter, if they are kept in pots, and ſheltered in a green houſe or glaſs caſe, in like manner as the variety with double flowers is preſerved.

The ſtalks will climb ſix or eight feet high, when they are trained up, and thus the flowers make a good appearance; but when they trail upon the ground, they will ſpread over the neighbouring plants and become unſightly.

The flowers are frequently eaten in ſallads; they have a warm taſte like the garden Creſs, and hence the plant has its common name of Naſturtium; they are likewiſe uſed for garniſhing diſhes. The ſeeds are pickled, and by ſome are preferred to moſt pickles for ſauce, under the falſe name of capers.

[It begins to flower in july, and continues till the approach of winter.

Eliſabeth Chriſtina, daughter of the celebrated Linneus, we are informed by her father, obſerved the flowers of the great Indian Creſs to emit ſpontaneouſly, at certain intervals, ſparks like electric ones, viſible only in the evening, (ante crepuſculum.)

It is ſaid by Linneus to have been firſt brought into Europe by the care of Count Bewerning, in 1684.—If ſo, it quickly migrated into England, for according to Collinſon's manuſcripts, it was introduced in 1686 by Dr. Lumley Lloyd[u].

3. This agrees with the other Tropæolums in ſtature, ſize, &c. The leaves are different, not being peltate, but widely cuneate, nodding, moſtly five-lobed, with the lobes ſharpiſh; they are naked, nerved, veined, three times ſhorter than the petiole, with the whole margin aſcending, eſpecially the lateral one, which is ſo united to the oppoſite baſe, as to form there an almoſt cowled leaf, and the moſt ſlightly peltate of any. Nectary blunt. Corolla ſcarcely ever determinate. This plant took its riſe from the preceding at Stockholm, in the Ehrenreich garden, and can ſeldom be increaſed by ſeeds, but by ſlips or cuttings.

4. Root annual. Leaves ſlightly peltate, deeply five-cleft: the middle ſegment three-lobed, the next with a ſingle outer lobe. Petals ſcarcely longer than the calyx, ciliate-multifid. Tube of the calyx thickiſh, much longer than the corolla[x].

According to Willdenow, the petals are longer than the calyx, laciniated, ciliate and pale yellow.

Native of Peru. Introduced in 1775, by Benjamin Bewick, Eſq. It flowers in ſeptember and october[u].

5. Leaflets oval, ſubpetioled. All the petals ſeſſile and ſhort. Native of Monte Video[x].]

PROPAGATION AND CULTURE.

1, 2. Sow the ſeeds in april, in the places where they are to remain, which ſhould be where their ſtalks may have ſupport. The varieties with double flowers are continued by cuttings, and are kept under ſhelter all winter.

[The ſmaller ſort ſhould be raiſed on a hot-bed, like other tender annuals, if we wiſh to have it flower early in the ſummer, continue long in bloſſom, and produce perfect ſeeds. But it will grow readily in the open air, in warm ſheltered ſituations[y]. The greater ſort may alſo be brought forward in a hot-bed, if the flowers or fruit are wanted for uſe. But plants will come up ſpontaneouſly from ſeeds dropped in the autumn, which is rather extraordinary in a Peruvian plant.

β. Bucephalon racemoſum. *Lin. ſpec.* 2. 1661.

B. fructu racemoſo rubro. *Plum. gen.* 52. *ic.* 67.

DESCRIPTION, *&c.*

1. This is a tree twenty feet high at moſt, with nearly upright, round, even branches. Leaves oblong, acuminate with the point blunt, entire, beneath netted-veined and paler. Male flowers in peduncled roundiſh aments, an inch long, erect, axillary, ſubſolitary: flowers approximating, minute, whitiſh. Female flowers in axillary racemes, two together, longer than the petioles, compoſed of ſeven or eight ſeſſile, alternate, horizontal flowers. Germ pubeſcent: ſtyle parted to the baſe; ſegments length of the germ, ſpreading and bent down, with ferruginous hairs on them. The fruit is a ſtriated, one-ſeeded drupe. A clammy very white milky juice flows from an inciſion in the trunk of the tree, or from the branches when broken[z]. The leaves and twigs make an agreeable wholeſome fodder for all ſorts of cattle, and are often uſed as ſuch in dry ſeaſons, in the inland woody parts of Jamaica, where graſs is frequently very ſcarce. The berries (or drupes, as Swartz calls them) are generally about the ſize of large grapes, and of an agreeable pleaſant flavour[a].

Native not only of Jamaica, but of other iſlands in the Weſt Indies, in dry expoſed ſituations[b].

β. The leaves of this are ovate, acuminate, quite entire, alternate, on very ſhort petioles. Spikes lateral, ſolitary. Native of America[c]. Perhaps a different ſpecies.

Koenig found another ſpecies in the Eaſt Indies, which he named Trophis aſpera, or Rough-leaved Trophis. It is thus characterized and deſcribed by Sir William Jones in the fourth volume of the Aſiatic Reſearches.

MALE Flowers.

CAL. *Common* imbricated: *leaflets* ſix or eight, ovate, acute, ſmall, expanding, withering, containing generally from five to ſeven florets: *partial* four-parted; *diviſions* ovate, expanded, villous.

COR. none, unleſs you aſſume the calyx,

STAM. moſtly four (in ſome three, in one five.) *Filaments* awl-ſhaped, fleſhy, rather compreſſed, ſpreading over the diviſions of the calyx, and adhering to them at the point. *Anthers* double, folded.

The *buds* elaſtic, ſpringing open on a touch.

FEMALE Flowers.

CAL. four-parted; *diviſions* ovate, concave, pointed, permanent, propped by two ſmall *braƈtes*, unleſs you call them the calyx,

COR. none, unleſs you give the calyx that name.

PIST. *Germ* roundiſh. *Style* very ſhort, cylindric. *Stigma* long, two-parted, permanent.

[z] Swartz. [a] Browne. [b] Swartz. [c] Linn. ſpec.

PER,

Digitized by Google

PER. *Berry* one-ſeeded, navelled, ſmooth, ſomewhat flattened.
SEED globular, arilled.

Leaves various, ſome obovate, ſome oblong, ſome oval, pointed, irregularly notched, alternate (ſome oppoſite), crowded, criſp, very rough veined and paler beneath, ſmoother and dark above. Berry deep yellow. The Pandits having only obſerved the male plant, inſiſt that it bears no fruit. Female flowers axillary, from one to four or five in an axil.

On poor rocky ſoil it is low and buſhy, but in the plains it is a tree of conſiderable magnitude. From an idea of its aſtringent or antiſeptic virtue, the natives uſe little pieces of the wood, ſplit at one end into a kind of bruſh, for cleaning their teeth.

TUBER. See *Lycoperdon*.

Dr. Withering ſeparates the Lycoperdons that are more ſolid, ſtemleſs, do not become powdery, nor open at top, under this name of *Tuber*.

Dr. Withering names the eatable Truffle, (in ſome places called *Trubs*), *Tuber cibarium*. It is globular, the ſize of a large plumb, whitiſh, rugged with elevated dots, in the centre containing a brown powder like that of Lycoperdon Boviſta, but in ſmall quantity, opening with a rent[d]. It is found under the ſurface of the earth, at the depth of four or five inches. It has no proper root; the colour is dark approaching to blackneſs: when young it is white within, but when old black with whitiſh veins[e].

This is one of the beſt of the eſculent Fungi. Dogs are taught to hunt it; when they ſcent it, they bark a little, and begin to ſcratch up the earth. In Italy, they watch the pigs, who root it up. In England, it is found in high woods and paſtures, and on the downs of Wiltſhire, Hampſhire and Kent[f].

It is ſaid that Truffles may be cut by their eyes, like Potatoes, and propagated in the ſame manner. They delight in a clayey ſoil, and in ſhady places.

Nectary three-leaved.

DESCRIPTIONS, *&c*,

1. Stature of Galanthus or Snow drop. Root bulbous, with numerous thick ſubfuſiform fibres. Leaves radical, numerous, linear, even. Scape twice as long as the leaves. The ſpathe contains from five to ſeven flowers. Corolla green, like the oriental Hyacinth, with a ſmall acute border. Nectary very dark purple, length of the border[g].

Leaves almoſt filiform, ſomewhat fleſhy. Scape a foot high. Spathe umbelliferous, two-valved. Flowers drooping, duſky purple. Corolla one-petalled, tubular, gibbous at the baſe: border ſix-parted, with the parts linear obtuſe ſpreading length of the tube. Nectary placed at the mouth of the tube, ſix-toothed but very indiſtinctly, obtuſe, thick, length of the border. Filaments none: anthers ſix ſeſſile ovate twin, the three upper alternate, under the top of the nectary, the three lower in the nectary, below the others. Germ ſuperior: ſtyle ſhort: ſtigma ſimple, obtuſe. Capſule ovate, triangular, obtuſe, three-celled, three-valved. Seeds many, compreſſed, almoſt triangular[h].

Native of the Cape of Good Hope; where it flowers in auguſt.—Here it flowers in may; and was introduced in 1774, by Mr. Francis Maſſon[i].

2. Root bundled. Leaves radical, from two to four, lanceolate-linear, ſomewhat fleſhy. Scape a ſpan high. Spathe umbelliferous, two-valved. Flowers erect, purple. Corolla one-petalled, tubular, gibbous at the baſe: border ſix-parted, with the parts lanceolate, obtuſe, ſpreading, length of the tube. Anthers ſeſſile below the mouth of the tube; the three upper ones alternate. It differs from the firſt in being of ſmaller ſtature, and in having a three-

Stem many-flowered, many-leaved, leaves linear.

[k] Linn. ſuppl.

DESCRIPTIONS, *&c.*

1. Bulb ovate, gibbous. Stem quite ſimple, nearly upright, round, ſmooth, leafy in the middle, attenuated at the baſe. Leaves alternate, ſlightly embracing, lanceolate, acute, keeled, glauceſcent. Flower always yellow, greeniſh on the outſide. Petals elliptic-lanceolate, without any nectary. Filaments flatted. Anthers terminating, verſatile, oblong. Germ three-cornered. Stigma ſeſſile, three-cornered[l].

The wild Tulip has moſt of theſe characters in common with the garden ſpecies; but the circumſtances that abundantly diſtinguiſh this are the narrow leaves, the nodding flower, the hairineſs at the baſe of the ſtamens and on the tips of the petals, and eſpecially the ſimple obtuſe form of the ſtigma, which is totally different from that of the garden Tulip: the flower too is fragrant; the pollen yellow, not black; and the anthers remarkably long. In Flora Danica they are repreſented ſhort and round[m].

Leers remarks, that all the petals are villoſe at the tip, and the three inner ones at the baſe alſo. Desfontaines obſerves, that the petals are acute, the three outer ones narrower by half, and greeniſh on the outſide.

Native of the South of Europe, Germany and Switzerland; alſo of Siberia and Barbary. It was firſt given as a native or at leaſt a naturalized ſpecies, in Engliſh Botany, from the obſervations of W. Mathew, Eſq. who found it in an old chalk-pit near Bury; and on the opinion of Mr. Roſe of Norwich, and of Dr. Smith, who have both found it in a chalk-pit near that city. It has alſo been obſerved near Bury by Sir Thomas Gery Cullum, Bart. and at Whipſnade, on the borders of Hertfordſhire and Bedfordſhire, by the Rev. D. Jenks. It grows in a bed of good mould, above the chalk, the roots lying ſeveral inches below the ſurface, and flowers in april[n].

Linneus remarks, that the flower does not begin to open till about ten o'clock; whereas the garden Tulip opens before eight a. m. He reports, from Parkinſon, that the roots boiled, and eaten with oil and pepper, are ſapid and wholeſome: whereas Haller ſays they are acrid and cauſe vomiting.

According to the Kew catalogue, it was cultivated in 1597 by Gerarde.] Mr. Miller ſays, it was formerly preſerved in the Engliſh gardens, but ſince ſo many varieties of the third ſort have been propagated in England, that has been rejected, and is now only to be found in old neglected gardens.

[2. This is diſtinguiſhed both from the preceding and ſucceeding ſpecies, by its pubeſcent ſcape, ſpreading ſweet-ſmelling corolla, the earlineſs of its flowering, and the ſmallneſs of its ſize. Native of the South of Europe[o].

3. Stem nearly upright or bending a little, taller and ſtronger than in the firſt, from a foot to eighteen inches in height. Leaves three, four or five, embracing, doubled, lanceolate, acute, nerved, glaucous; the loweſt near the bulb two inches and a half wide, the others gradually narrower. Flower large, erect, in a wild ſtate, moſt commonly ſtained with a black baſe; petals ovate, blunt, ſmooth. Anthers commonly very dark-coloured or black. Stigma three-lobed, each lobe bifid, bent back, and the edge curled back.—Capſule ſuperior, of a triangular priſmatic form, three-grooved, tranſverſely ſtriated: valves having a partition in the middle, and ciliate at the ſutures with white ſilky vibriſſæ turned inwards. Seeds obovate, narrowed towards the navel, flat on both ſides, margined, ruſeſcent, faſtened horizontally in a double row to the central margin of the partitions. Before the fruit is fully ripe, the vibriſſæ in this genus, and in that of Fritillaria, are glued together into three thin membranes, which being interpoſed between the columns of ſeeds, make the unripe capſules ſix-celled[p].

Native of many parts of the Levant. Linneus (from Geſner) ſays, Cappadocia, whence it came to Europe in 1559. It is common in Syria, and is ſup-

poſed by ſome to be the lily of the field alluded to by our Saviour. In Perſia, where it is abundant, they conſider it as the emblem of perfect lovers. When a young man, ſays Chardin, preſents one to his miſtreſs, he gives her to underſtand, by the general colour of the flower, that he is on fire with her beauty, and by the black baſe of it, that his heart is burnt to a coal. Chardin ſaw it on the northern confines of Arabia. Rauwolff found it at Aleppo, and on mount Libanus; Shaw, between Jaffa and Rama; Buſbequius, between Adrianople and Conſtantinople, every where in abundance, with Narciſſus, Hyacinths, &c. in the middle of winter. It grows alſo in Macedonia, Thrace, and the Crimea. According to Cluſius, the early-blowing flowers were brought to Conſtantinople from Cavala, a town on the eaſtern coaſt of Macedonia; and the late-blowing ones, from Caffa, a town in the Crimea.

Conrad Geſner firſt made the eaſtern Tulip known by a deſcription and figure. In his additions to Cordus, he tells us that he firſt ſaw it in the beginning of april 1559 at Augſbourg, in the garden of John Henry Harwart. The ſeeds were brought from Conſtantinople, or according to others from Cappadocia. Balbinus aſſerts, that Buſbequius brought the firſt Tulip roots to Prague, whence they were ſpread all over Germany. Buſbequius himſelf ſays, in a letter written 1554, that this flower was then new to him. We know that he collected natural curioſities, and brought many from the Levant. He relates that he paid very dear to the Turks for Tulips; but he no where affirms that he was the firſt who brought them from the Eaſt. In 1565, there were Tulips in the garden of Mr. Fugger, from whom Geſner wiſhed to procure ſome [q].

Cluſius informs us, that Augerius de Buſbeque (Buſbequius) received a great quantity of the ſeed, together with many bulbs, from Conſtantinople, the year that Cluſius came to Vienna, and going the year following to France, he left them under the care of Cluſius, who in 1575 and the following year, committed them to the ground in a heap, thinking they were ſo old and withered that they would not come to any thing; they grew however, and produced a great variety of flowers.

Cluſius relates alſo that he gave more than a hundred bulbs to an apothecary at Vienna to be preſerved in ſugar, in the ſame manner as the roots of the Orchis, with a view to aſcertain whether they had not the ſame qualities, but he neglected the buſineſs. However in the year 1592, John Muler, another apothecary, preſerved a quantity of the roots, and they were found to be far more ſweet and pleaſant than Orchis roots, but whether they had the ſame virtues was not aſcertained. A merchant of Antwerp had a cargo of the roots thirty years before this (1562), and taking them for a ſort of onion, ordered ſome to be roaſted under embers, and ate them with oil and vinegar like common onions: the reſt he ſet in the kitchen garden among the cabbages, where moſt of them periſhed, except a few that George Rye, a merchant of Mecklin took under his care, and which produced a variety of beautiful flowers.

According to the Kew catalogue the Tulip was cultivated in England, by Mr. James Garret, in 1577. Reference is made to Gerarde's herbal, publiſhed in 1597: where it is ſaid—"my loving friend Maſter "James Garret, a curious ſearcher of ſimples, and "learned apothecary in London, hath undertaken to "find out if it were poſſible, the infinite ſorts, by "diligent ſowing of their ſeeds, and by planting thoſe "of his own propagation, and by others received "from his friends beyond the ſeas, for the ſpace of "*twenty* years not being yet able to attain to the "end of his travaile, for that each new year bringeth "forth new plants of ſundry colours not before ſeen: all "which to deſcribe particularly were to roll Siſyphus "ſtone, or number the ſands." Gerarde ſays alſo, that he received it from Aleppo, and he mentions Maſter Garth, a worſhipful gentleman, as a cultivator of this bulb.

This era of the introduction of the Tulip into England is confirmed by the remembrances for Maſter S. by Richard Hakluyt, in 1582, wherein it is ſaid, —"now within theſe four years there have been "brought in England, from Vienna in Auſtria, divers "kinds of flowers called Tulipas."

They firſt appeared in Provence, in the garden of the celebrated Peyreſc.

Towards the middle of the ſeventeenth century the Tulip became the object of a conſiderable trade, and the price of the roots roſe higher than that of the moſt precious metals. It was chiefly carried on in ſome cities of the Netherlands, and roſe to its greateſt height in 1634 and the three following years. For one root of a variety called the *Viceroy*, articles to the value of 2500 florins were agreed to be delivered. The *Semper Auguſtus* has been often ſold for 2000 florins: one perſon agreed to give 4600 florins, with a new carriage, two horſes and complete harneſs; and another agreed to give twelve acres of land for a ſingle root. The trade was generally followed for a time, but it was a mere gambling buſineſs, like the Miſſiſippi and South ſea ſchemes, and was rightly named *Tulipomania* [r].

No plant affords more varieties than the Tulip. Sometimes, but rarely, it has two flowers; ſix petals is the regular number, but it is not uncommon to find ſeven or eight, and the flowers are ſometimes quite double; ſome of the varieties produce their flowers earlier than others; and the capſules are not very unfrequently four-ſided and four-celled. But the moſt remarkable variation in the Tulip is in the colours of the petals, an almoſt infinite variety of theſe having been produced by art.

The old authors divided Tulips into *Præcoces* or early-blowers, and *Serotinæ* or late-blowers, with an intermediate diviſion of *Dubiæ Mediæ*, doubtful or middle-blowers, which flowered between the two others, and for the moſt part rather belonged to the late-blowers. Modern floriſts have almoſt neglected the early-blowers.

Theſe are not near ſo fair, ſays Mr. Miller, nor do they riſe half ſo high as the late ones; but they are chiefly valued for appearing early in the ſpring: ſome of them will flower the middle of march in mild ſeaſons, if planted in a warm border near a wall or other ſhelter, and others will ſucceed them, ſo that they will keep flowering until the general ſeaſon for theſe flowers is come, which is towards the end of april. As theſe early-blowers are few in compariſon with the others, Mr. Miller gives the names of the principal ones, to the number of forty-one. By thoſe names the roots were to be obtained in Flanders and Holland, where the floriſts are very exact in keeping up their liſts of flowers complete.

The ſeveral varieties of theſe early-blowing Tulips riſe to different heights in their ſtems, and ſcarcely any two of them are equal. The Duke Van Toll, which is one of the firſt that appears in the ſpring, is generally very ſhort-ſtalked, and the others in proportion to their earlineſs are ſhorter than thoſe which ſucceed them; and the late-blowers are all conſiderably longer in their ſtems than any of the early-blowers, ſo that when they are mixed together confuſedly, they make a very indifferent appearance.

The late-blowing Tulips producing much finer flowers than the early ones, have engroſſed almoſt the whole attention of the floriſts. It would be to little purpoſe to enumerate all the varieties, ſince there is ſcarcely any end of their numbers, and what ſome value at a conſiderable rate, others reject; and as there are annually many new flowers obtained from breeders, thoſe which are old, if they have not very good properties to recommend them, are thrown out and deſpiſed.

[Parkinſon, ſo long ſince as 1629, enumerates 140 varieties in his Paradiſus terreſtris. But to tell you

[r] Beckmann.

of

of all the ſorts, ſays he, which are the pride of delight, they are ſo many, and as I may ſay, almoſt infinite, doth both paſs my ability, and as I believe, the ſkill of any other. There is ſuch a wonderful variety and mixture of colours in them, that it is almoſt impoſſible for the wit of man to decipher them thoroughly, and to give names that may be true, and ſeveral diſtinctions to every flower. Threeſcore ſeveral ſorts of colours ſimple and mixed I can reckon up that I have, and of eſpecial note, and yet I doubt not, but for every one of them there are ten others differing from them. But beſides this glory of variety in colors that theſe flowers have, they carry ſo ſtately and delightful a form, and do abide ſo long in their bravery, that there is no lady or gentlewoman of any worth that is not caught with this delight.

In Parkinſon's time the early-blowers, and doubtful or mean-flowering Tulipas, as he calls them, furniſhed moſt of the varieties: the ſerotina or late-flowering Tulipa, as he ſays, having no ſuch plentiful variety of colours or mixtures in his flowers, as are in the two former ſorts. Accordingly he enumerates only five varieties of theſe, which now furniſh the Floriſts with all thoſe beauties which attract their admiration. But probably many which he calls meane (that is, intermediate) flowering, are properly late-blowers. He divides the flowers into their four primary or principal colours, white, purple, red and yellow; and under every one of theſe, ſets down the ſeveral mixtures which he has ſeen and obſerved in them.

Modern Floriſts in Holland and Flanders, and our Engliſh Floriſts from them, boaſt a prodigious variety of late-blowing Tulips. Mr. Maddock of Walworth, in his catalogue of flowers for 1792, has no leſs than about 665 of theſe admired beauties, all ranged under their proper families and colours, with their names and prices: beſides the early ſorts, double tulips, parrot-tulips, french tulips; and breeders.

The late-blowers are diſtributed into five families. 1. Primo Baguets: very tall; fine cups with white bottoms, well broken with fine brown, and all from the ſame breeder. 2. Baguet Rigauts: not quite ſo tall, but with ſtrong ſtems, and very large well-formed cups with white bottoms, well broken with fine brown, and all from the ſame breeder. 3. Incomparable Verports: a particular kind of Bybloemens; with moſt perfect cups; very fine white bottoms; well broken with ſhining brown; and all from the ſame breeder. Some of theſe are from two to five guineas a root. 4. Bybloemens: with bottoms white or nearly ſo, from different breeders, and broken with variety of colours. Thoſe of the Verports are cherry and roſe. 5. Bizarres: ground yellow; from different breeders, and broken with variety of colours.—Theſe barbarous terms uſed by the Dutch Floriſts, are a mixture of Dutch and French. Baguet, is from the French Baguette, a rod or wand, ſo named from its tall ſlender ſtem. Bizarre is alſo French; and the Tulips of that family have the name from the variety and irregularity of their colours. Rigauts are probably from the name of ſome eminent floriſt, Rigaud. The other terms are Dutch.—Breeders are of one colour, and when broken produce new varieties.

The properties of a fine variegated late Tulip, according to the beſt modern Floriſts are theſe. 1. The ſtem ſhould be ſtrong, upright, and tall, about thirty inches high. 2. The flower ſhould be large, compoſed of ſix petals, proceeding a little horizontally at firſt, and then turning upwards ſo as to form an almoſt perfect cup with a round bottom, rather wider at the top. 3. The three outer petals ſhould be rather larger than the three inner ones, and broader at their baſe: all the petals ſhould have the edges perfectly entire; the top of each ſhould be broad and well rounded; the ground colour at the bottom of the cup ſhould be clear white or yellow; and the various rich ſtripes, which are the principal ornament of a fine flower, ſhould be regular, bold, and diſtinct on the margin, and terminate in fine broken points, elegantly feathered or pencilled. 4. The centre of each petal ſhould contain one or more bold blotches or ſtripes, intermixed with ſmall portions of the original colour, abruptly broken into many irregular obtuſe points. Some Floriſts are of opinion that the central ſtripes or blotches do not contribute to the beauty of the Tulip, unleſs they are confined to a narrow ſtripe exactly down the centre; and that they ſhould be perfectly free from any remains of the original colour; it is certain that ſuch flowers appear very beautiful and delicate, eſpecially when they have a regular narrow feathering at the edge: but it is unanimouſly agreed, that the Tulip ſhould abound in rich colouring, diſtributed in a diſtinct and regular manner throughout the flower, except in the bottom of the cup, which ſhould indiſputably be of a clear bright white or yellow, free from ſtain or tinge, in order to conſtitute a perfect flower[1].

The double and Parrot Tulips are in no ſort of eſteem among the Floriſts.

4. Plant the ſize of Ornithogalum luteum. Stem very ſmooth. Leaves two alternate linear attenuated to both ends recurved channelled, ſheathing the ſtem at bottom. Peduncles ſhorter than the leaves two or three in a ſort of umbel. Flowers like thoſe of Ornithogalum luteum, but ſeveral times bigger and ſpreading. The three outer petals lanceolate, pale ſky-blue or greeniſh; the inner ones white with a large orange ſpot at the baſe. Filaments bearded at the baſe. The bulb every year drops down perpendicularly a little bulb, which ſucceeds the old one.

Native of Ruſſia, by the Wolga[2].

5. Stem-leaves ſix or ſeven alternate, linear, lanceolate, the upper ones gradually ſhorter. Flowers at the top, three or four, ſmaller than in Breynius's cultivated plant. Petals narrowed at the baſe. Style none. Native of the Cape of Good Hope[3]. Introduced in 1787, by Mr. Francis Maſſon. It flowers in july[4].]

PROPAGATION AND CULTURE.

3. The roots of early blowing Tulips ſhould be planted the beginning of September, in a warm border, near a wall, pale, or hedge; becauſe if they are put into an open ſpot of ground, their buds are in danger of ſuffering by morning froſts in the ſpring. The ſoil for theſe ſhould be renewed every year, where people intend to have them fair. The beſt ſoil for this purpoſe is that which is taken from a light ſandy paſture, with the turf rotted amongſt it, and to this ſhould be added a fourth part of ſea ſand. This mixture may be laid about ten inches deep, which will be ſufficient for theſe roots, which need not be planted more than four or five inches deep at moſt. The offſets ſhould not be planted amongſt the blowing roots, but in a border by themſelves, where they may be planted pretty cloſe together, eſpecially if they are ſmall; but theſe ſhould be taken up when their leaves decay, in the ſame manner as the blowing roots, otherwiſe they would rot if the ſeaſon ſhould prove very wet; for theſe are not ſo hardy as the late blowers, nor do they increaſe half ſo faſt as thoſe, ſo that a greater care is required to preſerve the offsets of them. When theſe Tulips come up in the ſpring, the earth upon the ſurface of the borders ſhould be gently ſtirred and cleared from weeds; and as the buds appear, if the ſeaſon ſhould prove very ſevere, it will be of great ſervice to cover them with mats, for want of which many times they are blighted, and their flowers decay before they blow, which is often injurious to the roots, as is alſo the cropping of the flowers ſo ſoon as they are blown; becauſe their roots, which are formed new every year, are not at that time arrived to their full magnitude, and are hereby deprived of proper nouriſhment.

If, when theſe flowers are blown, the ſeaſon ſhould prove very warm, it will be proper to ſhade them with mats, &c. in the heat of the day; as alſo if the nights are froſty, they ſhould be in like manner covered, whereby they may be preſerved a long time in beauty; but, when their flowers are decayed, and their ſeed-veſſels begin to ſwell, they ſhould be broken off juſt at the top of the ſtalks, becauſe if they are permitted to ſeed, it will injure the roots.

Digitized by Google

When the leaves of theſe flowers are decayed (which will be before the late blowers are out of flower) their roots ſhould be taken up, and ſpread upon mats in a ſhady place to dry; after which they ſhould be cleared from their filth, and put in a dry place where the vermin cannot come to them, until the ſeaſon for planting them again, being very careful to preſerve every ſort ſeparate, that you may know how to diſpoſe of them at the time for planting; becauſe it it is the better way to plant all the roots of each ſort together (and not to intermix them, as is commonly practiſed in moſt other kinds of flowers;) for as there are few of them which blow at the ſame time, ſo when the ſeveral roots of one ſort are ſcattered through a whole border, they make but an indifferent appearance; whereas, when twenty or thirty roots of the ſame ſort are placed together, they will all flower at the ſame time, and afford a more agreeable appearance.

There are many curious perſons, who, in order to preſerve their ſeveral kinds of Tulips, and other bulbous-rooted flowers ſeparate, have large flat boxes made, which are divided into ſeveral parts by ſmall partitions, each of which is numbered in the ſame manner as the diviſions of their beds; ſo that when a catalogue of their roots is made, and the numbers fixed to each ſort in the beds, there is nothing more to do when they take up their roots, but to put every kind into the diviſion marked with the ſame number which was placed to each ſort in the bed, which ſaves a great deal of trouble in making freſh marks every time the roots are taken up, and effectually anſwers the purpoſe of preſerving the kinds ſeparate.

The late blowing Tulips are generally obtained from breeders, which is a term applied to all ſuch flowers as are produced from ſeeds, which are of one ſelf-colour, and have good bottoms and chives; theſe in time break into various beautiful ſtripes, according to the ground of their former ſelf-colour, but this muſt be entirely thrown off, otherwiſe they do not eſteem a flower well broken.

Of theſe breeders there has been a great variety brought into England from Flanders which is the grand nurſery for moſt ſorts of bulbous-rooted flowers; but there are ſome curious perſons, who have lately obtained many valuable breeders from ſeed ſown in England; and doubtleſs, were we as induſtrious to ſow the ſeeds of theſe flowers as the people of France and Flanders, we might in a few years have as great a variety as is to be found in any part of Europe; for, although it is ſix or ſeven years from the ſowing before the flowers blow; yet, if after the firſt ſowing there is every year a freſh parcel ſown, when the ſeven years are expired, there will be conſtantly a ſucceſſion of roots to flower every year, which will reward the expectation, and keep up the ſpirit of raiſing; but it is the length of time at firſt, which deters moſt people from this work.

The manner of propagating theſe flowers from ſeeds is as follows: you ſhould be careful in the choice of the ſeed, without which there can be little ſucceſs expected. The beſt ſeed is that which is ſaved from breeders which have all the good properties before related, for the ſeeds of ſtriped flowers ſeldom produce any thing that is valuable.

The beſt method to obtain good ſeeds is to make choice of a parcel of ſuch breeding Tulip roots as you would ſave ſeeds from, and place them in a ſeparate bed from the breeders, in a part of the garden where they may be fully expoſed to the ſun, obſerving to plant them at leaſt nine inches deep; for if they are planted too ſhallow, their ſtems are apt to decay before their ſeed is perfected.

Theſe flowers ſhould always be expoſed to the weather, for if they are ſhaded with mats, or any other covering, it will prevent their perfecting the ſeed. About the middle of july, (a little ſooner or later, as the ſummer is hotter or colder) the ſeeds will be fit to gather, which may be known by the dryneſs of their ſtalks, and the opening of the ſeed-veſſels, at which time they may be cut off, and the ſeeds preſerved in the pods till the ſeaſon for ſowing, being careful to put them up in a dry place, otherwiſe they will be ſubject to mould, which will render them good for little.

Having ſaved a parcel of good ſeed, about the beginning of September is the beſt ſeaſon for ſowing it, when there ſhould be provided a parcel of ſhallow ſeed-pans, or boxes, which ſhould have holes in their bottoms to let the moiſture paſs off; theſe muſt be filled with freſh ſandy earth, laying the ſurface very even, upon which the ſeeds ſhould be ſown as regularly as poſſible, that they may not lie upon each other; then there ſhould be ſome of the ſame light ſandy earth ſifted over them, about half an inch thick. Theſe boxes or pans ſhould be placed where they may have the morning ſun till eleven of the clock, in which ſituation they may remain until october, at which time they ſhould be removed into a more open ſituation, where they may enjoy the benefit of the ſun all the day, and be ſheltered from the north winds, where they ſhould remain during the winter ſeaſon; but in the ſpring, when the plants are up, they ſhould be again removed to their firſt ſituation; and if the ſeaſon ſhould be dry, they muſt be refreſhed with water while the plants remain green; but as ſoon as their tops begin to decay, there muſt be no more given them, leſt it rot their tender bulbs; therefore the boxes ſhould be placed in a ſhady ſituation during the ſummer ſeaſon, but not under the drip of trees.

Theſe plants, at their firſt appearance, have very narrow graſſy leaves like thoſe of onions, and come up with bending heads, in the ſame manner as they do; ſo that perſons who are unacquainted with them, may pull them up inſtead of graſs whilſt they are very young, before their leaves are a little more expanded, which is rarely performed the firſt year; for they ſeldom appear before the middle of march, and they commonly decay about the latter end of may, or the beginning of june, according as the ſeaſon is hotter or colder.

The weeds and moſs ſhould alſo be cleared off from the ſurface of the earth in the boxes, and a little freſh earth ſifted over them ſoon after their leaves decay, which will be of great ſervice to their roots. Theſe boxes ſhould be conſtantly kept clear from weeds, which, if permitted to grow therein, when they are pulled up, the roots will be apt to draw the bulbs out of the ground. At michaelmas they ſhould be freſh earthed again, and as the winter comes on, they muſt be again removed into the ſun as before, and treated in the ſame manner, until the leaves decay in the ſpring, when the bulbs ſhould be carefully taken up, and planted in beds of freſh ſandy earth, which ſhould have tiles laid under them, to prevent their roots from ſhooting downward, which they often do when there is nothing to ſtop them, and thereby are deſtroyed. The earth of theſe beds ſhould be about five inches thick upon the tiles, which will be ſufficient for nouriſhing theſe roots while they are young.

The diſtance which theſe young bulbs ſhould be allowed, need not be more than two inches, nor ſhould they be planted above two inches deep; but toward the end of october, it will be proper to cover the beds over with a little freſh earth about an inch deep, which will preſerve the roots from the froſt, and prevent moſs or weeds from growing over them; but, if the winter ſhould be very ſevere, it will be proper to cover the bed either with mats or peas-haulm, to prevent the froſt from entering the ground, becauſe theſe roots are much tenderer while young, than they are after they have acquired ſtrength.

In the ſpring the ſurface of the ground ſhould be gently ſtirred to make it clean, before the plants come up; and if the ſpring ſhould prove dry, they muſt be frequently refreſhed with water during the time of their growth; but this muſt not be given to them in great quantities, leſt it rot their tender bulbs; and when the leaves are decayed, the weeds ſhould be taken off, and the beds covered with freſh earth, which ſhould alſo be repeated again in autumn.

In theſe beds the bulbs may remain two years, during which time they muſt be conſtantly kept clear from weeds, and in ſpring and autumn freſh earthed, in the manner already directed; after which the bulbs

Digitized by Google

must be taken up, and planted into freſh beds, at four inches aſunder, and as many deep, where they may remain two years more, during which time they ſhould have the ſame culture as before; and after that, the bulbs being large enough to blow, they ſhould be taken up, and planted in freſh beds at the uſual diſtance, and in the ſame manner as old roots; where, when they flower, ſuch of them as are worthy to be preſerved, ſhould be marked with ſticks; and at the ſeaſon for taking up the bulbs, they muſt be ſeparated from the others, in order to be planted as breeders in different beds; but you ſhould by no means throw out the reſt until they have flowered two or three years, becauſe it is impoſſible to judge exactly of their value in leſs time; for many, which at firſt flowering appear beautiful, will afterwards degenerate ſo as to be of little value; and others, which did not pleaſe at firſt, will many times improve, ſo that they ſhould be preſerved until their worth can be well judged of.

In this method many ſorts of new breeders will be annually raiſed, from which there will always be fine flowers broken, which, being the produce of a perſon's own ſowing, will be greatly valued, becauſe they are not in other hands, which is what enhances the price of all flowers: and it has been entirely owing to this method of raiſing new flowers, that the Dutch have been ſo famous, amongſt whom the paſſion for fine Tulips did ſome time reign ſo violently, that many of the floriſts near Haerlem have often given a hundred ducats for one ſingle root; which extravagance was the occaſion of an order being made by the States, to limit the utmoſt price that ſhould be afterward given for any Tulip root, were it ever ſo fine.

Having thus given an account of the method of raiſing theſe flowers from ſeeds, I ſhall now proceed to the management of thoſe roots which are termed breeders, ſo as to have ſome of them every year break out into fine ſtripes.

There are ſome who pretend to have a ſecret how to make any ſort of breeders break into ſtripes whenever they pleaſe, but this, I dare ſay, is without foundation; for from many experiments which I and others have made of this kind, I never could find any certainty of this matter. All that can be done by art, is to ſhift the roots every year into freſh earth of different mixtures, and into a different ſituation, by which method I have had very good ſucceſs.

The earth of theſe beds ſhould be every year different, for although it is generally agreed that lean, hungry, freſh earth haſtens their breaking, and cauſes their ſtripes to be the finer and more beautiful, yet, if they are every year planted in the ſame ſort of ſoil, it will not have ſo much effect on them, as if they were one year planted in one ſort of earth, and the next year in a very indifferent one, as I have ſeveral times experienced; and if ſome fine ſtriped Tulips are planted in the ſame beds with the breeders, intermixing them together, it will alſo cauſe the breeders to break the ſooner.

The beſt compoſt for theſe roots is a third part of freſh earth from a good paſture, which ſhould have the ſward rotted with it, a third part of ſea ſand, and the other part ſifted lime rubbiſh; theſe ſhould be all mixed together ſix or eight months at leaſt before it is uſed, and ſhould be frequently turned, in order to mix the parts well together. With this mixture the beds ſhould be made about two feet deep, after the following manner: after the old earth is taken from out of the bed to the depth intended, then ſome of the freſh earth ſhould be put in about eighteen inches thick; this ſhould be levelled exactly, and then lines drawn each way of the bed, chequerwiſe; at ſix inches diſtance, upon the center of each croſs, ſhould be placed the Tulip roots, in an upright poſition, and after having finiſhed the bed in this manner, the earth muſt be filled in, ſo as to raiſe the bed ſix or eight inches higher, obſerving, in doing this, not to diſplace any of the roots, and alſo to lay the top of the beds a little rounding to throw off the water.

There are many perſons who are ſo careleſs in planting their Tulip roots, as only to dig and level the beds well, and then with a blunt dibble to make holes, in-

to which they put the roots, and then fill up the holes with a rake, but this is by no means a good method; for the dibble, in making the holes, preſſes the earth cloſely on each ſide, and at the bottom, whereby the moiſture is often detained ſo long about the roots as to rot them, eſpecially if the ſoil is inclinable to bind; beſides the earth being hard at the bottom of the bulbs, they cannot ſo eaſily emit their fibres, which muſt certainly prejudice the roots.

Theſe beds ſhould be ſunk, more or leſs, below the ſurface, according to the moiſture or dryneſs of the ground, for the roots ſhould be ſo elevated as neve to have the water ſtand near the reach of their fibre in winter, for moiſture is very apt to rot them; ſo that where the ſoil is very wet, it will be proper to lay ſome lime rubbiſh under the earth, in order to drain off the wet, and the beds ſhould be entirely raiſed above the level of the ground; but to prevent their falling down into the walks, after froſt or hard rains, it will be proper to raiſe the paths between them, either with ſea coal aſhes or rubbiſh, eight or ten inches, which will ſupport the earth of the beds; and theſe paths may ſlope at each end from the middle, which will make paſſage for the water to run off as it falls. But where the ſoil is dry, the bottom of the beds may be ſunk eighteen or twenty inches below the ſurface, for in ſuch places the beds need not be more than four or ſix inches above the ſurface, which will be allowance enough for their ſettling.

During the winter ſeaſon there will be no farther care required. The roots being planted thus deep, will be in no danger of ſuffering by ordinary froſts, but if the winter ſhould prove very ſevere, ſome rotten tan or peas-haulm may be laid over the beds to keep out the froſt during the continuance, but this muſt be removed when the froſt is over; and in the ſpring, when their leaves begin to appear above ground, the earth upon the ſurface of the beds ſhould be ſtirred to clear it from weeds, moſs, &c. and when the flower-buds begin to come up, they ſhould be guarded from froſt, otherwiſe they are very ſubject to blight and decay ſoon after they appear, if the froſt pinches their tops; but they need only be covered in ſuch nights when there is a proſpect of froſt, for at all other times they ſhould have as much air as poſſible, without which they will draw up weak, and produce ſmall flowers.

When the breeding Tulips are in flower, you ſhould carefully examine them, to ſee if any of them have broken into beautiful ſtripes, which, if you obſerve, there ſhould be a ſtick put into the ground by every ſuch root, to mark them, that they may be ſeparated from the breeders, to plant amongſt the ſtriped flowers the following year; but you ſhould carefully obſerve, whether they have thrown off their former colour entirely, as alſo when they decay, to ſee if they continue beautiful to the laſt, and not appear ſmeared over with the original colour, in both which caſes they are very ſubject to go back to their old colour the next year: but if their ſtripes are diſtinct and clear to the bottom, and continue ſo to the laſt, (which is what the floriſts call dyeing well,) there is no great danger of their returning back again, as hath been by ſome confidently reported; for if one of theſe flowers is quite broken (as it is termed,) it will never loſe its ſtripes, though ſometimes it will blow much fairer than at others, and the flowers of the offsets will be often more beautiful than thoſe of the old roots.

This alteration in the colour of theſe flowers may be ſeen long before they are blown, for all the green leaves of the plant will appear of a fainter colour, and ſeem to be ſtriped with white, or of a browniſh colour, which is a plain proof, that the juices of the whole plant are altered, or, at leaſt, the veſſels through which the juice is ſtrained; ſo that hereby particles of a different figure are capable of paſſing through them, which, when entered into the petals of the flower, reflect the rays of light in a different manner, which occaſions the variety we ſee in the colours of flowers. This breaking of the colours in flowers proceeds from weakneſs, or at leaſt is the cauſe of weak-

Digitized by Google

neſs in plants; for it is obſervable, that after Tulips are broken into fine ſtripes, they never grow ſo tall as before, nor are the ſtems, leaves, or flowers, ſo large as before; and it is the ſame in all other variegated plants and flowers whatever, which are alſo much tenderer than they were before they were ſtriped; ſo that many ſorts of exotic plants which by accident became variegated in their leaves, are often rendered ſo tender, as not to be preſerved without much more care, though indeed the ſtriping of Tulips never occaſions ſo great weakneſs in them as to render them very tender. The greateſt effect it has on them, is in leſſening their growth, cauſing ſome (which, while they continued in their original plain colours, roſe near three feet in height) to advance little more than two after their colours were altered; and the more beautifully their ſtripes appear, the ſhorter will be their ſtems, and the weaker their flowers.

There is nothing more to be obſerved in the culture of ſtriped flowers than what has been directed for breeders, excepting that theſe ſhould be arched over with tall hoops and rails, that they may be ſhaded from the ſun in the day time, and protected from ſtrong winds, hard rains, and froſty mornings, otherwiſe the flowers will continue but a ſhort time in beauty; but where the inſtructions here given are duly followed, they may be preſerved in flower a full month, which is as long as moſt other flowers continue.

There are ſome perſons who are ſo extremely fond of theſe flowers, as to be at a great expenſe in erecting large frames of iron work to cover their beds of Tulips, in ſuch a manner, that they may walk between two beds under the frames, over which are ſpread tarpaulins, ſo as to keep off ſun, rain, and froſt, whereby they can view the flowers without being at the trouble of taking off or turning up the tarpaulins, or being incommoded by the ſun or rain, which cannot be avoided where the covering is low; beſides, by thus raiſing the covers, the flowers have a greater ſhare of air, ſo that they are not drawn ſo weak, as they are when the covering is low and cloſe to them; but theſe frames being expenſive, can only be made by perſons of fortune; however, there may be ſome of wood contrived at a ſmaller expense, which being arched over with hoops, may anſwer the purpoſe as well as the iron frames, though they are not ſo ſightly or laſting.

But after the flowers are faded, the heads of all the fine ſorts ſhould be broken off to prevent their ſeeding; for if this is not obſerved, they will not flower near ſo well the following year, nor will their ſtripes continue ſo perfect; and this will alſo cauſe their ſtems to decay ſooner than otherwiſe they would do, ſo that their roots may be taken up early in june, for they ſhould not remain in the ground after their leaves are decayed. In taking the roots out of the ground, you muſt be very careful not to bruiſe or cut them, which will endanger their rotting, and, if poſſible, it ſhould be done a day or two after rain. When theſe roots are taken out of the ground, they muſt be cleared from their old covers, and all ſorts of filth, and ſpread upon mats in a ſhady place to dry, after which they ſhould be put up in a dry place, where vermin cannot get to them, obſerving to keep every ſort ſeparate, but they ſhould not be kept too cloſe from the air, nor ſuffered to lie in heaps together, leſt they ſhould grow mouldy, for if any of the roots once take the mould, they commonly rot when they are planted again, if not before.

The offsets of theſe roots, which are not large enough to produce flowers the ſucceeding year, ſhould be alſo put by themſelves, keeping each ſort diſtinct; theſe ſhould be planted a month earlier in autumn than the blowing roots, in particular beds by themſelves in the flower-nurſery, where they may not be expoſed to public view; but the earth of the beds ſhould be prepared for them in the ſame manner as for larger roots, though theſe ſhould not be planted above five inches deep, becauſe they are not ſtrong enough to puſh through ſo great covering of the earth as the old roots; they may be placed much nearer together than thoſe which are to flower, and in one year moſt of them will become ſtrong enough to flower, when they may be removed into the flower-garden, and placed in the beds amongſt thoſe of the ſame kinds.

[The moſt proper time to plant Tulip roots is from the end of october to the tenth of november. The bed ſhould be in an open airy part of the garden. Having marked out the ground according to the intended dimenſions of the bed, take out the ſoil to the depth of twenty inches: fill up the bottom with ſound freſh earth, ten inches thick; upon this put a mixture of rotten cow-dung and freſh earth in equal quantities and two years old, to the thickneſs of twelve inches; and upon this more of the ſame kind of earth as that of the bottom, two inches thick at the ſides, and three in the middle, to give the bed a ſmall degree of convexity. This operation is to be performed about the 20th of october, or a week or two before planting, that the bed may have time to ſettle. It will then be about two inches higher than the alleys. If heavy rains ſhould intervene, it will be proper to cover the bed to keep them off; becauſe they would render it too compact and adheſive for the tender fibres to paſs freely through it.

On the day of planting, rake the ſurface of the bed even, ſtill preſerving its convexity, and mark the places for the roots ſeven inches from each other every way. Adapting the length of the bed, and the number of rows to the quantity of your roots.

If the bed conſiſts of ſeven rows, which makes the handſomeſt appearance, it ſhould be fifty inches wide, which will allow a ſpace of four inches between the outer rows and the ſides of the bed; and there ſhould be an alley or path round it two feet and an half or three feet wide. If the bed ſhould contain only five rows, it muſt be three feet wide to give the roots the ſame diſtances. Such a bed will require only one path in front.

Having ſprinkled a little clean ſand where the roots are to be ſet, place them with great exactneſs, and add ſome very ſandy earth, ſo as to envelope each root completely in a little cone of it; then cover the whole very carefully with ſtrong ſound freſh loam, about four inches thick at the middle of the bed, gradually decreaſing to three inches at the ſides: thus will the convexity be increaſed in a proper degree, and the roots will be covered with ſoil proportioned to their ſize and ſtrength: the largeſt and ſtrongeſt being placed in the centre rows; the ſmalleſt and weakeſt on the outſide. No Tulip root, however ſtrong, ſhould be planted more than four inches deep from the crown of it; nor ſhould any blooming root be ſet leſs than two inches and a half or three inches deep, however ſmall it may be. The ſoil which is made uſe of for covering the bulbs, ſhould have been frequently turned over, and well expoſed to the ſun and air, ſome time before it is uſed, that it may be perfectly ſweet, and free from that acrid quality which moſt ſoils are ſubject to, when taken conſiderably below the ſurface.

If the bed contain but five rows, with a path in front only, the ſmalleſt and loweſt-growing roots ſhould be planted in front, and ſo on to the laſt row, which ſhould contain the ſtrongeſt and largeſt: and the bed may ſlope towards the front; in which caſe the back ſhould be ſupported with boards or brick-work, to prevent the earth from crumbling down, and leaving the roots bare.

When the planting is finiſhed, hoop the bed over, that it may be covered occaſionally with mats or canvas, to preſerve it from heavy rains and ſevere froſts: either in moderation will be of more ſervice than injury to it.

By the end of february every plant in health will be above ground, except a few very late ones, which may be a week longer before they appear. If any canker is diſcernible, it ſhould be carefully cut out with a ſharp knife, on ſome fine dry day.

If the ſurface of the bed appears to be of too cloſe a contexture, it ſhould be carefully ſtirred up, about two inches deep.

By the end of april, ſome of the plants may be grown ſo tall as to require the hoops to be raiſed a little. As ſoon as any of the earlier ones begin to ſhow colour, they ſhould be ſhaded from the ſun, which will cauſe the colours to run and intermix in

ſuch

Digitized by Google

ſuch a manner as to deſtroy the elegance and beauty of the flower; ſome are more liable to this injury than others, and may be ſpoiled in five minutes.

When the greater part of the flowers have begun to open, a frame or awning ſhould be erected over the bed and paths, to keep out the rain, and to admit as much light as poſſible; for which purpoſe the cloth covering ſhould be rolled up in the morning early, if the weather be favourable, otherwiſe the colours of the flowers will be faint and weak. This cloth covering ſhould come down on each ſide within about three feet of the ground, to allow a free circulation of air, except in windy weather, and then the windward ſide muſt be protected quite to the ground.

Tulips never require to be watered; but moderate rains may be admitted before, and in ſmall quantity after the bloom is over; early in the ſpring they are neceſſary, in order to procure a ſtrong bloom.

When the awning is erected, the hoops ſhould be carefully taken away; the ſides and ends of the bed neatly boarded up, and the paths lowered two or three inches, to bring the flowers nearer to the eye: a ſlight frame about two feet high, ſhould ſurround the bed, to prevent any injury being done to the flowers: lines of ſmall twine, painted green, ſhould paſs from one end of the bed to the other between the rows of flowers; and to theſe the ſtems are to be looſely tied with ſhort pieces of green worſted. The awning may be continued on for three weeks with great ſafety.

When the petals of many flowers begin to drop off, the awning ſhould be taken down, together with the frame, boards, &c. and the mats and hoops replaced, to throw off exceſs of rain. As the petals fall, the ſeed-veſſel ſhould be broken off, cloſe to the ſtem; for if this be ſuffered to remain on the plant, it will weaken the root conſiderably.

The bed may remain in this ſtate about a fortnight longer, by which time the foliage will become of a yelloviſh brown, and two or three inches at the top of the ſtem will wither, dry up, and become purpliſh: this denotes the critical period to take up the roots: if it be done earlier, they will be weak and ſpongy; and if deferred later, their juices will become groſs; and at the next blooming the flowers will be what is generally termed foul.

When the roots are taken up, they are to be gradually dried, and kept dry. In auguſt or ſeptember take off the looſe ſkins, fibres, and ſuch offsets as are eaſily ſeparated; obſerving not to leave the roots too bare. The laſt brown ſkin, which is intimately connected with the root, ſhould remain on it till the time of planting; it ſhould then be entirely ſtripped off, and the root left perfectly bare and white; but it ſhould be performed with great care with a ſmall ſharp-pointed penknife, to avoid bruiſing or wounding the root, eſpecially at the lower end, where the fibres are formed, for that is at this time extremely tender, and will ſcarcely bear to be touched.

The ſmalleſt and weakeſt offsets, particularly ſuch as are not provided with a brown ſkin, may be replanted as ſoon as they are taken up, about an inch and half deep, in a freſh ſandy loam, in a dry ſituation, defending the bed from heavy rains by hoops covered with mats; or they may be buried in dry ſand till the autumn, and then planted with the larger roots, only not quite ſo deep.

Tulips are hardier than moſt other flowers; the offsets, and more ordinary ones may be planted in any part of the garden, from two to four inches deep, according to the ſize of the roots, in a good ſound ſoil, with a little rotten cow-dung, placed from ſeven to twelve inches below the ſurface.

Hail-ſtorms are very injurious to the foliage of Tulips, early in the ſpring: therefore although it is not neceſſary to cover the beds of inferior Tulips, during a common winter, yet it is highly proper to defend them againſt ſpring ſtorms, and to cover them when in bloom, in caſe of hot or windy weather[r].

DESCRIPTIONS, *&c.*

1. Stem ſhrubby, eight or ten feet high, ſending out branches on every ſide the whole length. Leaves ovate-lanceolate, two inches and a half long, and an inch and half broad, rough on their upper ſide, and of a lucid green, their under ſide has many ſtrong veins, and is of a lighter green, the edges are ſerrate: the flowers ſit cloſe upon the footſtalks of the leaves, having two pretty large leafy appendages to the calyx. The corolla is large and of a bright yellow. [Capſule ſuperior, ovate, indiſtinctly three-cornered, pubeſcent, opening from the top to the middle in three parts. Receptacle, three raiſed lines, inſcribed longitudinally on the inner wall of the capſule, accompanied by very numerous ſhort umbilical chords. Seeds ſlightly curved inwards, attenuated towards the navel, ſcored with many minute excavations in rows, cheſtnut-brown: aril halved, tongue-ſhaped, membranaceous, thin, whitiſh, lying on the concave part of the ſeed, free on all ſides, inſerted into the navel [z].]

Found by Father Plumier in Martinico; it is native of other parts of the Weſt Indies. [Browne ſays, it grows in great abundance about the red hills in Jamaica, and ſeldom riſes above four or five feet from the root; that it has a ſhrubby but weakly ſtalk, with a few ſerrated ovate leaves, and large yellow flowers, having ſomewhat of the appearance of the malvaceous tribe at firſt ſight.

Cultivated in 1733, by Mr. Miller [a].

β. Narrow-leaved Turnera has a ſmaller corolla, with pointed petals; the bractes have no glands; the leaves are more obtuſe; the anthers orange not yellow [b].]

It riſes with a ſhrubby ſtalk to the height of eight or ten feet; with branches leſs ſlender and ſtiff than in broad-leaved Turnera. Leaves narrow-lanceolate, hairy, near three inches long, and about three quarters of an inch broad, terminating in acute points, obtuſely ſerrate on their edges, and ſtanding upon very ſhort foot-ſtalks: when rubbed they emit a diſagreeable odour. The flowers are of a pale yellow; the petals large and oval, with the tails or claws twiſted and joining. They are not ſo large or of ſo bright a yellow as in the true Elm-leaved Turnera. Sloane firſt diſcovered it in Jamaica, [where he ſays it grows between Guanaboa and the town on the Red Hills very plentifully, and in ſeveral other places of the iſland.]—This as well as the other was obſerved by Dr. William Houſtoun in ſeveral parts of America, and was cultivated in 1733, by Mr. Miller, who conſidered it as a diſtinct ſpecies, having found from an experience

[z] Gærtner. [a] Hort. kew. [b] Linn. ſyſt.

of thirty years, that plants raiſed from its ſeeds, conſtantly differed from thoſe of the ulmifolia. [Mr. Curtis alſo has given it as a ſpecies; and informs us, that the narrow-leaved Turnera is generally known to the nurſerymen about London as the ulmifolia, to which name the foliage by no means anſwers. The true Elm-leaved Turnera is figured in Martyn's Decades, and in Linneus's Hortus Cliffortianus. On the ſame plate in the former of theſe works, there is a very excellent figure of what he conſidered as another ſpecies, and which is this narrow-leaved variety. It flowers from june to auguſt: the flowers are ſhowy, but of ſhort duration. The circumſtance of their growing out of the footſtalk of the leaf is remarkable [c].

I am at a loſs to underſtand what Linneus means by the leaves of this variety being more obtuſe than the other, for they are rather acuminate. The petals are very obtuſe at the top, and crenated there, with ſometimes a ſhort point, ſtanding out in the middle. See Mr. Curtis's figure.

2. Root annual, branching, thready. Stem herbaceous, from three to ſix inches high, branched, nearly upright, but often decumbent, round, hirſute; branches ſimple, erect. Leaves alternate, diſtant, broad-lanceolate, ſhort, deeply ſerrate, nerved, hirſute, cluſtered towards the end of the branchlets, ſpreading. Petioles round, ſhort, hirſute, terminating, flower-bearing. Stipules two, linear, erect, at the baſe of the leaves, within which is a ſmall yellow flower, ſcarcely open. Flowers terminating, cluſtered, in the centre of the leaves. Calyx corolliferous, connate with the corolla; ſegments linear, acute, preſſed to the corolla, erect, hirſute. Corolla deciduous: claws linear, long, roundiſh at top, veined, orange; border convoluted ſo that the corolla is ſcarcely open. Filaments of the ſame length with the petals, erect. Anthers oblong, blue. Germ ovate. Valves of the capſule ovate, acute, revolute. Seeds roundiſh, compreſſed, wrinkled, brown. Native of Jamaica, in dry ſandy fields; flowering towards the end of the year [d].

Brown named this plant and the ſeventh ſpecies Pumilea, from their ſmalneſs. This, he ſays, grows about Old-harbour, and the foot of Liguanea mountains; is always ſimple and upright, and never riſes more than two or three inches; the flowers always ſolitary, from the axils of the upper leaves.

3. This is a ſhrub three feet high. Leaves alternate, ſeſſile, narrow, oblong, toothletted, acute. Flowers ſmall, yellow, axillary, ſolitary. Native of Guiana. Aublet found it in the moiſt clefts of rocks, on the high banks of the river Sinemari; flowering and fruiting in november [e].

4. Stems palmary, ſimple, hairy. Leaves alternate, ſubſeſſile, deeply ſerrate except towards the baſe where they are quite entire, very evenly tomentoſe on both ſides, hairy beneath along the veins and edge. Flowers ſolitary in the axils, on very ſhort peduncles. Bractes on the peduncle two oppoſite linear rough-haired length of the calyx. Calyx turbinate, five-cleft, hairy. Petals obovate, inſerted into the calyx. Filaments ſhorter by half than the petals. It agrees with T. ciſtoides in having a hairy ſtem; but that wants the bractes and the nap on the leaves. Native of Braſil. *Arduini* [f].

5. This is a ſhrub eight feet in height. Leaves alternate, ſubſeſſile, lanceolate, acute, toothletted, yellowiſh green. Flowers axillary, yellow, ſmall, ſolitary. Native of Guiana, in clefts of rocks, on the banks of the Sinemari, flowering in december.

6. This is an annual plant, with a fibrous root. Stem branched, two feet high, hirſute with rufeſcent hairs. Leaves alternate, ovate, oblong, toothed, villoſe, wrinkled, ſubſeſſile. Flowers at the ends of the branches and ſtem, ſolitary, axillary, on long peduncles. The whole plant is covered with rigid rufeſcent hairs. Native of Cayenne and Guiana on ſandy coaſts [g]. Not only Aublet gave it as a genus diſtinct from

[c] Curt. magaz. [d] Swartz. [e] Aublet. [f] Linn. mant. [g] Aublet.

Digitized by Google

Turnera under the name of Piriqueta; but Schreber alſo under that of Burcardia.

7. Root annual, undivided, long, erect, white, thready. Stem ſubdivided, erect, half a foot high, round, hirſute; with alternate, ſpreading branches. Leaves on ſhort petioles, linear-lanceolate, bluntiſh, ſpreading, toothed or ſerrate, nerved, ſomewhat hiſpid. Bractes none. Flowers ſolitary in the axils, peduncled and not ſeſſile on the petioles, yellow, ſmall. Peduncles ſhorter than the leaves, round, filiform, hirſute. Calyx corolliferous: ſegments lanceolate, acute. Petals contiguous, rounded, entire, ſlightly ſtriated. Filaments ſhorter by half than the petals, from the baſe of the corolla: anthers oblong, vertical, yellow. Germ oblong, ſubtrigonal: ſtyles diverging: ſtigmas pencilled. Capſule roundiſh: valves ovate, revolute. Seeds minute, roundiſh, ferruginous[h]. Browne ſays, it ſeldom riſes above four inches; that it is erect, and has very narrow leaves; and that the flowers grow ſingle at the axils of the upper leaves.

Native of Jamaica, Surinam, &c. in South America.—Introduced in 1774, by Monſ. Richard. It flowers from june to october[i].

8. This is an annual plant, with an upright rough-haired ſtem, ſuberous at the baſe. Peduncles very long one-flowered[k]. Flowers yellow[l].

9. This plant puts forth from the root a ſomewhat woody ſtem, two feet high. Leaves alternate, linear, ſerrulate, ſeſſile, biglandular towards the baſe. Flowers in terminating ſpikes, on ſhort peduncles, each biglandular at its riſe. Corolla yellow. Capſule ſubtrigonal, three-valved. Seeds three, wrinkled. Native of Guiana in marſhy meadows; flowering in april[m]. Annual[n].]

PROPAGATION AND CULTURE.

Theſe plants are eaſily propagated by ſowing their ſeeds on a hot-bed early in the ſpring, and when the plants are come up two inches high, they ſhould be tranſplanted into ſmall pots, and plunged into a hot-bed of tanners bark, obſerving to water and ſhade them until they have taken root; after which they muſt be treated as hath been directed for the Guavas, and other tender plants from the ſame countries. The ſeeds of theſe plants will often fall into the pots which are placed near them in the ſtove, which will grow, and ſoon furniſh plants enough, after a perſon is once poſſeſſed of them. As they are too tender to live in the open air in England, they muſt be placed in the bark-bed in the ſtove, where, during the winter ſeaſon, they muſt be kept warm and frequently watered; but in the ſummer ſeaſon they muſt have a great ſhare of air, otherwiſe they will draw up tender, and not produce many flowers.

When the plants are grown pretty large, they may be treated more hardily, by placing them in the dry ſtove; where, if they are kept in a moderate degree of heat, they will thrive and flower very well. Thoſe who would ſave the ſeeds of theſe plants, muſt watch them carefully, becauſe, when they are ripe, they ſoon ſcatter if they are not gathered.

Theſe plants produce their flowers great part of the year, if they are kept in a proper degree of warmth, ſo that there are ſome of the flowers in beauty for at leaſt nine or ten months, which renders the plants more valuable.

They ſeldom continue more than two or three years.

SPECIES.

1. Turræa virens.
   Lin. ſyſt. 399. *Reich.* 2. 271. *Willd.* 2. 555. *mant.* 237. *Smith ic. ined.* 1. *t.* 10.
   Leaves elliptic-lanceolate emarginate very ſmooth, calyxes and fruits ſilky-villoſe.
2. Turræa pubeſcens.
   Lin. ſpec. ed. Willd. 2. 555. *Hellen. act. holm.* 1788. *p.* 296. *t.* 10. *f.* 3.
   Leaves ovate emarginate pubeſcent beneath, calyxes villoſe.
3. Turræa maculata.
   Lin. ſpec. ed. Willd. 2. 555. *Smith ic. ined.* 1. *t.* 11.
   T. glabra. *Cavan. diſſ.* 7. 360. *t.* 204.
   Leaves ovate acute ſmooth, calyxes ciliate.
4. Turræa ſericea.
   Lin. ſpec. ed. Willd. 2. 555. *Smith ic. ined.* 1. *t.* 12.
   T. tomentoſa. *Cavan. diſſ.* 7. 361. *t.* 205.
   Leaves ovate bluntiſh tomentoſe on both ſides, calyxes peduncles and petals villoſe.
5. Turræa lanceolata.
   Lin. ſpec. ed. Willd. 2. 556. *Cavan. diſſ.* 7. 361. *t.* 205. *f.* 1.
   Leaves lanceolate rounded on both ſides ſmooth, ſegments of the calyx very long lanceolate.

DESCRIPTIONS, &c.

1. This is an evergreen tree or ſhrub, with ſcattered divaricating leafy branches, and a ſmooth cloven bark, ſilky-villoſe on the twigs. Leaves alternate, ſubacuminate, quite entire, a little rolled back at the edge, naked ſhining and veined on both ſides, paler beneath. Petioles very ſhort, ſilky, curved inwards. Stipules none. Flowers lateral ſhaped into a very ſmall axillary ſpike, with a few ſmall leaves interpoſed. Bractes ſmall linear villoſe. Peduncles angular one-flowered ſomewhat ſilky. Calyx ſmall pentangular. Petals linear-lanceolate tender naked yellow. Nectary tubular oblique, widening a little towards the top, ſtriated, ſegments linear acute bent down ſpreading. Stamens placed alternately between the ſegments of the nectary. Anthers ſubovate, inargined, in the throat of the nectary. Style declined, deciduous. Capſule depreſſed, ten-valved, five-celled. Allied to Melia; Swietenia and Trichilia in the nectary, but very diſtinct from them all in the fruit. Found by Koenig among heaps of ſcoriæ on worn-out volcanos in the Eaſt Indies.

Hellenius, in the Stockholm acts for 1788, has deſcribed a ſpecies very different from this under the name of Turræa virens. Dr. Smith thinks this and another, which he names T. pubeſcens (*n.* 2.) are doubtful ſpecies; the anthers being on the tips of the nectary, not between the ſegments, and the fruit being unknown[o].

2. Leaves entire or emarginate membranaceous; flowers umbelled. Fruit as yet unknown. Native of the iſle of Hainam.

3. This is a tree with deciduous leaves, alternate branches, and a cloven but very ſmooth bark. Leaves alternate elliptic quite entire, ſmooth on both ſides, with pale ſpots beneath eſpecially near the nerves. Petioles ſtraight channelled ſmooth. Stipules none.

[h] Swartz. [i] Hort. kew. [k] Willdenow. [l] Jacquin. [m] Aublet. [n] Willdenow. [o] Smith ic. ined.

Digitized by Google

Flowers in lateral bundles, with small acute ciliate bractes interposed. Peduncles smooth, thicker towards the top, one-flowered, erect. Calyx small, hemispherical, smooth, ciliate at the edge. Petals very long, linear, yellow, a little wider at the end, pubescent on the outside. Nectary of the same length and colour with the petals, exactly cylindrical, very slender, smooth, ten-streaked, margin ten-cleft, the clefts linear-lanceolate acute spreading. Stamens in the throat of the nectary. Style of the same length with the nectary. Native of Madagascar, where it was found by Commerson. Communicated by Thouin.

4. This also is a tree with deciduous leaves. Branches alternate, with a dusky bark slightly pubescent. Leaves alternate elliptic quite entire, on both sides, the younger ones at least, very softly villose, nerved; the nerves straight. Petioles straight, villose. Stipules none. Flowers from the lateral buds, mostly solitary, very large red drooping, bursting forth whilst the leaves are yet tender. Bractes numerous acute villose. Peduncles short thick angular tomentose-hoary. Calyx bell-shaped angular, the whole tomentose-hoary not ciliate. Petals four inches in length linear recurved, ovate and obtuse at the end, hoary on the outside. Nectary the length of the petals, curved in, hairy, scarcely widening at the top, border ten-cleft; clefts bifid linear acute spreading. Stamens in the throat of the nectary, with the anthers standing out between the clefts. Anthers two-horned. Style a little longer than the nectary. Stigma club-shaped. Found in Madagascar by Commerson, and communicated by Thouin [p].

5. Stem frutescent, covered with a gray bark; branches wand-like. Leaves alternate, subcoriaceous, shining, quite entire, one-nerved, pale beneath, supported on short petioles. Stipules none. Peduncles axillary, one or two-flowered. Petals yellow with a scarlet base. Fruit covered with a rufous nap. Found by Commerson in Madagascar [q].

TURRÆA. See *Trichilia*.

TURRITA. See *Arabis*.]

TURRITIS. (*From* turris, *a tower. Linnæus says, because it is tall and narrow.*—Ray, *that it had the name*—ab extremorum caulium forma, qui in metæ aut pyramidis effigiem definit.)

Lin. gen. n. 819. *Reich. n.* 883. *Schreb. n.* 1095. *Tournef. Dill. gen. Juss.* 238. *Gærtn. t.* 143.

Class 15. 2. Tetradynamia Siliquosa.

Nat. order of *Siliquosæ*, *Cruciformes* or *Cruciferæ*.

GENERIC CHARACTER.

CAL. *Perianth* four-leaved: *leaflets* ovate-oblong, from parallel-converging, deciduous.

COR. four-petalled, cruciform. *Petals* ovate-oblong, obtuse, erect, entire: *claws* erect.

STAM. *Filaments* six, awl-shaped, erect, length of the tube: two of them shorter. *Anthers* simple.

PIST. *Germ* length of the flower, round, somewhat compressed. *Style* none. *Stigma* obtuse.

PER. *Silique* longest of all, stiff, four-cornered; angles opposite alternate obsolete and somewhat compressed, two-celled, two-valved: *valves* scarcely equal to the partition.

SEEDS very numerous, roundish, emarginate.

ESSENTIAL CHARACTER.

Silique very long, angular. *Cal.* converging, erect. *Cor.* erect.

SPECIES.

[5. Turritis patula.

Lin. spec. ed. Willd. 3. 544. *Ehrh. beitr.* 7. 259.

All the leaves hispid, stem-leaves embracing toothed at the end, branches spreading.

6. Turritis pubescens.

Lin. spec. ed. Willd. 3. 544. *Desfont. atlant.* 2. 92. *t.* 163.

All the leaves hispid, stem-leaves sessile bluntly toothed at the end, branches spreading.

7. Turritis ciliata.

Lin. spec. ed. Willd. 3. 544. *Schleicher cat.* 59.

Leaves smooth, stem-leaves sessile toothed at the base, with forked ciliate hairs at the base and tip.

8. Turritis alpina.

Lin. syst. 600. *Reich.* 3. 275. *Willd.* 3. 545. *Hoffm. germ.* 240. *Krock. silet. n.* 1093.

Root-leaves toothed hispid, stem-leaves half embracing.

DESCRIPTIONS, &c.

1. Root annual, (biennial, *Lin. and Curt.*) fusiform. The straight upright wand-like stem is two feet or more in height (one to three *Curt.* two to three *Woodw.* a foot and half *Miller.*) round, leafy, at first simple, but producing a few lateral upright flowering-branches after the main spike of pods is full grown; (near the ground hairy, but smooth above, *Curtis.*) Root-leaves lanceolate, broadly toothed and almost sinuate, rough on both sides with rigid forked or simple hairs: stem-leaves numerous, alternate, sessile, upright, sagittate, entire, smooth, glaucous, embracing. Flowers numerous, small, in a corymb which soon becomes a spike: petals pale sulphur-coloured (or greenish white, *With.*) entire. Pods long, linear, flat, bursting at their base, and containing a great number of seeds [r]. — Pods upright, approximating to the stem so as almost

[p] Idem. [q] Cavanilles. [r] Engl. bot.

to conceal it; roundish somewhat flattened, faintly quadrangular, *Curt.* When fully grown cylindrical, compressed, *With.* According to Gærtner, three inches and more in length, linear, rhomb-compressed, smooth: partition membranaceous, parallel to the valves, or equal to the greatest breadth of the pod, terminated by the stigma which is sessile and shortly two-necked; valves in the middle very obtusely angular. Seeds about sixty in each cell, ovate compressed a little, terminated by a very narrow almost obsolete membranaceous margin, fulvous, (reddish brown, *Curt.*)

Scarcely to be distinguished from Arabis either by its natural habit or technical characters[t]. Pollich remarks that he could not discover any nectareous glands; Scopoli however mentions them. Gærtner says, that the great length of the pod is the best mark of the genus.

Native of most parts of Europe in pastures, pits and other waste places, and on banks near hedges, on a dry gravelly soil; flowering from may to july. Near London not common; Mr. Curtis noticed it only near Charlton, but says that farther on in Kent it is more common, as well as in many other parts of England. It has been found near Lewisham. A. B. Lambert, Esq. and Mr. Groult gathered it near Richmond. It occurs in several parts of Norfolk, as between Norwich and Yarmouth in many places, at Spixwort, and in the road to Coltishall. The Rev. H. J. Wollaston found it in Thurston churchyard, Suffolk, and in the field adjoining. Near Colchester in Essex, by Hudson. Stow wood in Oxfordshire, by Sibthorp. Near Lichfield, by Mr. Whateley. Near Castle Bromwich, by Mr. Jones. Between Ashbourne and Okeover in Derbyshire, by Dr. Stokes. In the quarries above Bath, by Mr. Swaine. On St. Vincent's rocks near Bristol, by Dr. Withering. About Darfield near Barnesley in Yorkshire, by Mr. Salt[t].

Mr. Curtis remarks, that it varies so much in size, that the old botanists make two species of it. Dr. Withering would have it named Towerwort in English[u].

2. Root biennial. Stem quite simple, a foot high. Root-leaves smooth, obtuse, very slightly serrate, petioled: stem-leaves smooth, sagittate; the lower ones an inch long, lanceolate, obtuse, serrate at the top; the rest an inch and half long, narrow, lanceolate-linear, quite entire. Flowers like those of the preceding, but a little smaller. Pods erect. It is clearly distinct from the preceding, which it otherwise resembles, by its smooth obovate serrate root-leaves, and its narrower lanceolate-linear stem leaves. Native of Pensylvania.

3. Stem quite simple, two feet high, erect. Root-leaves scarcely toothed: stem-leaves shining, narrowed at the base, remotely and sharply toothed. It is allied to the next succeeding species, from which it differs chiefly in its smoothness. Native of Piedmont, in moist meadows[x].

4. Root strong, woody, perennial. Stems generally several, one of which is much stronger than the rest, erect, a foot high, leafy, branched round, clothed with thickset, simple, white, prominent hairs; the upper part and flowering branches smooth. Leaves toothed, all more or less hairy with simple or forked hairs: root-leaves slender at the base: those on the stem sessile or partly embracing. Flowers small, white. Pods numerous, forming a very long spike, erect, but finally nodding, narrow-linear, compressed, but with four angles, smooth and somewhat shining, beaded as it were by the projecting seeds, rather blunt at the top, and crowned with the almost sessile stigma[x].

Mr. Woodward remarks, that the plant does not grow so tall, and that the pods are not nearly so numerous as in the smooth Towerwort. The corolla also is white; and Mr. Miller observes that it flowers earlier. Scopoli has ranged it in the genus Arabis on account of its glands.

Native of many parts of Europe, on rocks, in stony places, on old walls and castles, and in dry mountainous pastures; flowering in may. In the western and northern counties, by Ray. Near Midhurst in Sussex, by Doody. In Switham bottom near Croydon in Surry, by Hudson. On Lakenham church near Norwich, by Mr. Crowe. Near Bury in Suffolk, by W. Matthew, Esq. In several places in Cambridgeshire. Rewley Abbey, Oxfordshire, by Dr. Sibthorp. Ruins of Old Sarum. St. Vincent's rocks. Wick Cliffs. Baydales, Darlington. About Settle. King's park, Edinburgh, &c.

Linneus originally confounded with this, not only T. alpina, which has all the leaves smooth; but also T. hirsuta of Gerard's Flora Galloprovincialis, which has perfectly flat pods without any lateral angles, and the hairs on its stem depressed and forked, as are all those on its leaves; which in the proper T. hirsuta are for the most part simple[y].

5. Root annual. It is different from the hirsuta in this circumstance, in being of a smaller stature, in having a more flexuose stem, with spreading instead of upright stiff branches; the leaves toothed towards the tip, not as in the hirsuta in the middle and towards the base. It agrees with that species, which it resembles very much, in its hairiness, forked hairs, leaves cordate at the base, and smooth calyx. Native of Hungary, on open hills.

6. This also resembles T. hirsuta, but the branches are spreading, the leaves obtusely toothed towards the tip, the stem-leaves sessile attenuated at the base not cordate[z]. Desfontaines says that it is less villose, that the stem-leaves are more deeply toothed; and the pods fewer and pubescent. Native of Algiers on the mountains.

7. The whole of this is smooth, the stem quite simple and erect, the root-leaves oblong, attenuated at the base into the petiole, ciliate along the margin and at the base and tip with forked hairs, stem-leaves attenuated at the base and toothed, ciliate at both ends with long forked hairs. Native of Switzerland[a].

8. Stature the same as that of T. hirsuta, but the stem even, and the stem leaves altogether smooth, quite entire, sessile or little cordate at the base and blunt, scarcely half embracing. The flowers are larger: the petals white, very blunt, obovate-oblong, twice as long as the calyx; which is compressed a little and erect. The flowers indicate that this is different from the hirsuta[b]. Native of Germany, Silesia, Austria.]

PROPAGATION AND CULTURE.

If the seeds be permitted to scatter, or if they be sown on a wall, among rock-work, or in a dry border, there is no hazard of these plants maintaining their situation.

TURRITIS. See *Arabis*, *Brassica*, *Cardamine*, *Dentaria*, *Erysimum*, *Hesperis*, *Sisymbrium*.

Class. 19. 2. Syngenesia Polygamia Superflua.

Nat. order of *Compositæ Discoideæ*. *Corymbiferæ* Juss.

GENERIC CHARACTER.

CAL. *Common* cylindrical: *scales* lanceolate-linear, (15 or 20,) equal, as long as the disk, submembranaceous.

COR. *Compound*, various.

Corollets in some all hermaphrodite and tubular, or only in the disk.

Females in some none, in others ligulate.

Proper of the Hermaphrodite funnel-form: *border* five-cleft (or four-cleft,) acute, reflexed, longer than the calyx.

Females none, or ligulate, very narrow, longer than the calyx, entire.

STAM. in the Hermaphrodites; *Filaments* five, capillary, very short. *Anther* cylindric, tubular.

PIST. in the Hermaphrodites. *Germ.* short. *Style* filiform, longer than the stamen. *Stigma* thickish.

[t] Idem. [u] Smith brit. With. &c. [x] Willdenow. [y] Idem. [z] Willdenow. [a] Idem. [b] Linn. syst. Smith brit. and engl. bot.

PER.

In the Females *Germ* ſhort. *Style* filiform, length of the hermaphrodite. *Stigma* bifid, thickiſh.

PER. none. *Calyx* ſcarcely changed.

SEEDS in the Hermaphrodites ſolitary, oblong, compreſſed. *Down* capillary, ſtipulate.

In the *Females*, if any, like the others.

REC. naked.

OBS. Petaſites Tourn. *has no ligulate florets in the ray, though in ſome there are naked female florets.*

Tuſſilago Tourn. *has always female florets in the ray, with a ligulate corolla.*

Anandria *has a ſeſſile down.*

T. frigida *varies with floſcular and radiate flowers.*

ESSENTIAL CHARACTER.

Cal. ſcales equal, as long as the diſk, ſomewhat membranaceous. *Down* ſimple. *Recept.* naked.

Thyrſe ovate, almoſt all the florets hermaphrodite ſyngeneſious.]

DESCRIPTIONS, *&c.*

1. This is a very low plant, the leaves of which grow cloſe to the ground. The flowers ſtand upon ſhort foot-ſtalks which riſe between the leaves, and are three or four inches long, each ſuſtaining one flower at the top, of a dirty purpliſh colour. Theſe appear early in the ſpring, and are ſucceeded by downy ſeeds which ripen in june.

[Stem none. Root perennial, with branching radicles, creeping far and wide. Leaves radical, ſubovate, ſublyrate, veined, on long erect petioles. Scape one-flowered, thick, ſhorter than the leaves, with acute imbricate ſcales. Flower yellow, with an erect ſomewhat open calyx [c].

In cooler ſituations the calyx is cloſed and the flower floſcular; in warmer ones the flower is radiate and ſpreading. The down is ſeſſile and hairy [d]. Native of Siberia, and the northern provinces of China.

2. Native of America.

3. Root annual, ſimple. Leaves radical, a finger's length, webbed above, white-tomentoſe beneath. Scape longer than the leaves, more tomentoſe at top. Calyx oblong, imbricate; ſcales ſomewhat pappoſe, linear, acute. Seeds ſtriated. Down rufeſcent. Native of Jamaica [e].

4. Annual. Native of Jamaica [f].

5. This is an annual ſtemleſs plant, about a foot high. Leaves radical, petioled, wedge-ſhaped, ſometimes ovate and only deeply toothed, gaſhed in the middle, gradually attenuated to the baſe, white tomentoſe beneath. Scape long, ſimple, ſomewhat tomentoſe. Flower nodding during the time of flowering, ſolitary. Calyx imbricate: ſcales lanceolate-ovate, tomentoſe at the baſe. Corolla radiate: corollets of the diſk five-cleft, white; of the ray ligulate, longer than the calyx, linear, bifid, purple. Seeds angular. Native of Jamaica [g].]

6. This is a low perennial plant. The upper ſurface of the leaves is ſmooth and of a bright green colour; the under a little downy and whitiſh: their foot-ſtalks ariſe from the ground, and are three inches long. The peduncles ſpring from the root, are four inches long, woody, and ſuſtain one purpliſh flower at the top.

[Flower floſcular, with female florets in the ray. The ſcapes has one or two bractes [h].

The creeping root often produces two bundles of leaves, which are round, hard, and kidney-ſhaped, often toothed, and cottony underneath. From the centre of one of theſe bundles riſes a ſcape ſix or eight inches long, having one or two linear leaves on it, and a reddiſh flower at the top. Calyx hard and ſingle, a little ſwoln at the baſe where one or two ſcales are often found. It incloſes from forty to fifty florets, ten or fifteen of which are females naked at the edge; the reſt are floſcular. The ſeeds are grooved [i].

Scopoli and Jacquin make two ſpecies of this.

Native of the Alps; Switzerland, Auſtria, the South of France, Piedmont; alſo of Siberia.—Cultivated by Mr. Miller in 1731 [k]. It flowers in march, april and may.

[c] Loureiro. [d] Linn. ſpec. [e] Linn. ſuppl. [f] Swartz prodr. [g] Swartz obſ. [h] Linn. ſpec. & ſyſt. [i] Villars. [k] Hort. kew.

7. Root perennial, creeping horizontally far and wide. Scape erect, ſimple, from three to five inches high, lengthening after flowering, channelled, downy, clothed with lanceolate imbricate ſcales, preſſed cloſe to the ſcape, tinged with reddiſh brown. Flowers ſolitary, terminating, yellow, more conſpicuous on account of their radiate form than moſt of the other ſpecies. The calyx conſiſts of ſeveral ſimple parallel linear equal flat three-nerved ſmooth reddiſh brown ſcales, the length of the diſk, finally bent back, accompanied at the baſe by a few ſcattered ſcales like thoſe on the ſcape. Florets of the ray numerous, ſpreading, linear, in two or three rows, twice as long as thoſe of the diſk, with a more ſlender ſtigma. Seeds ſmooth, ſlightly attenuated upwards, roundiſh or indiſtinctly angular, pale brown or bay-coloured. Down ſeſſile, longer than the calyx, twice as long as the ſeed, ſcarcely toothletted, never ſtriped as Linneus makes it. Receptacle at firſt flat or ſlightly concave; afterwards pillowed and almoſt globular, pitted, naked and ſmooth. The leaves grow on long foot-ſtalks, cluſtered, from ſhort lateral branches; they are very ſmooth above, green with reddiſh veins, but tomentoſe-white beneath: when young they are rolled back, and in that ſtate they are thickly clothed with cotton, as is the ſcape alſo [l].

The flowers come up early in the ſpring before the leaves, and at ſome diſtance from them: they are upright, but as ſoon as the bloom is paſt, and the ſeeds with their down as yet moiſt are incloſed within the calyx, the heads hang down, as the moiſture evaporates in ripening they become lighter, are again erected, and the down expands [m]. The ſeeds, eſpecially in the diſk, are commonly barren. This is often the caſe with plants, which, like the Colt's-foot, run much at the root.

Native of Europe, Siberia and the northern provinces of China, in moiſt ſtiff clayey and marley ſoil; Dr. Withering remarks, that it is the firſt plant which vegetates in marle or limeſtone rubble.

The cotton on the leaves eaſily rubs off; this wrapped in a rag, dipped in a ſolution of ſaltpetre, and dried in the ſun, makes the beſt tinder. The leaves are the baſis of the Britiſh herb-tobacco. They are ſomewhat auſtere, bitteriſh and mucilaginous; were formerly much uſed in coughs and conſumptive complaints. Dr. Cullen has found them to do conſiderable ſervice in ſcrophulous caſes. He gave a decoction of the dried leaves, and found it ſucceed where ſea-water had failed. And Fuller relates the caſe of a girl, with twelve ſcrophulous ſores, who was cured by drinking daily as much as ſhe could for above four months, of a decoction of the leaves made ſo ſtrong as to be ſweetiſh and glutinous [n].

It is remarkable that the ſmoaking of Colt's-foot for a cough has the recommendation of Dioſcorides, Galen, Pliny, Boyle, &c. And Linneus ſays it is ſtill uſed in Sweden for this purpoſe. According to Pliny's direction it may be an efficacious remedy in a cough —" in ſingulos hauſtus, paſſum guſtandum eſt." A ſip of raiſin wine, or rather ſyrup, is to be taken after each puff [o]. Upon which Mr. Curtis obſerves, that this is the only account among the ancients which tends towards the practice of ſmoaking. He has given an excellent figure of this plant in his Flora Londinenſis, accompanied with a very entertaining account of its virtues, and the hiſtory of ſmoaking.

Colt's-foot derives the Greek Βηχιον, as well as the Latin name, from its property of curing coughs. The modern European names are taken from the ſhape of the leaves.

8. Leaves radical, cordate-orbicular, angular, toothed, naked above, obſcurely villoſe beneath, dichotomouſly nerved, a hand long. Petioles angular, ſubtomentoſe, a ſpan in length. Scapes ſtriate-angular, tomentoſe, erect, half a foot high. Bractes on the ſcape ſcattered, and under the petioles, ſolitary, lanceolate, above naked, beneath tomentoſe. Flowers alternate. Peduncles tomentoſe, one-flowered, ſeldom

[l] Smith brit. & engl. bot. Curt. lond. Woodw. mss. [m] Curtis. [n] Withering. [o] Curtis.

Digitized by Google

two-flowered; the lower ones longer, a finger's length; the upper ſhorter, aggregate, faſtigiate, an inch long. Scales of the calyx linear, ſubtomentoſe. Corollets yellow. Seeds of all oblong, roundiſh, villoſe. Down ſubfaſtigiate, white, the ſame length with the tube of the corolla. Root bitter, eſteemed a counterpoiſon by the Japoneſe [p].

Linneus, in mantiſſa, remarks that the leaves are the ſize of thoſe of Caltha; the ſcape a foot high; the flowers of the ſame ſize as in Arnica. Native of Japan.

9. Root perennial, creeping. Leaves all radical, triangular, excavated at the baſe into a deep ſinus, having ſeven or eight prominencies on each ſide, ſmooth above, white-tomentoſe beneath. Petioles ſlender, ſcarcely a ſpan long. Scape a ſpan high, round, having one or two broad membranaceous embracing wings, ending in the rudiment of a leaf. Flowers from ſix to twelve, terminating, faſtigiate. Calyx oblong. Corolla white, rayed. Stamens in the florets of the diſk, but none in thoſe of the ray. Stigma bifid in the former, ſimple in the latter. Down thrice or four times as long as the calyx [q].

It varies, according to Linneus, in ſyſt. veg. with floſcular and with radiate flowers.

Monſ. Villars ſeems to have taken ſome pains to aſcertain this ſpecies. He deſcribes it as having in Dauphiné, a root creeping a little and aromatic, ſuperficial and much leſs deep or thick than in the alba, Petaſites, &c. Its heart-ſhaped leaves a little triangular, are on cylindrical woolly petioles, a foot long; they are unequally toothed like the common Colt's-foot, greeniſh and woolly above when young, but ſmooth and deep green in a more advanced ſtate, beneath ſnow-white. The flowers come out very early; they are frequently accompanied by a leaf or two, even at the baſe of the ſtem, which is eight or ten inches high, with reddiſh pointed ſcales on it, and terminated by eight, ten or twelve to fifteen flowers in a corymb: theſe have a reddiſh calyx compoſed of thirteen flat pointed ſcales, beſides three four or five ſmaller ones on the peduncle: the florets are all hermaphrodites white or ſlightly tinged with red, and forty-five or fifty in number. Seed brown, ſurmounted by a ſimple duſky egret.

He remarks that Moriſon's figure agrees well with the plant found in Dauphiné; that Linneus, Gmelin, Haller, Scheuchzer, Tournefort and Vaillant have all quoted this figure; that Linneus and Gmelin having found angular leaves and radiate flowers, he has deſcribed their plant exactly, and aſſembled a certain number of ſynonyms; and that Linneus having cited Haller, and the Swiſs plant not differing from that of Dauphiné, he has little doubt of its being the ſame with that of the north.

Native of Lapland, Switzerland, Sileſia, Dauphiné and Siberia.

10. Native of Newfoundland and Labrador. Perennial; flowering in april. Introduced in 1777, by John Fothergill, M. D. [r]. It is ſufficiently diſtinguiſhed by its palmate leaves.

11. Root perennial, leſs ſuperficial than that of the frigida, ſmaller and not ſtriking ſo deep as the Petaſites. Leaves of a ſize between them, kidney-ſhaped, villoſe on both ſides, ſoft, leſs firm, and of a yellowiſh green. Flowers of a beautiful white, on a ſcape from four to eighteen or twenty inches in height, diſpoſed in a corymb, from thirty to forty in number, on peduncles a little villoſe, having two or three ſcales, the lower ones two or even three-flowered, the others ſimple. Scape ſtriated, hollow: ſcales obtuſe, marked with ſeveral nerves. Calyx cylindric, compoſed of eighteen or twenty linear ſcales. Florets twenty to twenty-five, of which two or three at the edge are female. The piſtil of the females is ſimple and white; that of the hermaphrodites thicker and terminated by two lanceolate very apparent ſtigmas. It flowers earlier than the frigida [s].

Native of ſeveral parts of Europe. Cultivated in 1683, by Mr. James Sutherland [t].

12. Root perennial, thick and fleſhy, creeping very far. Leaves radical, heart-ſhaped, pointed, irregularly toothed, cut away cloſe to the ſide nerves at the baſe, very broad, downy beneath, ſtanding on long upright fleſhy cottony foot-ſtalks. Scape erect, riſing above the leaves, a foot and half high, ſimple, round, cottony, inveſted with lanceolate ſcales, the lowermoſt of which moſtly terminate in a ſmall leafy appendage. Thyrſe terminating, nearly ovate and denſe, after flowering cylindrical and more looſe: pedicels one or two-flowered, ſometimes three-flowered, ſlender, ſcaly and downy. Flowers fleſh-coloured, without any ray: calyx ſhort, nearly ſmooth, tipped with purple: florets very numerous, all tubular, and for the moſt part female, except two or three in the middle which are hermaphrodites, red, with the anthers either quite diſtinct or connected very ſlightly, and the ſtigma obtuſe, club-ſhaped, emarginate, and the germ always abortive; the females have a more ſlender and whitiſh corolla, a two-parted acute ſtigma, and a germ naturally fertile, but frequently abortive, as in other plants that run much at the root. Seed obovate. Down rugged, ſilvery-white. Receptacle pitted. Linneus deſcribes the female florets as naked, or without corolla, but in his own ſpecimen there is no floret naked. —We are almoſt perſuaded, ſays Dr. Smith, of what nobody has hitherto hinted, that this plant is the true female of T. Petaſites, being furniſhed with a ſmall proviſion only of the other ſex to perform its office occaſionally, as in Spinachia, Cannabis, Muſa, &c.

Native of Germany, Holland, Sileſia, Switzerland, Dauphiné, Piedmont, Britain; by the ſides of ditches: in ſeveral parts of Leiceſterſhire, about Mancheſter, near Banbury in Oxfordſhire. It flowers in april. The down of the ſeeds, forming a ſilvery plume, is very ornamental and conſpicuous [u].

13. Root ſcarcely creeping. Leaves radical, on long petioles, white-tomentoſe beneath. Scape near the root ſcaly-leafed, naked below white-tomentoſe above, the whole covered with lanceolate looſe tomentoſe ſcales. Flowers nearly upright, about twenty in a thyrſe. Pedicels a little longer than the flowers, having from two to four ſmooth linear bractes on them. Calyx compoſed of from twelve to ſixteen lanceolate obtuſe erect ſcales or leaflets, red at the tip. Female florets above eighty, length of the down, with the border ſcarcely widening, unequally trifid, the ſtyle long and exceeding the calyx, the ſtigma ſlightly bifid. In ſome the border being oblique appears to be entire, but then two minute toothlets may be obſerved at the baſe or the lower ſinus. Hermaphrodite florets about three, funnel-form, length of the calyx, with a five-parted erect border; the ſegments acute: anthers linear, ſtyle ſhort, ſtigmas two long, ſtraight, linear-lanceolate, ſhorter than the corollet. Down the length of the tube [x].

Native of Switzerland. Cultivated in 1758, by Mr. Miller. It flowers in april [y].

It is worth conſideration, ſays Dr. Smith, whether the T. alba may not ſtand in the ſame relation to this paradoxa, as Petaſites does to hybrida; the anthers in paradoxa being ſeparate as in hybrida, and united in alba as in Petaſites [z].

14. Root perennial, creeping very far, and increaſing rapidly ſo as to be extirpated with difficulty; in which reſpect it agrees with the hybrida, as well as in the appearance and form of its leaves, which however are ſomewhat larger in this. The ſcape is rather ſhorter, and the thyrſe is not ſo much lengthened out after flowering. The flowers are larger, and the ſcales of the calyx twice as long. All the florets are hermaphrodite in appearance, with the anthers united, and the ſtigma thickened and emarginate, but the germ entirely abortive. The younger Linneus and Haller have occaſionally noted a very few female florets to accompany the others, which the latter tells us produce good ſeeds. This circumſtance is rare, and has not been obſerved in England; nor, if general, would it invalidate the conjecture, that this is the real male of

[p] Thunb. jap. [q] Linn. lap. [r] Hort. kew. [s] Villars. [t] Hort. kew. [u] Smith brit. & engl. bot. [x] Retzius. [y] Hort. kew. [z] Engl. bot.

T. hybrida,

Digitized by Google

T. hybrida, forming but one ſpecies with that. All theſe plants increaſe ſo much by root, that impregnation rarely takes place, which is alſo the caſe with mints and many other vegetables. As the florets of the circumference only in this genus produce perfect ſeeds, the central ones having the thickened ſtigma which appears always to be barren, Dr. Stokes and Profeſſor Sibthorp would remove it to the order Polygamia Neceſſaria; but ſyngeneſious plants are ſubject to ſuch variations in the perfection of their organs of impregnation, that it is by no means certain how far that order, or indeed ſome others, are founded in nature[a].

Native of Europe. Common in Britain, on the banks of rivers and ditches: flowering in april. The roots abound with a reſinous matter: they have a ſtrong ſmell, and a bitteriſh acrid taſte. Linneus remarks, that the large leaves afford ſhelter from rain to poultry and other ſmall animals[b].

From the largeneſs of the leaves it had its Greek name Petaſites. In Engliſh, Butter-bur, from their being uſed formerly to wrap up butter in. Peſtilent-wort, from their ſuppoſed efficacy in the plague.]

PROPAGATION AND CULTURE.

Theſe plants are eaſily propagated by parting their roots in autumn, and muſt be planted in a moiſt ſhady border, where they will thrive, and require no farther care but to keep them clean from weeds.

[Colt's-foot is a bad weed on ſome lands, eſpecially ſuch as have been over-cropped and exhauſted. Ploughing and harrowing alone will not deſtroy it; but it muſt be drawn out by the roots, which may be eaſily done at no great expenſe where land is well tilled. Root weeds are hardly to be deſtroyed effectually any other way.

T. paluſtris minima, duplici clava. *Mor. hiſt. ſ.* 8. *t.* 13. *f.* 3.

Leaves ſemicylindrical-flattiſh, equalling the culm, male and female ſpike remote.

DESCRIPTIONS, &c.

1. Root perennial, creeping, the thickneſs of the human thumb, jointed, ſpongy, furniſhed with ſmall fibres of a whitiſh colour; the young ſhoots white, tender, terminating in a ſharp hard point, like quich-graſs. Stalk from three to ſix feet high, ſimple, upright, leafy, round and ſmooth, without knots, leafy at the baſe. Leaves alternate, upright, twiſted, at bottom ſword-ſhaped and fleſhy, at top flat, and of a blueiſh colour, about an inch in breadth, and two or three feet in length, incloſing the ſtalk in a very long ſheath. Sheaths two, deciduous, one at the bottom of the male ſpike, the other at the middle: Mr. Woodward remarks, that there is frequently a third ſmaller between the middle and the top of the ſpike. Filaments before the ſhedding of the pollen very ſhort, ſuſtaining from one to four anthers; the pollen being ſhed, they hang down and become longer than the anthers, which are four-grooved, and terminated by a greeniſh gland. The female ament is contiguous to the male; the germ very minute, ſitting on a ſhort foot-ſtalk; the ſtyle thickened above; and the ſtigma black. Seed very ſmall, on a downy peduncle, terminated by an awn. Receptacle of the male catkin hairy. The quantity of impregnating duſt in the male ſpike is exceedingly great, but proportioned to the great number of ſeeds in the female ſpike below; whether theſe generally vegetate has not yet been aſcertained: we only know that many plants which increaſe much by the root ſeldom produce perfect ſeed.

The part which Linneus deſcribes as the calyx, appears rather to conſiſt of ſome hairs proceeding from the receptacle, and which ſeem more evidently to be ſo, from the hairy appearance of the receptacle when the ſtamens drop off. Mr. Curtis thinks it would be much leſs puzzling, and perhaps more agreeable to the ſyſtem, to place this plant in the order Polyandria; there being many ſtamens, and all united to one receptacle.

Haller ſays that the roots are eaten in ſalads, that cattle eat the leaves, and that the downy ſeeds ſerve for ſtuffing pillows. Linneus relates, that coopers uſe the leaves to faſten the hoops round their caſks. Schreber affirms that the leaves are ſuſpected to be

V A C

poiſonous. Browne informs us, that in Jamaica, the leaves make good mats, and are ſometimes uſed for thatch.

The appearance of the Typha has engaged gentlemen fond of plants to introduce it on the edges of ponds; and painters frequently repreſent it in aquatic ſcenes[c]. Rubens has put it into the hand of Chriſt as a ſceptre when he was ſaluted as a king in mockery by Herod's ſoldiers.

This plant is a native of the four continents, is common in Britain, and has been found in Jamaica and in New Zealand: in ponds, ditches, and by the ſides of rivers and brooks. It flowers with us in july.

2. The ſmaller Cat's-tail differs from the preceding in having much narrower leaves, not exceeding one third the breadth of the other, ſemicyndrical below, flat and ſtrap-ſhaped towards the end, more ſlender ſpikes, though the plant grows as tall and as firm as the great Cat's-tail, and the male and female ſpikes about an inch aſunder[d].

Native of Europe, Barbary and Siberia. Gerarde ſays, that he found it in the Iſle of Shepey. Ray ſays, that he obſerved both ſpecies growing together in a brook near Leez houſe in Eſſex. He adds that it is no leſs common than the great one; that the leaves are not only narrower but of a paler green; the ſpike not only more ſlender, but leſs coloured and appearing earlier. Mr. Curtis remarked it on the middle of Woolwich common: Mr. Woodward in clay-pits in Norfolk and Suffolk: Mr. Relhan by the brick-kilns on the Cheſterton road, by the Cam below Ditton, in Swan pond, &c. Dr. Sibthorp, at Cowley: Dr. Abbot, at Knotting green in Bedfordſhire. Hounſlow heath.

β. Dr. Smith conſiders this as a diſtinct ſpecies, and thus deſcribes it. Culm a foot and half high, three times as ſlender as in T. anguſtifolia. Leaves flat, broadiſh, ſcarcely the length of half the culm. Spike three times as thick as in anguſtifolia, abbreviated, foliolоſe, interrupted, the upper ament either entirely male, as in the others, or female at bottom. Dr. Smith has admitted it in his Flora on the authority of Dillenius. He had it from the territory of Geneva.

He names it Typha minor, and thus characterizes it.—Leaves enſiform twice as ſhort as the culm, ſpike interrupted abbreviated incraſſated, culm extremely ſlender.

When growing among rocks, with its roots confined, it becomes ſmaller, with the ſpikes more numerous[e]. Ray ſays that he found this at the confluence of the Rhone and Arve near Geneva, where Lobel and John Bauhin had obſerved it before him[f]. It is ſaid alſo to have been found by Mr. Dandridge on Hounſlow heath[g].

PROPAGATION AND CULTURE.

Theſe plants increaſe ſo much by their creeping roots, that they ſoon choak up a ſmall piece of water, and overpower moſt other aquatics: they are beſt therefore cultivated for curioſity in a moiſt border of the garden, where they will flouriſh and produce ſpikes even more abundantly than in the water.

V A C

Leaves quite entire oval-oblong, obtuſe flat, ſtems creeping filiform.

DESCRIPTIONS, *&c.*

1. Root perennial woody. Stem ſhrubby, ereſt, ſcarcely a foot high, very much branched, forming a ſmall tufted buſh. Branches ſmooth, green, twiſted, ſharply angular eſpecially the young ones. Leaves alternate, on ſhort foot-ſtalks, ſmooth, veiny, bright green, without any ſtipules. Flowers axillary, ſolitary, on ſhort round ſimple peduncles, drooping, globular (or nearly ſo, but a little flatted at the baſe,) fleſh-coloured (or pale reddiſh purple,) inodorous. The calyx and corolla have each five teeth, the former very ſmall, and the teeth of the latter ſmall, reflected, reddiſh white. Stamens incloſed, very often or perhaps generally ten; the numbers four or five in the two former, and eight or ten in the latter, being indifferent in this natural order as to the determination of genera or ſpecies. Anthers cloven, diſcharging their pollen by a pore at each point, and accompanied beſides by two briſtles or horns, as in many of the Heaths. Germ obconical, green, ſmooth. Berry globular with a dimple at the top, five-celled before it ripens, but when arrived at maturity the numerous ſeeds are imbedded in one continued ſoft acrid blood-red pulp [b]: they are often deſcribed as black, but they are in reality very dark blue. There are as many as thirty ſeeds in a cell; they are oblong, angular, very finely ſtriated in waves, yelloviſh or of a red-ruſt colour [i].

Native of Europe, Siberia and Barbary, on heaths and ſtony moors, and in woods where the ſoil is ſpongy. It is abundant in the mountainous parts of Great Britain. On Porland heath, the higheſt ſpot in Norfolk. In Aſpley wood, Bedfordſhire; Dr. Abbot. Checkendon-woods near Clump Houſe; Dr. Sibthorp. Rocks above Great Malvern, Worceſterſhire; Mr. Ballard. The Biſhop's woods, near Eccleſhall. Lightwoods, near Birmingham; Dr. Withering. In the woods of Purbeck, Dorſetſhire, particularly at the Grange, the ſeat of John Bond, Eſq; Dr. Pulteney. Both Gerarde and his editor Johnſon mention its growing on Hampſtead heath. Near Loughborough in Leiceſterſhire. In Scotland abundant, both in woods and heaths.

About may the young freſh-green leaves, and wax-like red flowers, make an elegant appearance. Towards autumn the leaves grow darker and more firm, and the ripe berries are gathered in the north for tarts, and in Devonſhire are eaten with clotted cream [k].

The berries are very acceptable to children, either eaten by themſelves or with milk, or in tarts. The moor-game live upon them in the autumn. The juice ſtains paper or linen purple. Goats browſe upon the plant; ſheep are not fond of it; horſes and cows refuſe it [l].

The berries have an aſtringent quality; and in Arran and the Weſtern iſles are given in diarrhœas and dyſenteries with good effect. The Highlanders eat them with milk, and make them into tarts and jellies, which laſt they mix with Whiſkey to give it a reliſh to ſtrangers.

A variety with white berries was diſcovered by the Duke of Athol in the woods about midway between his two ſeats of Dunkeld and Blair [m].

2. Native of North America, where it was found by Samuel Martin, M. D. Introduced in 1772. It flowers in may and june [n].

3. Stem ſhrubby, very much branched. Branches alternate, round, divaricate and ſpreading very much, ferruginous, ſmooth: branchlets filiform, wrinkled, villoſe at the end. Leaves alternate, ſubſeſſile, acute, villoſe, a little paler beneath, ſpreading, unequal, half an inch long. Flowers ſcattered over the branchlets, ſolitary, drooping, on peduncles half a line in length. Calyx four-cleft, three times ſhorter than the corolla. Corolla five-cleft. Filaments eight, very ſhort. Anthers ovate, ſhorter than the corolla, pointed with an awl-ſhaped bifid tip. Style filiform, angular, a little longer than the corolla. Native of Japan, in the mountains between Miaco and Jedo [o].

4. Peduncles axillary, filiform, longer than the corolla. Corollas five-cleft, ſpreading bell-ſhaped. Anthers ten. Style longer than the flower [p].

Native of North America. Introduced in 1772 by Mr. William Young. It flowers in may and june [q].

5. This grows taller than the common Bilberry, (n. 1.) and the ſtem and branches are round. Leaves obtuſe, (ſometimes ſlightly dented at the end,) rarely inclined to be pointed, a little revolute, ſmooth and even, not at all rugged, glaucous beneath, with a network of veins, often tinged with red. Flowers fleſh-coloured or pink, the calyx and corolla moſtly four-cleft. Stamens generally eight, each with two horns as in V. Myrtillus. Berry large, globular, black with a glaucous hue. Seeds finely ſtriated [r].—The young leaves are ciliate at the baſe [s].

Native of many parts of Europe and of Siberia.—On marſhy mountainous heaths in Britain, but not general. Obſerved at Gambleſby in Cumberland, and in Whinfield foreſt, Weſtmoreland; by Ray: in the Highlands of Scotland, by Lightfoot. It flowers in april and may, and the berries ripen in auguſt. The fruit has leſs flavour than the common Bilberry, but abounds with a weak acid juice [t]. In large quantities it occaſions giddineſs, and a ſlight head-ach, eſpecially when full grown and quite ripe [u]. Many vintners in France are ſaid to make uſe of the juice to colour their wines red [x]. They furniſh an ardent ſpirit which is highly volatile and intoxicating. The alpine birds feed upon the fruit, and it is very common there [y].

6. Flowers two or three at the ends of the branches. Peduncles aggregate, very ſhort, naked. Native of Penſylvania, where it was found by Kalm.

7. Branches round, glaucous. Leaves elliptic, ſmooth on both ſides, on channelled petioles. Peduncles a little ſhorter than the leaves. Native of North America, where it was found by Kalm [z].

8. Native of South Carolina, where it was found by Mr. John Cree. Introduced in 1765. It flowers from may to july.

9. Native of Newfoundland and Labrador. Introduced about 1776, by Benjamin Bewick, Eſq. It flowers in april and may [a].

10. Nerves of the leaves villoſe underneath. Corymbs from a gemmaceous involucre, ſeſſile. Corollas cylindric-ovate, longer than in the others. Stamens ten. Found in North America by Kalm [b].

11. Stem entirely ſmooth. Branches and branchlets alternate, divaricating. Stem-leaves alternate, on very ſhort petioles, ovate, revolute, veined, ſmooth on both ſides, an inch long; on the racemes lanceolate, a line in length. Racemes axillary with the flowers turned one way, ſpreading very much, a finger's length. Bractes on the middle of the peduncle, two, briſtle-ſhaped, length of the peduncle, which is ſcarcely half a line long. Calyx very ſhort. Corolla cylindrical, white. Native of Japan on the iſland of Nipon; flowering in june. Japoneſe name Ki-Fuſi.

12. Stem aſh-coloured, ſmooth. Branchlets alternate, ereſt, villoſe. Branch-leaves ſcattered, ovate, acute, nerved with the nerves all over hiſpid, unequal, from an inch to two inches in length; on the racemes lanceolate, ſmooth, a quarter of an inch long. Racemes at the ends of the branchlets, directed one way, a finger's length. Calyx very ſhort. Corolla red. Native of Japan. In the language of that country Sasjebu [c].

13. Native of North America, where it was found by Mr. William Young. Introduced in 1770. It flowers in may and june [d].

14. Racemes below the leaves, with ſmall oblong bractes. Rediceis longer than the bractes, having two little filiform bractes. Corolla ovate-campanulate. Stamens ten [e]. Native of North America. In-

troduced

troduced in 1770, by Mr. William Young. It flowers in june.

15. Native of North America. Found by Mr. William Young, and introduced in 1770. It flowers in may and june [f].

16. Flowers in alternate numerous racemes, entirely deſtitute of bractes or leaflets; by which mark it is eaſily diſtinguiſhed. Native of Pennſylvania, where it was found by Kalm [g].

17, 18, 19, 20. Natives of North America. The ſeventeenth introduced in 1772, by Samuel Martin, M. D; the eighteenth in 1765, by Mr. John Cree; they flower in may and june. The nineteenth and twentieth were introduced by Mr. William Young, the former in 1770, the latter in 1772. The nineteenth flowers in april and may, the twentieth in may and june [h].

21. Racemes longer than the leaves, ſituated below them, and furniſhed with ovate leaflets [i].

Native of Madeira and the Levant. Introduced in 1777, by Mr. Francis Maſſon. It flowers in june and july [k].

22. Corollas ſeldom five-cleft. Fruit like that of Vitis idæa, and ſapid. It reſembles the preceding; but in that the leaves are annual, the racemes leafy, and the flowers variegated. Native of Jamaica, in the blue mountains [l]. Introduced in 1778, by Thomas Clark, M. D. [m]

23. Leaves on ſhort petioles. Corolla bell-ſhaped; Anthers oblong, yellow, two-horned at the back [n].

The younger Linneus ſays that he placed this plant in the genus Andromeda at the perſuaſion of Forſter; he however has put it among the Vacciniums in his prodromus. It is a native of Otaheite.

24. Roots creeping, woody.] It is of very humble growth, ſeldom riſing above ſix or eight inches high; [and is almoſt herbaceous, but evergreen. Stems moſtly upright, little branched, twiſted or flexuoſe, angular, ſmooth, pliant. Leaves alternate, on footſtalks, obſcurely ſerrate or toothed towards the top, and by no means quite entire as Linneus ſays they are, retuſe, very ſmooth and ſhining above, pale and dotted beneath. Mr. Woodward remarks, that they are furrowed above, with correſponding nerves beneath; and that with the larger leaves much ſmaller ones are intermixed, ſimilar in ſhape: and Mr. Miller that they are ſo like thoſe of the dwarf Box, as to be taken for it, even by perſons of ſkill, at a diſtance. [An elegant drooping cluſter of bell-ſhaped, bluſh-coloured or pale pink flowers terminates the ſtem or branches. But Mr. Curtis obſerves that it is ſeldom found in flower. The flowers do not ſeem to vary from their proper four-cleft form, and eight ſtamens; though Pollich reckons ten; and Krocker ſays there are often ten filaments. Under each flower is a ſingle, elliptic, concave, ciliate bracte. The anthers terminate in a pair of taper points, through a pore at the end of which the pollen is diſcharged, but they have not the lateral horns which are found in ſome of the ſpecies. Dr. Withering remarks, that the floral leaves and calyxes are coloured; the filaments very white and woolly; the anthers red, two-celled, with a yellowiſh tube at the point of each. Berries red, acid, aſtringent and bitter. They are ſcarcely to be eaten raw, and though made into pies in Derbyſhire, where they are called Cow-berries, their flavour is far inferior to the Cranberry. Their beſt uſe is for making a rob or jelly, which is eaten with all kinds of roaſt meat in Sweden, and is far preferable to that of the red currant as a ſauce for veniſon. It is alſo an excellent medicine in colds, ſore throats, and all irritation of the mouth or fauces [o].

Linneus ſays that they are ſent in large quantities from Weſt Bothnia to Stockholm for pickling; that in Switzerland and other more ſouthern parts of Europe they leave them to the birds; and that in upper Tornoa they are found perfectly white.]

Mr. Miller ſays, he has been informed, that in Sweden and Norway this ſhrub is planted for edgings to borders in gardens: and that he has ſeveral times received plants of it from Greenland by the whale ſhips.

[Native of moſt parts of Europe, particularly the northern countries, on dry ſtony heaths or moors, on the mountains. Many places in Derbyſhire, and our northern counties are clothed with this humble evergreen, as alſo in Scotland and Wales. In Ireland, on the tops of all mountains the elevation of which is 500 yards and upwards. It flowers in june, (Dr. Withering ſays, march and april;) and the berries ripen in auguſt [p].

25. Roots perennial, fibrous. Stems ſuffruticoſe, very ſlender, ſmooth, and creeping by means of long fibres. Branches ſcattered, procumbent, leafy, flowering about the upper part. Leaves alternate, erect, on ſhort footſtalks, ſmall, acute, dark ſhining green above, glaucous beneath. Peduncles terminating, aggregate, about an inch long, red, one-flowered, having a few ſcattered or oppoſite bractes. According to Linneus, the raceme is very ſhort, and the peduncles very long, with two alternate bractes on them: but the bractes are not always alternate, and there are ſometimes more than two. Flowers drooping, of a beautiful roſe colour or deep fleſh-colour, ſingularly elegant. Calyx ſmooth, coloured, compoſed of four obtuſe fringed ſegments. Corolla divided to the baſe into four ovate petals, rolled back, and according to Withering falling off ſeparate. Hence ſome have judged this ſpecies to form a genus diſtinct from Vaccinium: but there is no end to thus ſubdividing genera. Filaments flat, downy, ſtanding out above the corolla: anthers deeply cloven, diſcharging the pollen by a hole in each point. Sometimes, according to Mr. Gough, there are ten ſtamens. Style red: ſtigma acute, and an open hole. Berry globular or pear-ſhaped, pale red mottled with purple, when fully ripe purpliſh red.

Theſe berries, made into tarts, are much eſteemed, but on account of a peculiar flavour, are diſliked by ſome. They may be kept ſeveral years, if wiped dry, and then cloſely corked in dry bottles; or the bottles may be filled with water. They are brought to London from the moorland counties, and even imported from Ruſſia; the Cambridge market is ſupplied from Lincolnſhire. At Longtown in Cumberland twenty or thirty pounds-worth are ſold by the poor people each market day for five or ſix weeks together. The Swedes have no idea of putting them to any other uſe than to boil ſilver plate to its proper whiteneſs; the ſharp acid of the Cranberry corroding the external particles of the copper alloy.

Native of Europe, on turfy bogs, moſtly entangled in Sphagnum and other bog-moſſes, which cover the ſurface of ſhallow waters, ſo that thoſe who gather the fruit are obliged to wade in ſearch of it. The flowers come out in june, and the berries ripen in auguſt.

Plentiful in the north of England, in Scotland, and Ireland in their flow bogs. On Derſingham moor near Norfolk, on Bootham moor near Lincoln, and in great quantities in many parts of the county. Gamlingay bogs, Cambridgeſhire; and Potton bogs, Bedfordſhire. Biſhop's woods near Eccleſhall, Staffordſhire; Birmingham heath, &c.

It has many names in Engliſh—Cranberries, Moſs-berries, Moor-berries, Fen-berries, Marſh Worts or Whortleberries, Corn-berries. The moſt general name Cranberry probably originated from the peduncles being crooked at the top, and before the expanſion of the flower, reſembling the head and neck of a crane [q].

26. This has the ſame ſtructure with the European Cranberry, but is bigger in all its parts, and the ſtem is imbricate with briſtle-ſhaped ſcales [r]. It is extremely abundant over all North America, and is called by the Canadian French Atopa, which name they have borrowed from the Indians. They are brought to market every wedneſday and ſaturday at Philadelphia, late in autumn. They are boiled and

prepared in the ſame manner as the Swedes do their red Whortleberries, (Vacc. Vitis idæa;) and they are made uſe of during winter, and part of ſummer, in tarts and other kinds of paſtry. But as they are very ſour, they require a great quantity of ſugar. Quantities of theſe berries are ſent over preſerved to Europe and the Weſt Indies*.

27. The leaves are more oblong in this, and not rolled back at the edge, but flat. The ſtems have not the ſcales upon them, which are found in the preceding ſpecies. Ray ſays, that the berries are ſent to London from New England, that he had eaten them, and that they were uſed for making tarts: but whether they were from this or the former ſort may perhaps be doubted.—It is a native of North America, in boggy grounds; was cultivated in 1760, by Mr. James Gordon; and flowers here in may†.

It is uncertain whether the hiſpidulum of Miller belongs to the preceding, as he has given the character of that from Linneus, and Ray's ſynonym which is attributed to this by Willdenow. See Arbutus thymifolia.

Miller's Vaccinium penſylvanicum, (n. 3.) ſeems rather to be a variety of V. Vitis idæa.] He refers to *Pluk. phyt. t.* 321. *f.* 4. for a figure of it: and deſcribes it as having a low ſhrubby ſtalk, like the Vitis idæa; ſmall ovate pointed leaves, not unlike ſome varieties of the Myrtle, and continuing green all the year; the flowers axillary at every joint, nodding on pretty long peduncles, ſolitary, ſmall, white. Berries red. Native of Virginia and other parts of North America.

PROPAGATION AND CULTURE.

Theſe are ſhrubs or ſhrubby plants, and hardy, (except n. n. 3. 11. 12. 21. 22. 23.) But they are difficult of culture in gardens, becauſe they require a mooriſh or boggy ſoil, which for ſome of the ſpecies muſt be covered with moſs, and conſtantly kept wet.

1 and 24. Vaccinium Myrtillus and Vitis idæa increaſe very faſt by their creeping roots, and when fixed in a proper ſoil will ſoon overſpread the ground. The firſt is frequently found on ſandy heaths, intermixing its roots with Heath; but the other grows only upon mooriſh land.

25, &c. The european and american Cranberries, being natives of bogs, cannot be propagated upon dry land; but on natural or artificial bogs they will ſpread and increaſe, if they are taken up carefully with ſome of the ſoil to their roots, and tranſplanted in autumn. But they can only be cultivated for curioſity in gardens, for they will not thrive much or produce fruit out of their native ſwamps and bogs.

DESCRIPTIONS, *&c.*

1. Root annual. Stem and leaves ſmooth [x]. Leaves four in a whorl; flowers herbaceous; fruit echinate. Native of Italy on the whole coaſt of Tuſcany, eſpecially in dry rocky places; alſo on old walls at a diſtance from the coaſt, as in the Farneſe garden, Diocletian's baths, &c. at Rome [y]. On the ſandy ſhores of the County of Nice: and in the South of France, where Cherler found it about Nemours, and Magnol about Montpellier. Columna firſt diſcovered it near Leghorn.

2. Root annual. Stems hiſpid. Leaves rugged. Fruit rounded, hiſpid all over; not even or beaked. It is nearly allied to V. muralis, but is larger and erect [z]. Stems erect, ſometimes branched at bottom. Leaves ſmall, in fours, elliptic (or wedge-ſhaped,) hirſute, toothletted, on very ſhort petioles. Flowers axillary, in threes; the middle one hermaphrodite, with a four-cleft corolla. Fruit hiſpid, creſted-echinate [a].

[x] Linn. ſyſt. [y] Micheli. [z] Linn. ſpec. and ſyſt. [a] Desfontaines.

Native of the South of Europe, and of Barbary about Algiers.

Theſe two ſpecies were cultivated by Mr. Millet in 1768, and flower in may and june.

3. Native of the Canary iſlands, where it was found by Mr. Francis Maſſon, and introduced in 1780. It is annual, and flowers in july.

4. Native of the Levant. Introduced in 1780 by Monſ. Thouin. It is annual, and flowers in may and june [b].

5. This has the appearance of Galium Aparine. Stem rugged backward, ſcandent. Leaves in ſixes, rugged at the edge. Peduncles the length of the leaves, three-flowered at the top; the hermaphrodite flower ſeſſile, the two ſide ones male and pedicelled, trifid or quadrifid [c].

Stems branched, procumbent, angular; angles toothletted, rough. Leaves moſtly in ſixes, linear, toothed at the edge, blunt with a point. Flowers axillary, in threes. Corolla white. Middle flower four-cleft; the two ſide ones three or four-cleft. Seeds round, wrinkled-papilloſe, thick, ſmooth. It ſhould not be confounded with Galium ſpurium of Linneus, which is very like it, but has the ſeed as ſmall again, a little wrinkled, ſmooth or villoſe [d].

The Aparine ſemine lævi of Vaillant, *t.* 4. *f.* 3. *a. a.* to which moſt authors refer, Aparine ſemine læviore of Ray; which Smith and Withering call Galium tricorne, Hudſon, &c. G. ſpurium, differs from this in having the leaves about eight in a whorl, ſerrate backwards, not rugged at the edge forwards; and the tubercles of the fruit much ſmaller. G. ſpurium of Linneus has only ſix leaves, with the fruiting peduncles from upright ſpreading, twice as long as the leaf, and the ſurface of the fruit even, ſcarcely granular or roughened [e].

The plant which is figured as Valantia Aparine in Flora Ruſtica, is determined by Dr. Smith to be his Galium tricorne.

Valantia Aparine is native of Germany, France, Sicily and Barbary.

6. Root annual. Leaves ſmooth, ſubciliate with the edge rugged: floral leaves ſeſſile, ſubcordate, rolled in at the baſe, after the flower is paſt turned back cloſely and concealing the fruit; when that is ripe the flowering-ſtem with the leaves ſeparates in joints. Native of Egypt, Syria and Barbary [f]. Both theſe were cultivated in 1768 by Mr. Miller, if he has rightly named them, for he gives no deſcriptions.

7. This, with glabra, Aparine, and articulata, belongs more properly to the Galiums. For the deſcription of the preſent ſpecies, See *Galium cruciatum.*

8. Linneus ſays this is very nearly allied indeed to the preceding.—Bauhin, to whom Linneus refers, deſcribes it as having a very ſlender, creeping, jointed root; the little ſtalks tender, jointed, leſs than a palm in height; leaves from each joint four, decuſſated, ſmooth, nerved like thoſe of Plantain, pale green, an inch and half in length; flowers ſmall, yellow, on ſhort pedicels. Common about Bologna the whole ſummer among buſhes.—Scopoli alſo ſays that the flowers are yellow. It ſeems doubtful whether Villars's glabra be the ſame with this; the flowers in his plant being white and ſmall, and the plant itſelf bearing no reſemblance to V. Cruciata.

Native of the South of Europe. Introduced in 1783, by William Pitcairn, M.D. It flowers in july [g].

9. Stem herbaceous, from one to three feet high, looſe, branched, grooved, rugged. Branches oppoſite, numerous, divaricating, ſubdivided, patulous, looſe, hirſute. Leaves in fours, ſeſſile, ſmall, oblong, entire, convex, channelled at the baſe above, hirſute-hiſpid. Flowers peduncled, axillary, ſmall, yellow. Peduncles ſhorter than the leaves or of the ſame length, pubeſcent. Calyx four-leaved, inferior, ſcarcely bigger than the corolla: leaflets ovate with a ſhort point, rough-haired, rugged. Filaments very ſhort. Anthers roundiſh, very minute. Germ ſuperior, minute, two-grooved.

[b] Hort. kew. [c] Linn. ſpec. [d] Desfontaines. [e] Smith brit. 177. [f] Linn. ſyſt. [g] Hort. kew.

Digitized by Google

Style very ſhort. Stigma two-lobed, pellucid. Berries two, connate, fulvous, ſmall, one-ſeeded. Seeds roundiſh, whitiſh, ſhining. Native of Jamaica, in the cool mountains [b].]

PROPAGATION AND CULTURE.

If the annual ſorts are permitted to ſcatter their ſeeds in autumn, the plants will come up, and require no farther care but to thin them, and keep them clean from weeds.

The roots of the ſeventh and eighth ſpread greatly, [and may be eaſily increaſed by dividing them. They are all hardy plants, except the third and laſt.

VALANTIA. See *Galium*.

VALDIA. See *Oviedo*.

VALENTINIA. (*So named by Swartz, probably in honour of* Mich. Bernh. Valentini, *profeſſor of medicine at Gieſſen.*)

Lin. gen. Schreb. n. 1748. *p.* 801. *Swartz prodr.* 63.

Claſſ. 8. 1. Octandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, ſpreading, concave, coloured, five-parted: *ſegments* obtuſe, concave, entire.

COR. none, unleſs the calyx be taken for it.

STAM. *Filaments* eight, awl-ſhaped, erect, a little ſhorter than the calyx. *Anthers* roundiſh.

PIST. *Germ* roundiſh, ſuperior. *Style* length of the ſtamens, round, thick. *Stigma* headed.

PER. *Capſule* berried, roundiſh opening into three or four parts which afterwards roll back, one-celled, pulpy within.

SEEDS four, oblong.

ESSENTIAL CHARACTER.

Cal. five-parted, coloured, ſpreading. *Cor.* none. *Capſ.* berried, four-ſeeded, pulpy.

SPECIES.

1. Valentinia ilicifolia.

Malpighia aquifolii amplioribus foliis. *Plum. ic.* 167. *f.* 2.

Ilex folio agrifolii americana. *Pluk. phyt. t.* 196. *f.* 3.

DESCRIPTION, *&c.*

This is a branching ſhrub, two or three feet high. Leaves alternate ovate-lanceolate an inch and half long, waved and ſpiny at the edge ſmooth and very ſtiff. Flowers terminating, in a ſort of umbel, ſcarlet.

Native of Hiſpaniola, on the moſt barren rocks towards the ocean, and in Cuba about the Havanna [b].

VALERANDI. See *Samolus*.]

VALERIANA. (*According to ſome; named from one Valerius, who is ſaid firſt to have uſed this plant in medicine: or as others, from* valor *or* valentia, *or from* valére. *But all this is uncertain.*)

Lin. gen. n. 44. *Reich. n.* 48. *Schreb. n.* 60. *Tournef. t.* 52. *Vaill. mem. par.* 1720. *Juſſ.* 195. *Gærtn.* 2. *t.* 86.

Valerianella *Tournef.* and *Vaill.* Fedia *Gærtn. t.* 86.

Claſſ. 3. 1. Triandria Monogynia.

Nat. order of *Aggregatæ*. *Dipſaceæ* Juſſ.

GENERIC CHARACTER.

CAL. ſcarcely any. A ſuperior margin.

COR. *Tube* nectariferous on the lower ſide, gibbous. *Border* five-cleft. *Segments* obtuſe.

STAM. Three or fewer, (in one ſpecies four). *Filaments* awl-ſhaped, erect, length of the corolla. *Anthers* roundiſh.

PIST. *Germ* inferior. *Style* filiform, length of the ſtamens. *Stigma* thickiſh.

PER. A cruſt not opening, deciduous, crowned.

SEEDS ſolitary, oblong.

OBS. *A wonderful diverſity of the parts of fructification is obſerved in this genus; as to their number and form in the different ſpecies: for inſtance,*

The margin of the calyx is ſcarcely obſervable in ſome, but is five-cleft in others.

The tube of the corolla in ſome is oblong, in the two firſt

[b] Swartz. [1] Willd. from Swartz.

it is furniſhed with a melliferous ſpur, in others it is very ſhort. The border in ſome is equal, in others two-lipped with the upper lip bifid.

Stamens in moſt three, in ſome two or one only, in the Siberian ſpecies four; in others the ſexes are diſtinct.

Stigma, in ſome trifid, in others emarginate, in others globular.

Pericarp, in ſome ſcarcely any, in others a thick capſule, in others two-celled.

Seeds in ſome crowned with down, in others without any, and of various forms.

ESSENTIAL CHARACTER.

Cal. none. *Cor.* one-petalled, gibbous on one ſide of the baſe, ſuperior. *Seed* one.

SPECIES.

Flowers three-ſtamened, ſtem dichotomous, lower leaves toothed, upper linear multifid.]

DESCRIPTIONS, &c.

1. Roots perennial, woody, as thick as a man's finger, ſpreading very wide. Stems about three feet high, round, ſmooth, grayiſh, hollow. At each joint two (ſometimes three,) ſmooth, ſpear-ſhaped leaves, near three inches long, and an inch broad. The upper part ſends out branches by pairs, which, with the principal ſtem, are terminated by red flowers growing in corymbs.

[The whole herb is very ſmooth and even. The upper leaves are ovate and very long pointed. The flowers are diſpoſed in a denſe and very branching corymb; they are ſlender, make a good appearance, and are uſually of a deep roſe colour; but vary to pale fleſh-colour and white [k]. Pericarp none, except the cruſt over the ſeed ſpringing from the calyx. Seed inferior, ovate, narrowed upwards, compreſſed a little, having a ſingle depreſſed ſtreak on one ſide, and three ridges on the other, ruſeſcent: down ſeſſile, longer than the ſeed, compoſed of about twenty incurved feathered rays, united at the baſe into a membranaceous inverſely conical cup [l].

Native of France, Switzerland, Italy, the Levant and Barbary. In England on walls, but probably eſcaped by means of its downy ſeeds, from gardens. Gerarde ſays it grew plentifully in his garden, being a great ornament to the ſame, and not common in England. Parkinſon, that it grows in our gardens chiefly, for we know not the natural place of it. It is not acknowledged as an Engliſh plant by Ray, nor by Dillenius. I have a ſpecimen with a white flower from Ely Minſter, gathered there by Profeſſor John Martyn above ſeventy years ago; and I found it growing abundantly with a red flower on Merton Abbey walls in Surry, on the twenty-third of Auguſt 1758. Mr. Hudſon ſays it is frequent in Devonſhire and Cornwall, both among rubbiſh and on walls. Mr. Relham remarks it to grow at Coton and Babraham, as well as on Ely Minſter and the walls adjoining, where I alſo have frequently ſeen it. Dr. Sibthorp obſerved it on Merton College walls, Oxford; and Dr. Smith in Biſhopgate-ſtreet, Norwich. It flowers all the ſummer and autumn, from the end of may.]

2. The root of this is not ſo large as that of the preceding ſort. Stems two feet high or more, branching on each ſide from the root to within ſix inches of the top. Leaves three or four inches long, but as narrow as thoſe of flax. Upper part of the ſtem naked, and terminated by a compact corymb of bright red flowers, ſmaller than thoſe of the former.

[It ſeems to be very diſtinct from the common Red Valerian, in having very narrow linear leaves. Native of the mountains of France, Switzerland, Italy and Barbary. Cultivated by Mr. Miller before 1743.]

3. This is an annual plant. The lower leaves, which ſpread on the ground, are cut into many obtuſe ſegments; the ſtalks, when the plants are in good ground, will riſe near a foot and half high, but upon dry ſtony ſoils not half ſo high, and when they grow out of the joints of old walls, not more than three inches in height: they are hollow, ſmooth, and round, ſending out branches by pairs from the upper joints. The ſegments of the pinnatifid leaves are very narrow. Stem and branches terminated by tufts (corymbs) of flowers ſhaped like thoſe of the Garden Valerian, but ſmaller and tinged with fleſh-colour at the top.

[Stem upright, ſometimes unbranched. Leaves very ſmooth; the lower ones ſmaller, on a long channelled petiole, ovate, obtuſe, entire or with unequal blunt teeth; the middle and upper ones pinnatifid, with toothed pinnules. Flowers corymbed, then panicled, directed one way, ſeſſile on dichotomous branchlets. Bractes awl-ſhaped, preſſed cloſe. Corolla ſmall, pale roſe-coloured. Seed oblong, compreſſed, attenuated upwards, ſtriated, crowned with a feathered down. It varies with the lower leaves pinnatifid; and flowers early in the ſpring [m].

Native of the South of France, Italy, Portugal, the Levant, and Barbary. Cultivated by Mr. James Sutherland in 1683 [n].

4. Root perennial, jointed, creeping, the thickneſs of a crow-quill, white, but ſometimes tinged with red. Stems from a ſpan to a foot or a foot and half in height, upright, grooved, ſmooth. Leaves next the root ovate, petioled, undivided. Stem-leaves few, oppoſite, pinnatifid or lyrate pinnate, ſmooth, generally entire, but ſometimes toothed or obtuſely ſerrate; the end lobe or leaflet large and ovate in the lower ſtem-leaves, ſmaller and lanceolate in the upper ones. Flowers forming a kind of corymb, or rather cymoſe panicle, and having a tinge of red, but paler in the female flowers; theſe alſo are much ſmaller and in cloſer corymbs: the male flowers are conſiderably bigger and more looſely diſpoſed; and the male plant is leſs and more tender. In the male flowers the filaments are longer than the corolla; the anthers, white or pale red; and ſometimes there is a ſhort minute piſtil in the centre: their number varies from one to four, but is uſually three. The female flowers have the germ ovate, flat, grooved, nearly the length of the corolla; the ſtyle white, ſomewhat thickened near the top, a little longer than the corolla, oblique; and the ſtigma trifid: ſometimes imperfect rudiments of ſtamens are viſible within the tube of the corolla. Seed ovate-oblong, pale brown, with a ſingle rib on one ſide, and three ribs on the other, crowned with a feathery down. Dr. Withering ſays, that in Portugal he obſerved female flowers producing perfect ſeeds, on the ſame plant with the male flowers. Scopoli affirms that he never ſaw any plants truly dioecous, or without perfect ſeeds. That is certainly not the caſe in England.

This ſpecies with us is pretty regularly dioecous; or if there be any hermaphrodite flowers, they are ſuch in ſtructure only, both organs not being perfect [o].

Native of Europe and the Levant, in wet meadows, marſhes, and by the ſide of ditches and ſtreams; flowering in may and june.

The roots have the ſame ſmell with the officinal and garden Valerian, and have like properties with them, but in a much weaker degree than the former.

5. Found at the Cape of Good Hope by Thunberg.]

6. Root perennial, compoſed of long fleſhy ſlender fibres, uniting in heads, [and ſending out from its crown one or more long-extended creeping ſhoots. Stems in dry ground from one foot to two feet in height, but in woods and hedges, moiſt ground, and gardens four or five feet high, upright, round, grooved, hollow, in ſome parts more or leſs hairy, terminating in flowering branches which are brachiate or diſpoſed croſſwiſe. Leaves oppoſite, connate, bearded at the baſe on the under ſide, all pinnate; the midrib ſomewhat downy; the pinnæ or leaflets eleven to thirteen, almoſt all equal, oppoſite or alternate, ſlightly decurrent, unevenly and diſtantly toothed, veiny, wrinkled, paler on the under ſide, ſlightly hairy, the terminating leaflet three-lobed not bigger than the others: the lower leaves on long petioles, the upper ones nearly ſeſſile; the uppermoſt on the flowering-branches trifid, and ſometimes entire. Flowers in a kind of corymb, of a pale fleſh-colour, and having a ſingular odour. Flower-ſtalks much branched, and many times divided. Bractes lanceolate, acuminate, connate, whitiſh, with a green midrib. Calyx only a ſlight margin on the top of the germ. Filaments longer than the corolla, bending back when the anthers have ſhed their pollen; anthers of the ſame colour as the flower. Germ conic: ſtigma obtuſe, white, and trifid. Seed ovate-oblong, compreſſed, furniſhed with a pappus or down, having twelve feathery rays, of a purpliſh colour at the baſe [p].

[k] Smith brit. [l] Gærtner. [m] Desfontaines. [n] Hort. kew. [o] Curtis, Smith brit. Withering. [p] Curtis, Smith brit. Relh.

Digitized by Google

Native of Europe and Siberia; in woods, hedges, marſhes, and near rivers: it alſo grows among buſhes in high paſtures and on dry heaths, and is then much ſmaller and more hairy, with the leaves narrower, and the roots more highly aromatic and leſs nauſeous. It flowers in june.

The root has a ſtrong, and to moſt people a diſagreeable ſmell; its taſte is warm, bitteriſh and ſubacrid, communicating its properties to wine, water, and ſpirit; but it is beſt in ſubſtance, and may be taken from half a dram to two drams for a doſe. There is no doubt of its poſſeſſing antiſpaſmodic virtues in an eminent degree. It is often preſcribed with advantage in hyſterical caſes; and inſtances are not wanting where it appears to have removed ſome obſtinate epilepſies. In habitual coſtiveneſs it is an excellent medicine, and frequently looſens the bowels, when other ſtronger purgatives have been tried in vain [s].

The unpleaſant flavour of Valerian is beſt concealed by a ſmall addition of mace. A tincture of the root in proof ſpirit, and in volatile ſpirit, are ordered in the London Pharmacopœia. Dr. Cullen ſays, that if it has ſometimes failed, it is from the diſeaſe depending upon different cauſes, or the root being frequently employed in an improper condition, or in doſes not large enough [t]. I have known very great effects produced in hyſterical caſes by Valerian; but then the root was procured from dry calcareous paſtures, and it was given in conſiderable quantities during a long time.

It is well known that cats are much delighted with the roots. Dr. Stokes informs us that rats are equally fond of them, and that rat-catchers employ them to draw the rats together.]

7. Roots thick, fleſhy, jointed, ſpreading near the ſurface in a very irregular manner, croſſing each other, and matting together by their ſmall fibres. Many of the root-leaves entire, others divided into three, five, or ſeven, obtuſe lobes, of a pale green and quite ſmooth. Stems three or four feet high, hollow, ſending out lateral branches by pairs. Stem-leaves oppoſite at each joint, compoſed of four or five pairs of long narrow leaflets, terminated by an odd one. Stem and branches terminated by corymbs of ſmall white flowers. Seeds oblong, flat, with a pappus or downy crown.

[Linneus remarks, that this differs from the officinalis, in not having the ſtem grooved, and the outer leaflets being larger than the others.—The root-leaves are on long petioles oblong, glandular at the edge and ſometimes ſlightly crenate. Petiole channelled. Stem-leaves remote; the lower ones often two-lobed or three-lobed, the middle and upper ones pinnate: pinnules lanceolate, acute, quite entire, except the end ones, which are ſometimes toothed. Stem upright, ſmooth. Bractes linear-ſubulate. Segments of the corolla oblong, obtuſe, crenulate. Stigmas three [u].

Native of Alſace, Sileſia, Dauphiné, Barbary near La Calle: flowering from may to july. Gerarde, in 1597, ſays it was then planted in our gardens.

The odour of the flowers is very pleaſant, whereas that of the officinal Valerian is rather diſagreeable. The root has the ſame ſmell, taſte, and qualities with that, but is inferior to it as a medicine, at leaſt with us. Where it grows wild, it may perhaps be as good.

8. Root perennial, long, unequal, browniſh, ſtrong-ſmelling. Root-leaves oblong-cordate, bluntiſh, ſmooth, obtuſely ſerrate-toothed, on long petioles: the two firſt of theſe that come out are more inclined to roundiſh, and are only ſlightly crenate. Stem upright, undivided, about a foot high. Stem-leaves two or three pairs, ſmooth, ternate, on ſhort petioles: leaflets confluent at the baſe, lanceolate, acute, unequally ſubſerrate, the middle one larger than the others: they vary much, being gaſh-ſerrate, crenate, or even quite entire; the uppermoſt are ſometimes lanceolate-linear and quite entire, ſometimes pinnate with five leaflets. Flowers numerous, white, in looſe corymbs. Seeds downy [x].

Linneus remarks, that the proper involucres are two-leaved and briſtle-ſhaped.—And Villars, that the roots are thick, woody, and creeping, forming conſiderable tufts on the rocks; and that the leaves are of an aſh green or glaucous.

Native of the Alps of Switzerland, Auſtria, Carniola, Dauphiné and Piedmont; flowering all the ſummer. —With us it flowers from march to may; and was cultivated by Mr. Miller in 1739 [y].

9. This agrees in ſtature and habit with the preceding; but this is more tufted, and has the root commonly creeping horizontally, more divided, and not ſmelling ſo ſtrongly. All the leaves are acute, unequally ſerrate or toothed and ſmooth; the root-leaves are on long petioles, and are more or leſs attenuated at the baſe towards the petiole; the ſtem-leaves vary in number, are on ſhort petioles, and rather oblong. Stem upright, ſimple, a foot or eighteen inches high. Flowers in a corymb, whitiſh or purpliſh. Seeds downy [z].

Scopoli remarks, that the lower leaves are oval and blunter; the upper ones oblong-acuminate, toothed; the uppermoſt ſubſeſſile: and that the leaves being always ſubdivided, is a ſufficient diſtinction of this from the preceding.

Native of the mountains of Switzerland, Auſtria, Carniola, Dauphiné, Piedmont, Sileſia, Siberia: flowering there all the ſummer.—With us it flowers in june and july; and was cultivated by Mr. Miller in 1739 [a]. Theſe two ſpecies were in the ſecond volume of Mr. Miller's Dictionary publiſhed in 1739. He had nineteen ſpecies there, beſides ſeven ſpecies of Valerianella: many of which are omitted in the later editions of the Dictionary.

Villars has a ſpecies, which he names rotundifolia, but ſuſpects that it may be a variety of this. He remarks that the montana is of a ſize between the tripteris and this; that it is greener than the firſt; but leſs green than the ſecond; that the leaves are all petioled, and that there are three or four pairs on the ſtem; that the petioles of the root-leaves are ſhorter, and that it does not form tufts like the rotundifolia, that the flowers alſo are more widely ſeparated, and the ſtem-leaves terminated by a lengthened point.

The rotundifolia is the leaſt of the three, and its flowers approach a little to thoſe of the elongata; but the leaves differ too much for it to be a variety of that: it has rarely any deep diviſions in them, or even earlets at the baſe of the ſtem-leaves, any more than in the montana; whilſt the tripteris has them ſometimes entire. Theſe three ſpecies are very nearly allied, and the varieties of montana and tripteris are diſtinguiſhed with difficulty, whereas the rotundifolia is eaſily known by its large tufts, numerous green leaves, and low ſtems.

10. Root perennial, black, oblique, with long fibres, ſmelling very ſtrong, aromatic, cauleſcent at top and ſcaly with the remains of the deciduous leaves. It is often in tufts with an upright ſtem, four or five inches high. All the leaves are quite entire and obtuſe; the root-leaves ſubovate, and attenuated into the petiole at the baſe; ſtem-leaves two, oppoſite, linear and ſeſſile, about the middle of the ſtem, but there are ſometimes none. Stem ſlender, ſimple, terminated by a few ſmall whitiſh flowers in a corymb. Seeds downy [b].]

It is a very humble plant, the ſtalks trailing upon the ground among the moſs, and putting out roots at their joints, which ſwell into knobs or tubers. The flower-ſtalks riſe three or four inches high, and have two or three pairs of ſmall ovate leaves. The flowers are ſmall, of a pale fleſh-colour, in a looſe ſeſſile corymb. It flowers in june.

Mr. Miller had it from Dr. Allione, who gathered it on the alps near Turin: [that author ſays that it is ſtronger than the officinal ſpecies. It is found alſo in Switzerland, Auſtria and Carniola; and cultivated by Mr. Miller in 1739.

11. Roots perennial, and tuberous, by which it is eaſily diſtinguiſhed; there is a variety which has them longer; the plant is larger, and the leaves more cut and of a cinereous green; the other is greener, ſmaller, leſs cut, and the roots in form of an olive [c].

Accord-

Digitized by Google

According to Linneus, the ſtem-leaves have two pinnas on each ſide; whereas the preceding has two linear obtuſe ſtem-leaves, and the flowers in whorls. —This is native of the ſouth of Europe, and was cultivated in 1739 by Mr. Miller. It flowers in may and june [b].

12. Root perennial, blackiſh, with numerous and long fibres, covered with the remains of leaves, having the ſmell and taſte of officinal Valerian, but much more unpleaſant and acrid, and leaving a bitterneſs on the tongue. The whole plant is ſhining, and about half a foot high. Root-leaves ſubovate, cut with few teeth, ſometimes quite entire, blunt, three-nerved, thickiſh, almoſt inſipid, attenuated into the petiole. Stem-leaves one pair, below the middle, linear or oval-linear, obtuſe, quite entire or ſometimes having a few teeth, almoſt an inch long, with ſometimes a common peduncle from each axil. Stem ſimple, roundiſh, ſubdivided at top. The common peduncles are not more elongated in the flowering plant than in other ſpecies. Flowers white. Seeds downy [c].

According to Monſ. Villars, the nerved pointed leaves, and higher ſtems terminated by long racemes of flowers, ſufficiently diſtinguiſh this ſpecies from the celtica.

Native of the mountains of Stiria, Auſtria, Sileſia, Dauphiné and Piedmont.

13. Root perennial, with fewer fibrils, dirty white, having little taſte or ſmell. It is a ſhining upright plant, with a ſimple ſtem half a foot or a ſpan in height. Root-leaves ovate, quite entire or ſometimes ſlightly toothed, blunt, on long petioles, attenuated at the baſe, thickiſh. Stem-leaves two or three pairs, ſeſſile, embracing, reſembling the root-leaves, but deeply cut or gaſh-haſtate. Raceme terminating, erect, long; with the pedicels oppoſite, dichotomous, ſhortiſh. Or as Jacquin deſcribes it, all the common peduncles at diſtances oppoſite, ſix on each ſide, corymbed, divided at top into two or three others, many times ſhorter than the primary common peduncle, forming, not a corymb or cyme, but a long pyramid, which riſing from the upper leaves takes up half the height of the plant. Bractes linear. Corolla ſmall, duſky, regularly five-cleft [d].

Scopoli ſays it differs from montana by its radical gem, panicled ſtalk, and leaves under the firſt racemes moſtly trifid: —from tripteris, by its leaves toothed all round; the ſtem-leaves ovate, the root-leaves always longer than the petiole.

Native of the mountains of Lower Auſtria; flowering in july.]

14. Root perennial, fibrous, from which come out many heart-ſhaped leaves, on petioles more than a foot in length; they are four inches over each way, bluntly ſerrate, ſmooth, and of a bright green on their upper ſurface, but pale and a little hairy underneath. The ſtalks riſe three feet high, are hollow, channelled, and ſend out oppoſite branches towards the top. Stem-leaves oppoſite, ſhaped like the lower ones, but a little pointed; and frequently at the top there are ternate leaves ſtanding upon ſhort foot-ſtalks. The ſtem and branches are terminated by umbels of pale fleſh-coloured flowers, having very ſhort ſpurs. Seeds downy. It flowers in june; and the ſeeds ripen in auguſt. Native of the Pyrenees. [Cultivated in 1692, by Charles Dubois, Eſq. [e]

15. Panicles axillary. Down feathered. Native of Spain [f].

16. Found about Montpelier.

17. Root perennial. Plant ſmall, ſcarcely bigger than a Daiſy, even when cultivated. Root-leaves obovate, petioled, quite entire: ſtem-leaves lanceolate, ſeſſile. Corymb terminating, made up of oppoſite peduncles. Involucre ſix-leaved, linear, three-flowered [g].

Ray firſt obſerved it on mount Saleve near Geneva. It was found about the ſame time by Barrelier in Italy. Arduini and Allione have ſince found it in Italy, and Wulfen in Carinthia and the Tyrol.

[b] Hort. kew. [c] Jacqu. vind. [d] Linn. ſpec. & Jacqu. vind. [e] Hort. kew. [f] Loefling. [g] Linn. mant.

18. Root fibrous. The whole ſtem, leaves, and panicle, denſely hirſute. Stem ſimple, upright, a foot high. Root-leaves petioled, aggregate, ovate, earlyrate, a hand long: two lobes in the middle of the petiole, alternate, linear, entire, a line in length, often wanting; two other eared lobes at the top of the petiole, oppoſite, ovate, toothed, half an inch long; terminating lobe very large ovate, unequally gaſh-ſerrate, nerved, an inch wide, two inches long: ſtem-leaves ſeſſile, oppoſite, ovate, acute, gaſhed or ſublyrate, toothed, half an inch long. Petiole compreſſed, widening gradually into the leaf. Flowers axillary and terminating, panicled. Panicle trichotomous, compound. Bractes linear. Corolla ſubrotate, yellow. Anthers ovate, twin. Style ſhorter than the ſtamens. Stigma cup-ſhaped. It differs from ſibirica by its eared leaves, and the hairineſs of the whole plant. Native of Japan, in Jedo, Nagaſaki, &c. flowering in ſeptember and october [h].

19. Root perennial. Stem aſcending, roundiſh, ſtriated, ſmooth. Leaves oppoſite, unequally pinnate with nine or eleven leaflets, which are oppoſite, decurrent, linear-lanceolate, bluntiſh, quite entire except that the terminating leaflet is ſometimes toothed a little, the lower ones ſmaller, ſmooth. Stipules none except a few ſmall ciliate intrafoliaceous hairs. Spike terminating, erect, compound, brachiate, many-flowered: compoſed of many ſpikelets, which are oppoſite with a pair of leaflets at the baſe which are ciliate at bottom, acute, in whorls, the terminating one a little bigger than the reſt: whorls many, from ſix to ten-flowered, decuſſated, ſupported by numerous, ovate, acute, ſubcarinated, ſmooth bractes. Calyx only a ſcarcely viſible rim to the germ. Corolla white, ſcarcely gibbous at the baſe, with an equal border, ſhorter than the tube; ſegments ſubovate, obtuſe, three nerved. Filaments a little longer than the corolla: anthers roundiſh, incumbent. Germ oblong, ſmooth: ſtyle ſhorter by half than the ſtamens, ſubclavate, pale: ſtigma ſmall, bluntiſh. Seed oval, ſeeming to have no down. This ſpecies may be diſtinguiſhed by its peculiar inflorescence, approaching to that of the ſpiked Mints. Found in watery places at Buenos Ayres in America by Commerſon [i].

20. Root annual. Native of Siberia.

21. Root perennial. Native of Siberia. Willdenow has diſtinguiſhed this ſpecies from the preceding at the perſuaſion of Pallas. Mr. Miller has thus deſcribed his ſibirica.] Root biennial. Leaves pinnatifid: lobes of the lower ones oblong, oval, ending in roundiſh points. Stems a foot high. Stem-leaves oppoſite, ſeſſile, ſmooth, of a pale yelloviſh colour; they have four or five pairs of lobes terminated by a broad one, which is cut into three or five points. The upper part of the ſtem has two pairs of branches; the lower pair near three inches long, the upper one not half that length: theſe and the principal ſtem are terminated by bright-yellow flowers, collected in a ſort of umbel. They appear in july; and the ſeeds ripen in autumn. [Cultivated in 1759, by Mr. Miller [k].

22. Root perennial, tufted. Stems a foot high, upright, round, ſmooth. Leaves groſsly toothed eſpecially towards the baſe, ſucculent: the root-leaves on long petioles, oval, obtuſe; the ſtem-leaves ſmaller, ſubſeſſile, oppoſite, obovate. Stipules none. Flowers in a terminating, trichotomous, many-flowered cyme. Bractes at each branch oppoſite, lanceolate, acute, ſomewhat membranaceous. Partial peduncles once dichotomous, with one ſeſſile flower at the diviſions; then racemed, ſimple, from three to five-flowered: flowers ſeſſile, bracteolate, upright and directed one way. Corolla purple: border almoſt regular; ſegments obtuſe, concave. Filaments a little longer than the corolla: anthers ſubcordate. Germ ovate-oblong, curved, ſmooth: ſtyle club-ſhaped, of the ſame length with the ſtamens: ſtigma ſimple, obtuſe. Seed ſcaroely ſtriated, crowned with ſmall teeth. Found by Commerſon in the Straits of Magellan [l].]

23. Root annual. Stems pretty thick, channelled,

[h] Thunberg. [i] Smith. [k] Hort. kew. [l] Smith.

of

Digitized by Google

of a purpliſh colour, eight or nine inches high. At each joint is a pair of ſmooth leaves, of a lucid green, an inch and half long, and an inch broad. From each ſide of the ſtem ſpring ſlender branches; but the upper part divides into two ſpreading branches like the others. The joints are ſwelling and theſe branches divide again by pairs: theſe are terminated by cluſters of red flowers, ſhaped like thoſe of the red Valerian, (n. i.) but larger: there are two embracing leaves cloſe under the bunches. When the flowers are paſt, the fruit ſtretches out in ſhape of a cornucopia.

[Stem hollow, ſtriated, ſmooth, procumbent, dichotomous, with the peduncles very much thickened. Leaves very ſmooth, ſomewhat fleſhy: the lower ones ovate-oblong, obtuſe, decurrent; the upper ones ſeſſile, ovate. Flowers aggregate, terminating, ſeſſile. Bractes awl-ſhaped. Calyx margined, when the fruit is ripe pitcher-ſhaped. Corolla the ſame ſize as in V. rubra, and ſubbilabiate: ſegments unequal, obtuſe: tube gibbous at the baſe, but not ſpurred. Stigmas three, very ſmall. Seed oblong, cloſed and crowned by the calyx[m].

According to Gærtner, who has adopted Adanſon's name of Fedia, for theſe ſpecies which have no feed-down; the fruit is a capſule nearly of a parallelopiped form, compreſſed, a little fungoſe, crowned with the halved three-toothed calyx, ſlightly concave on one ſide, flattiſh on the other, having a raiſed line running along the middle on each ſide: the ſpurious cells very narrow, and almoſt obliterated. Seed ovate-acuminate, compreſſed, without any albumen: embryo inverted, yellow.

Native of Spain, Italy, Sicily, Armenia, Barbary. Cultivated by Gerarde in 1596. It flowers here from may to auguſt[n].

24. Root annual. Stem dichotomous. Leaves lanceolate, ſeſſile, bluntly toothed. Flowers from the diviſions, ſolitary, ſeſſile. Fruit linear three-toothed at the tip; the outer tooth larger and recurved. Corolla regular, white. Stigma trifid. The upper flowers are digeſted into dichotomous, coadunate, obtuſe ſpikes, with the bractes and peduncles thickened; as if it were produced from V. Locuſta as a mother, and V. Cornucopiæ as a father[o].

Native of Italy, the ſouth of France and Barbary, in ſhady places.

25. Root ſmall, annual, fibrous, pale brown. Stem dichotomous, ſomewhat ſpreading, from four inches to a ſpan, and even a foot or more in height, (in gardens;) round, grooved, or angular, tender, often tinged with purple on one ſide. Leaves glaucous, pale, obovate-lanceolate or rather linear-tongue-ſhaped. Bottom-leaves many, uſually entire but ſometimes very ſlightly toothed near the baſe, ſomewhat ſpreading, rather ſucculent, ſmooth, veiny, and a little wrinkled, from three quarters of an inch to two inches in length. Stem-leaves oppoſite at each ſubdiviſion, ſeſſile, remote, uſually more toothed than the bottom leaves: both theſe and the ſtem are ciliate or fringed at the edges with fine white hairs. The flowers are very ſmall, of a pale blueiſh colour, and collected into a cloſe little corymb, protected by an involucre[p]. There is one ſeed to each flower. Gærtner calls it a capſule, which he deſcribes as ſubglobular, crowned with the calyx, which is obliquely truncate and unequally three-toothed, on one ſide twin by a groove along the middle, on the other ſide marked with three filiform ſtreaks, three-celled, valveleſs; two of the cells inflated and barren, the third contains the ſeed, which is ovate-acuminate, compreſſed, tranſverſely wrinkled, of a pale yellow or browniſh colour.

Native of Europe and Barbary, in corn fields, on banks, and under hedges: flowering in april and may.

Early in the ſpring, and even during the greateſt part of a mild winter, this little plant will furniſh a tolerable material for ſalads. Dr. Withering ſays, the tender leaves are little inferior to young lettuce; but Mr. Miller obſerves] that having a ſtrong taſte which is not agreeable to many palates, it is not ſo much in uſe as it was formerly.

[m] Desfontaines. [n] Hort. kew. [o] Linn. ſpec. [p] Fl. ruſt. Curtis, Smith.

[Gerarde, who ſays it may be called from the Dutch *White Pot-herb*, informs us, that ſince it hath grown in uſe among the French and Dutch ſtrangers in England, it hath been ſown in gardens as a ſalad herb. The French call it *Salade de Pretre*, from its being generally eaten in lent. Being common in corn fields, and appearing about the time when lambs are dropped, it has obtained in Engliſh the names of *Corn Salad*, and *Lamb's Lettuce*[q].

β. There is a variety of this, which is ſmaller and has jagged leaves. Ray gives it as a different ſpecies. Several others which Linneus conſidered as varieties, are here given from Willdenow as diſtinct ſpecies.

26. This differs from the preceding in having the ſtem higher and more divaricating, the panicle dichotomous repeatedly, with a flower ſeſſile at each diviſion, and in the ſtructure of the fruit, which is ovate, gibbous and poliſhed on one ſide, navelled on the other, with very unequal teeth at top. It varies with the leaves toothed a little. Native of Germany, France, Italy, and England, among corn[r]. Found in Cornwall by Mr. E. Forſter, jun. in 1799[s].]

27. Stems ſix or eight inches high. Leaves much narrower than in the *olitoria*, ending in acute points and ſerrate. Flowers like thoſe of the common ſort, but having a ſwollen bladdery calyx incloſing the ſeed. [This has ſix briſtle-ſhaped teeth, bent in; and the involucrets are five-leaved and three-flowered[t]. Native of Crete or Candia, and of Barbary.]

28. Bottom leaves three or four inches long, round-pointed, and deeply notched on their edges. Stem near a foot high, ſending out branches by pairs from the joints below. Flowers in globular heads, of an herbaceous white colour.

[Capſule, according to Gærtner, coriaceous, villoſe, inverſely pyramidal, three-cornered, ſcored with a deep groove, crowned by the calyx, which unfolds into a membranaceous circle variouſly and unequally toothed: ſpurious cells narrow; the fertile one twice as wide, and compreſſed. Seed ovate-acuminate, ſmall; without any albumen: embryo inverted, whitiſh. Native of the South of France, Italy, Portugal, and Barbary. This and the preceding were cultivated by Mr. Miller in 1739.

29. Root-leaves ſucculent, narrow, little gaſhed, ſpreading on the ground. Stem half a foot high, ſolid, brachiate at top: having a pair of leaves at each joint, embracing the ſtem, and having three or four deep gaſhes. Flowers in terminating cluſters, ſmall, purpliſh-white. Seeds having a cartilaginous crown with ſix rays. Native of Portugal on the borders of fields[u].

30. Native of North America.

31. This is a ſmall plant, ſcarcely three inches high; found about Montpelier[x].

Theſe from n. 23. are annual, as are alſo the third and twentieth ſpecies; the reſt are perennial.

Linneus has conſidered all the ſpecies from n. 25. to the end as varieties of one only: they are not changed by culture, and when raiſed from ſeed preſerve their ſeveral appearances. The Fediæ with a three-celled fruit, not downy, deſerve to make a ſeparate genus, in the opinion of ſome.

Moſt of the ſpecies have three ſtamens: but n n. 1. 2, 3, have one ſtamen; n. 23. has two ſtamens; and n n. 17, 18, 20, 21. have four.

The uſual colour of the Corolla is either white or red. White in n n. 7 to 13, 17, 19, 24, 28. Red in n n. 1 to 4, 6, 14, 22, 23. Some of the Whites are tinged with red; and ſome of the Reds are only partially ſo, or very pale. N n. 18, 20, 21 are yellow: and 25, 26, 27 have a blueiſh tinge.]

PROPAGATION AND CULTURE.

1. 2. Part the roots in autumn; or ſow the ſeeds ſoon after they are ripe, in a ſhady border; where they will ſometimes come up the ſame autumn, eſpecially if the ſeaſon prove moiſt, otherwiſe they will not appear till the following ſpring. When the plants are fit to remove, tranſplant them into beds, at about nine

[q] Fl. ruſt. Curtis. [r] Willdenow. [s] Smith brit. [t] Linn. ſyſt. [u] Moriſon. [x] Linn. ſpec.

inche

inches or a foot aſunder: water them, and keep them clean; and in autumn tranſplant them where they are to remain.

Theſe plants grow large, and therefore are not proper for ſmall gardens. When the ſeeds light on joints of old walls or buildings, the plants will thrive as well as in the ground, and will continue much longer; the ſeeds therefore may be ſcattered on grottos and rock-work, where the plants will flower from may till the froſt ſtops them, and make a good appearance.

3. This will increaſe by its downy ſeeds without care.

6. Part the roots in ſpring or autumn, and plant them upon a dry, freſh, undunged ſoil, in which, though the roots will not make near ſo great progreſs as in a rich moiſt ſoil, yet they will be much preferable to them for uſe. The roots ſhould be taken up when the leaves decay in autumn, and preſerved dry until uſed. But the roots which grow wild upon dry chalky ſoils are much preferable to thoſe which are cultivated in gardens; which is the caſe with all the aromatic plants.

7. Cultivate the garden Valerian in the ſame way. The plants ſhould be ſet about two feet aſunder in the beds, for they ſpread and multiply very faſt. If the ſeaſon be dry, they muſt be watered until they have taken root.

8 to 13. The Alpine ſorts are difficult to preſerve in gardens; naturally growing on rocks covered with moſs, where the ſnow continues ſix or ſeven months; they require therefore a cold ſituation and ſtony ſoil.

14. This delights in ſhade and a moiſt ſoil. Sow the ſeeds on a ſhady border ſoon after they are ripe, and when the plants come up, treat them as directed for the firſt ſort.

20, 21. Sow the ſeeds where the plants are to remain, either in autumn, ſoon after they are ripe, or in the ſpring. When the plants come up, thin them where they are too cloſe, and keep them clean from weeds.

25. When this is cultivated as a ſalad herb, ſow the ſeeds in autumn, on the ſpot where they are to remain. If they are ſown at the end of Auguſt, the firſt rains will bring up the plants; they ſhould be hoed, to thin them where they are too cloſe, and to deſtroy the weeds. Early in the ſpring the plants will be fit for uſe; and the younger they are when uſed, the leſs ſtrong will be their taſte. The ſeeds will lie in the ground many years, when they happen to be buried deep; and upon being turned up to the air, the plants will come up as thick as if the ſeeds had been newly ſown.

23, 24, 26, &c. Sow the ſeeds in autumn, where the plants are to remain. When they come up thin them and keep them clean. The plants which riſe in autumn, will live through the winter, and come early to flower in the following ſummer, ſo as to produce good ſeeds; whereas thoſe which riſe in the ſpring, do not ripen their ſeeds unleſs the ſeaſon prove warm.

DESCRIPTIONS, &c.

1. This is an aquatic plant, with long, thin, almoſt tranſparent leaves, with parallel nerves and plaits dividing it tranſverſely, very finely ſerrate at the end and floating on the water. The male flower is very ſmall and white, and is borne on a very ſhort ſcape at the bottom of the water: when it is mature it breaks looſe, and floats on the ſurface. The female flower, which is larger and purple, grows on a ſpiral ſcape, which contracts or unfolds according to the depth of the water, ſo that the flower when it opens is always at the ſurface; and when flowering time is paſt, the ſcape contracts and the fructification is completed at the bottom of the water.

The œconomy of this ſingular plant is a remarkable confirmation of Linneus's doctrine of the ſexes in vegetables. Micheli, who did not admit this doctrine, and conſidered the male plant not only as a diſtinct ſpecies but as a different genus from the female, remarks that it is wonderful in theſe flowers, and a ſingular inſtance, that before they open, they are ſeparated from the plant, and being raiſed to the ſurface, open ſuddenly with a kind of elaſtic force, and the ſegments of the petals are bent downwards; in this ſtate they ſwim at large upon the ſurface, and during ſummer and autumn are in ſuch quantities in ſome places as to whiten the whole ſurface of the water.

With reſpect to the female plant, Micheli, who firſt obſerved, deſcribed and figured both, ſays that

Digitized by Google

it is in ſuch quantities in the great ditches about Piſa, that the roots in ſome parts occupy the whole bottom, and the leaves cover the ſurface in ſuch a manner as to impede the paſſage of the barges along them.

Linneus found it abundant in the rivulets of Finmarck, but did not obſerve it to flower either there or at Upſal. Gunner alſo ſays it is every where in Finmarck and Nordland. La Chenal found it in Switzerland, but it is not ſaid where. It grows in the Rhone near Orange [y].

2. Root annual, fibrous. Leaves radical, linear, tapering to a fine point, ſmooth, from nine to twelve inches long, and half an inch or leſs broad—In the Male, peduncle or rather ſcape axillary, ſtraight, a little compreſſed, length of the leaves or more, ſo as to raiſe the flowers above the ſurface of the water. Spathe one-leafed, ſubcylindric, ſomewhat diaphanous, open at the top for the unexpanded flowers to paſs through. Flowers numerous in ſucceſſion, white, pretty large, pedicelled. The pedicels lengthen, when the flowers are ready to expand, ſo as to elevate them juſt above the mouth of the ſpathe. Perianth three-leaved; leaflets lanceolate. Corolla three-petalled: petals linear, recurved, more than twice the length of the calyx. Filaments eight, of unequal lengths, erect, ſhorter than the petals: anthers linear. Germ abortive, three-ſided: ſtyles three.—Female flower: ſcape ſhorter and thicker. Spathe as in the male, one-flowered. Flowers white, elevated above the germ, and above the mouth of the ſpathe, by a very long receptacle, ſtyle or pedicel, which makes up for the ſhortneſs of the ſcape, and brings the flower nearly up to the top of the leaves. Perianth three-parted. Corolla as in the male, only the petals are filiform. Germ cylindric, obſoletely three-ſided, ſeſſile in the bottom of the ſpathe, ending in the above-mentioned flower-elevating receptacle. Style three-cleft to near the baſe: diviſions filiform, white.

Native of the Eaſt Indies, in ſtagnant ſhallow ſweet water [z].

The œconomy of this ſpecies is not ſo curious as in the European; but the end of impregnation is anſwered equally well.

DESCRIPTIONS, *&c.*

1. Stem herbaceous, four-cornered, brachiate. Leaves ovate, ſeſſile, crenate, bluntiſh. Flowers axillary, oppoſite, ſolitary. Habit of Veronica ſerpyllifolia [a].

Stem filiform, pubeſcent. Leaves on ſhort petioles, oppoſite, ſcarcely half an inch long, ſmooth above, the younger ones have a few hairs underneath, ſerrate, veinleſs. Peduncles one-flowered, alternate, ſhort [b].

Native of the iſlands of Montſerrat and Santa Cruz.

2. Root annual. Stem herbaceous, erect, four-cornered with the corners acute, brachiate. Branches of the ſame ſtructure. Leaves oppoſite, half an inch long, hoary-green, a little bent back at the edge, the lower ones crenate, the upper ones often quite entire. Petioles very ſhort. Flowers axillary, ſeſſile, ſmall. Bractes three at the baſe of the calyx, ſeſſile, perſiſtent: two lateral, roundiſh, more produced on one ſide, nearly erect, equal, concave on the lower ſurface; the third ſuperior, twice as large as the others, flat, preſſed to the corolla. Calyx deeply four-cleft: ſegments linear, acute, ciliate, two oppoſite to the larger bracte, wider than the others. Upper lip of the corolla depreſſed to the palate, then aſcending and gaping, emarginate, crenulate, veined: lower lip larger, trifid, the middle ſegment narrower; palate convex, cloſing the throat. Stamens within the throat of the corolla, two outer very ſmall, two inner bigger, ending in two pellucid cohering bodies reſembling anthers, with which they form a bow. Anthers two, oval, adhering below to the bodies juſt mentioned, and one-celled. Germ ovate. Style a little ſhorter than the ſtamens, permanent. Stigma ſemiorbicular, aſcending obliquely towards the anthers. Capſule ovate, two-valved, opening from the top to the baſe, each externally ſemibifid. Seeds very ſmall, ſubglobular; faſtened to a proper receptacle, which is of a quadrangular-pyramidal form. Found in America from the iſland of Trinidad to Braſil; very frequent by way ſides [c].

DESCRIPTION, *&c.*

A tree with round ſmooth branches. Leaves petioled, oppoſite, ovate, attenuated to both ends, ſmooth, quite entire. Stipules interpetiolary, connate, acuminate. Peduncles axillary, three or four times dichotomouſly branched. Flowers pedicelled. Fruit eſculent [d]. Willdenow remarks, that it reſembles Callicarpa in habit. In the ſyſtem it comes after Chiococca. According to Juſſieu, it is a ſmall tree, with the flowers corymb-cymed and axillary. He takes his character from Commerſon's deſcription and figure.

Suppoſed to be a native of China. Cultivated in the botanic garden at Santa Cruz. More probably from Madagaſcar.

   Leaves lanceolate, ſpikes oblong.
7. Varronia anguſtifolia. *Narrow-leaved Varronia.*
   Lin. ſpec. ed. Willd. 1. 1081. *Weſt St. Cruc.* 202.
   Leaves linear rugged ſomewhat toothed, ſpikes linear-oblong.
8. Varronia alba. *White-fruited Varronia.*
   Lin. ſpec. 276. *ſyſt.* 231. *Reich.* 1. 534. *Willd.* 1. 1081. *Jacqu. amer.* 41. *pict.* 26. *Comm. hort.* 1. 155. *t.* 80. (Meſpilus.)
   Leaves cordate, flowers cymed.
9. Varronia monoſperma. *One-ſeeded Varronia.*
   Lin. ſpec. ed. Willd. 1. 1081. *Jacqu. hort. Schoenbr.* 1. 18. *t.* 39.
   Leaves ovate rugged quite entire at the baſe, ſpikes cymed.

DESCRIPTIONS, &c.

1. Leaves lanceolate, attenuated to both ends. Peduncles lateral, elongated, filiform, faſtened to the petiole at the baſe [o].

[o] Linn. ſpec.

It is a ſhrub four feet in height, and branched ſo like the fifth ſort, that it ſeems as if it were a variety of it growing on rocks. But according to Browne the nuts are two-celled. In this the fruit has two ſeeds [f].

Browne ſays, it ſeldom riſes above three or four feet in height, and is furniſhed with a number of ſlender, crooked, intermixed branches.

Native of the Weſt Indies. Common in the lower woody lands of Jamaica [g].

2. This is a ſhrub a fathom in height, warted; with round rough-haired branches. Leaves petioled alternate, ſcattered, acuminate, doubly ſerrate, rugged. Flowers cluſtered in little roundiſh balls. Pedúncles terminating and axillary, ſhorter than the leaves, rugged. Corollas ſmall, white. Calyx bell-ſhaped. Corolla larger than the calyx; the five parts are obtuſe, crenate, erect. Anthers whitiſh, bifid at the baſe. Germ ſuperior. Drupe ſcarlet, one-ſeeded. The reſt as in the character. Native of Jamaica, in dry coppices near the ſea: flowering in ſpring [h].

3. Stem from two to three feet high, fruteſcent, branched, erect; rough-haired. Branches nearly upright, ſtiff, hairy with the hairs preſſed cloſe. Leaves petioled acuminate, wider at the baſe, nerved, rough-haired. Racemes terminating, ſhort, often ſubdivided, compoſed of many ſeſſile flowers, all directed one way. Calyx half-five-cleft: ſegments acuminate, erect. Corolla ſalver-ſhaped: tube three or four times as long as the calyx, round, erect; border wheel-ſhaped, five-rayed, five-cornered. Filaments inſerted into the tube near the border, very ſhort. Anthers above the throat, marked with lines, blue. Germ oblong. Style length of the tube, four-cleft at the tip, permanent. Stigmas ſimple, yellow. Drupe roundiſh, ſmall, ſurrounded at the baſe by the calyx, red. Nut roundiſh, with a ſingle kernel. Native of St. Domingo, where the French call it *Dent de Chien blanc.* It flowers there in december and january [i].

Jacquin ſays it is the moſt elegant ſhrub of the genus, and often attains the height of twelve feet; that the leaves are two inches long; that the common peduncles terminate in roundiſh ſpiked heads, ſimple or compound; that the flowers in ſize and form reſemble thoſe of Marvel of Peru, (whence the trivial name;) that they are white, handſome, but void of ſmell; that the ſegments of the calyx end in long briſtles; and that the drupe is red, the ſize of a pea, filled with ſweet glutinous pulp.

4. This ſhrub is the height of a man; the leaves three inches long. The ſpikes are an inch or two in length [k]. Swartz ſays, it is certainly not different from the curaſſavica, (n. 6.) which often varies with narrower and wider leaves, more or leſs pubeſcent; and with larger or ſmaller ſpikes [l].

Native of Martinico, on the borders of woods.

5. This ſhrub agrees with the preceding: but differs in having the ſpikes conſtantly globular, the ſegments of the corollas emarginate, and the ſtigma blunt and four-fold [m].—Linneus remarks, that there is a naked peduncle from the forks; and that the teeth of the calyx are linear, long, and recurved.

According to Swartz, it ſeems to be a variety of *V. bullata*, under which name there is a ſpecimen of *V. globoſa* in Linneus's herbarium [n].

Native of the Weſt Indies, on the coaſt.

6. Stem ſhrubby, a fathom in height, upright; branches and branchlets, rugged, ferruginous. Leaves petioled, ovate-lanceolate, rounded at the baſe, having a blunt point at the end, ſubſerrate, nerved, wrinkled, rugged above, tomentoſe beneath. Spikes terminating, upright, an inch long. Peduncle ſhort, (on the branchlets,) thick. Flowers cluſtered, ſeſſile, biggiſh, white. Calyx inferior, bell-ſhaped, ſomewhat ventricoſe, ſlightly five-cornered. Corolla longer than the calyx. Filaments from the middle of the tube, hirſute at the baſe: anthers ovate. Style longer than the corolla, cloven to the middle, and the two ſegments cloven, thickiſh at the tip. Drupe roundiſh, placed on the calyx, and half covered by it, ſcarlet, one-ſeeded [o].

[f] Jacquin. [g] Browne. [h] Swartz obſ. [i] Swartz deſcr. [k] Jacquin. [l] Obſ. 89. [m] Jacquin. [n] Obſ. 88. [o] Swartz obſ.

I Accord-

Digitized by Google

According to Jacquin, it attains fifteen feet in height. The ſpikes are cloſe, two or three inches long, on a peduncle of two inches. Flowers ſmall, void of ſcent. The ſubovate ſegments of the inflated calyx end in briſtle-ſhaped teeth of the ſame length with themſelves. Tube of the corolla as long as the calyx: border ſhort and emarginate. Filaments a little ſhorter than the corolla. Style alſo ſhort, with a headed ſimple ſtigma. Drupe ſmall, red [p].

Common in the lower woody lands of Jamaica, where it is generally found climbing or leaning on the neighbouring ſhrubs [q]: flowering in ſummer and autumn. It grows alſo in Curaçao.—Introduced about 1778, by John Hope, M. D. [r]

7. Leaves lanceolate-linear, blunt, rolled back at the edge, rugged above, tomentoſe beneath. Native of the iſland of Santa Cruz [s].

8. This is a tree, often thirty feet in height, with a large head, and a trunk half a foot in diameter; but when planted in hedges becomes ſhrubby. Leaves ovate or roundiſh-ovate, ſubcordate at the baſe, four or five inches long. Cymes ample, not unfrequently half a foot in diameter, having numerous whitiſh flowers, without ſcent. Calyx at firſt entire, but when the corolla expands, ſeparating horizontally into an upper valve which withers, and into a lower which is permanent, and has the margin very ſlightly five-toothed. Border of the corolla bell-ſhaped. Styles bifid, and the ſegments bifid terminated by obtuſe ſtigmas. Drupe ſomewhat oblong, half an inch in length, whitiſh, ſubpellucid: pulp whitiſh, ſweet, inſipid, glutinous. Nut oblong, ſtriated, black. Native of Carthagena and Curaçao, where the nut is eaten [t].

9. Leaves ovate or ovate-lanceolate. Spikes roundiſh. Nut one celled. Native of the Caracas [u].

Loureiro has a ſpecies, which he names V. ſinenſis. He deſcribes it as a middle-ſized tree with ſpreading branches: the leaves ovate-lanceolate, quite entire, ſhining, oppoſite and alternate, ſubpetioled. Flowers white, on many-flowered peduncles, lateral and terminating. Calyx ſubcampanulate, ſhort. Corolla campanulate, with a ſhort thick tube, and the ſegments of the border ovate, ſpreading, equal. Filaments inſerted into the mouth of the tube, nearly equal to the corolla. Drupe ſmall, ſmooth, red, acid, eatable. Nut four-celled. Native of China. The pulp of the fruit is in frequent uſe among the Chineſe, as aſtringent, exſiccating, and cephalic.

VASCULIFERA. See *Nigrina*.

Lin. ſyſt. 443. *Reich.* 2. 416. *Willd.* 2. 847. *mant.* 242. *Smith ic. ined.* 2. *t.* 36.

DESCRIPTION, *&c.*

This is a tree having the ſame appearance with Vateria indica, and nearly allied to it, but differing in the anthers and perhaps in the fruit. Branchlets indiſtinctly angular, hoary with meal, leafy, many-flowered. Leaves alternate, ovate-oblong, bluntly acuminate, quite entire, ſmooth, with the veins ſtanding out on both ſides and alternate, and the veinlets netted and anaſtomoſing. Petioles an inch long, angular, ſtriated, hoary, below the point of junction with the leaf a little thickened and much wrinkled. Stipules none. Panicles axillary, ſeſſile, compound, many-flowered. Bractes none. Peduncles alternate, branched, angular, hoary with meal, as are the calyx and corolla before they unfold. Pedicels ſhort, thickened at the top, erect, one-flowered. Segments of the calyx ovate-lanceolate, acute, erect, only one third of the length of the corolla. Petals obovate, ſmooth within, half-hoary without, in ſome flowers, incumbent towards the left, in others towards the right, which is very ſingular. Anthers three, ſeſſile on the claw of each petal, ſmall, ovate, ſmooth. Germ ſuperior, blunt, hoary. Style five-cornered, contorted. Stigma ſubtrilobate.

Native of China. A very rare plant, and as yet very obſcurely known [x].

VELAGA. See *Lagerſtroemia*.

VELEZIA. (*So named by Linneus, from Chriſtoval Velezius, examiner, firſt phyſician, and demonſtrator of botany, in the College of Apothecaries at Madrid. Loefling ſaw there his Flora of the plants about Madrid in manuſcript.*)

Paronychia orientalis humifuſa, Serpylli folio. *Tournef. cor.* 38.

DESCRIPTION, *&c.*

Root annual. Stem very much branched. Calyxes ſeſſile, cylindric, very narrow. Border of the petals very ſmall, marked at the baſe with a purple creſcent, as in the natural order of Caryophyllæi, to which this belongs [y].

Stem upright, jointed, round, pubeſcent, three or four inches high. Branches ſlender, often divaricating. Leaves oppoſite, awl-ſhaped, ſtriated, pubeſcent, ſheathing at the baſe. Flowers axillary, ſolitary, or ſometimes but ſeldom two or three together, along the ſtem and branches, on ſhort pedicels. Calyx ſlender, pubeſcent, cylindric, very ſlightly ſtriated; the teeth briſtle-ſhaped, erect. Corolla ſmall, a little longer than the calyx; border roſe-coloured, ſlightly emarginate. Stamens five or ſix, ſometimes ſeven, the length of the petals [z].

Capſule very long, clothed with the permanent calyx, opening into four parts at the top. Receptacle briſtle-ſhaped, central, free, almoſt the length of the capſule, covered with the ſubalternate ſeeds, incumbent downwards. Seeds as many as twelve, ſmall oblong, produced at top into a ſhort point, convex on one ſide, on the other concave from the margins bent back into a belly, and gaping with a wide longitudinal cleft, in other parts even, blackiſh or dark brown, inverted. —It differs from Dianthus chiefly in the definite ſituation of the ſeeds, the leſs number of ſtamens, and the abſence of ſcales at the baſe of the calyx [a].

Native of the South of Europe; and of Barbary, near Maſcar. Cherler firſt obſerved it in the ſouth of France, and Ray found it near Florence.

It was introduced in 1785, by Caſimir Gomez Ortega, M.D. and flowers in july [b].]

Leaves entire obovate ciliate, ſilicles erect.

DESCRIPTIONS, *&c.*

[1. Root annual, ſmall, fibrous. Cotyledons obcordate, ſmooth. Stem branched, leafy, hiſpid with briſtles bent down. Leaves alternate; bipinnatifid; ſomewhat hiſpid. Spikes terminating, many-flowered. Flowers pedicelled. Calyx tubular, cloſed with the leaflets converging longitudinally, ſhining, purple. Petals obovate, entire, whitiſh or very pale yellow with deep purple veins, and very ſlender claws. Silicle bent down, elliptic, hiſpid, with the partition ſtanding out, ſmooth, ſpreading. Seeds on each ſide three or four, roundiſh [c].

Gærtner deſcribes the Silicle as ſubglobular, hard, hiſpid with ſoft briſtles, two-celled, two-valved: valves cruſtaceous, with three raiſed ſtreaks on the outſide, from which the briſtles ſpring; within poliſhed and ſhining: partition parallel to the valves, very thin and diaphanous within the ſilicle, on the outſide of it, produced into an ovate opaque coriaceous ſcrew-ſhaped lamina. Seeds three or four in each cell, ſubglobular, angular, of a dark ferruginous colour and mucilaginous.

Firſt obſerved in the kingdom of Valentia in Spain, by Cluſius. Mr. Lawſon found it on Saliſbury plain, not far from Stonehenge [d]. It flowers in june.

2. Stems ſhrubby, two feet high, ſomewhat rugged, very much branched. Leaves alternate, rugged, thickiſh, with two ſhorter leaves frequently coming out at the axils, ſo that the leaves appear to be ternate, as in Cytiſus ſeſſilifolius. Flowers in ſpikes terminating the ſtem and branches. Calyx-leaves cloſely converging. Petals yellow, orbicular, variegated with paler veins; claws filiform, ſlightly channelled within, a little longer than the calyx. Anthers yellow, oblong, all fertile; the longer pair of filaments connate at bottom, the ſhorter free or diſtinct. Between the germ and the ſhorter filaments a harder gland. Silicle erect, obovate, gibbous on one ſide at the baſe; valves hard; ſtriated longitudinally; partition parallel to the valves, and twice as long as they are, erect, ovate, compreſſed beyond the ſilicle. Seeds ovate, one in each cell, and one of them frequently abortive. Near Aranjuez in Spain [e]: where it was firſt obſerved by Minuart [f], and after by Cavanilles. It flowers and fruits there in may.

Cavanilles denies that the connate pair of filaments is caſtrated.

Mr. Miller cultivated it in 1759: and it flowers here in april and may [g].]

PROPAGATION AND CULTURE.

1. If the ſeeds be permitted to ſcatter, the plants will come up and thrive very well: or if they be ſown in autumn, they will ſucceed much better than when ſown in the ſpring, for theſe will frequently lie in the ground till the autumn; whereas thoſe which are ſown in autumn come up ſoon after, or early in the ſpring, and will more certainly produce ripe ſeeds. Theſe plants ſhould not be tranſplanted; the ſeeds therefore

[c] Smith. [d] Ray. [e] Cavanilles. [f] Linn. ſpec. [g] Hort. kew.

Digitized by Google

ſhould be ſown where they are to remain, and require only to be kept clean and thinned.

2. This is increaſed by ſeeds like the former; and will continue two or three years.

DESCRIPTION, *&c.*

This is a large climbing ſhrub. Leaves alternate, on ſhort petioles, two-faced, ovate, moſt ſlightly ſerrate, ſmooth, three or four inches long. Panicle terminating. Flowers very numerous, ſmall, of a dirty greeniſh colour, ſmelling very ſtrong and offenſive, not unlike that of Sterculia fœtida. Calyx, corolla, nectary, ſtamens and piſtil as in Rhamnus Jujuba. Capſule the ſize of a pea[h]: ſmooth, fibroſe-coriaceous. Seed of a red ruſty colour[i]. This ſhrub is generally dioecious; and is a native of foreſts and other uncultivated places among the mountains in the Eaſt Indies; flowering during the cold ſeaſon.

The natives of the mountains apply the bark in a green ſtate to many uſeful purpoſes as cordage[k].

DESCRIPTIONS, *&c.*

1. Root perennial, compoſed of many thick fibres gathered into a head. Leaves oblong-ovate, ten inches long, and five broad in the middle, rounded at the end, and having many longitudinal plaits like thoſe of Gentian. Stems three or four feet high, branching out on every ſide almoſt their whole length: under each of theſe branches is placed a narrow plaited leaf, and theſe diminiſh in ſize as they are near the top of the ſtem. The branches and principal ſtem are terminated by ſpikes of flowers ſet very cloſe together, of a greeniſh white or herbaceous colour. They appear in july.

[The three capſules are ſuperior, united at the baſe, but diſtinct above, end in a ſhort filiform ſtyle, and open by the inner ſuture. Seeds ten or twelve, ovate-oblong, narrower upwards, bracted, ſurrounded by a wide membranaceous margin, ſomewhat concave, variouſly wrinkled, of a bay colour: they are faſtened in a double and in an erect poſition to the edges of the opening ſuture[l].

Native of Greece, Italy, Switzerland, Auſtria, the ſouth of France and Ruſſia.—Cultivated by Gerarde in 1596[m].

It appears that not only the roots of White Hellebore, but that every part of the plant is extremely acrid and poiſonous. The leaves and ſeeds have proved deleterious to different animals.

Veratrum has been given internally in mania, epilepſy, &c. notwithſtanding its virulence; but the diſeaſes in which its efficacy ſeems leaſt equivocal, are thoſe of the ſkin, as ſcabies and different prurient eruptions, herpes, morbus pediculoſus, lepra, ſcro-

[l] Gærtner. [m] Hort. kew.

phula

phula, &c. in many of theſe it has been ſucceſsfully employed both internally and externally.

As a powerful ſtimulant, and irritating medicine, its uſe has been reſorted to only in deſperate caſes; and then it is firſt to be tried in very ſmall doſes, in a diluted ſtate, and to be gradually increaſed, according to the effects. Greding, who employed it in a great number of maniacal caſes, gave the bark of the root collected in ſpring, in powder, beginning with one grain, and gradually increaſing the doſe. He alſo ſometimes uſed the extract, prepared after Stoerck's manner [n].

2. Native of North America. Cultivated in 1763. by Peter Collinſon, Eſq. It flowers in july and auguſt [o].]

3. This has a perennial root like the firſt ſort. The leaves are longer and thinner; they are plaited in like manner, but are of a yellowiſh green colour, and appear ſooner in the ſpring; the ſtalks alſo riſe higher. It has fewer leaves, and does not branch out into ſo many ſpikes. The flowers are of a dark red colour, with the petals ſpread open flat; and they appear almoſt a month ſooner than thoſe of album.

[It is very nearly allied to the firſt, but differs in place of growth, colour, villoſe peduncles, ſpreading corolla, and compound raceme not ſubdivided into a panicle [p].]

This ſpecies ſeems not to be ſo ſtrong and acrid as the firſt; for when both ſorts are placed near each other, ſnails will entirely devour the leaves of this, when they will ſcarcely touch thoſe of the other.

[Native of Auſtria and Siberia. Cultivated in 1596, by Gerarde [q].]

4. Root tuberous and large. Leaves oblong, ſhaped like thoſe of Plantain, having ſeveral longitudinal furrows, or plaits; they are four or five inches long, and two broad in the middle, and ſpread themſelves on the ground. Between theſe comes out a ſingle ſtem, near a foot high, having a very few ſmall leaves or ſheaths placed on it alternately. The flowers are produced at the top, in a ſingle thick cloſe ſpike; they are ſmall, and of a yellowiſh white colour. They appear in june, but are rarely ſucceeded by ſeeds here.

[Root bulbous. Radical leaves many, broad-lanceolate, nerved, firm, ſmooth. Stem a foot high, quite ſimple. Stem-leaves few, placed unequally, narrow, lanceolate, ſeſſile but not ſheathing as in the others, ſmall. Raceme at firſt ovate, then the length of the ſtem, denſe, compoſed of ſmall yellow flowers [r].

Native of North America. Cultivated by Mr. Miller in 1759 [s].]

PROPAGATION AND CULTURE.

Sow the ſeeds as ſoon as ripe, either in a bed or box filled with freſh light earth, and keep the ground conſtantly clean from weeds. In the ſpring the plants will appear; if the ſeaſon then prove dry, refreſh them now and then with water, and carefully clear them from weeds. The autumn following, when their leaves decay, prepare a bed of freſh light earth, take up the young plants carefully, without breaking their roots, and plant them about ſix inches ſquare; let them remain until they are ſtrong enough to flower, when they ſhould be tranſplanted into the borders of the pleaſure-garden: but as theſe plants ſeldom flower in leſs than four years from ſeeds, this method of propagating them is not much practiſed in England.

When theſe plants are once obtained, they may be increaſed by parting their roots in autumn, when their leaves decay; but they ſhould not be parted too ſmall, for that will prevent their flowering in the following ſummer. Plant them in a light, freſh, rich ſoil; and do not remove them oftener than once in three or four years. They are pretty ornaments, when planted in the middle of open borders of the pleaſure-garden: if they be planted near fences which harbour ſnails, they will eat the leaves, eſpecially of the third ſort, and deface the plants very much.

Leaves woolly radical, ſcape naked.

DESCRIPTIONS, *&c.*

1. [Root biennial, ſpindle-ſhaped. Stem erect, ſimple, ſtiff, and ſtraight, from three to five feet high, leafy, woolly, angular, winged. Leaves alternate, decurrent, oblong, nearly entire, very thickly clothed on both ſides with white branched intricate villoſe hairs. Spike terminating, erect, cylindrical, many-flowered. Flowers ſeſſile, cloſely ſet, bright yellow, ſometimes but rarely white. Filaments yellow, hairy: anthers red. Stigma club-ſhaped [t].

Leers remarks, that the two lower filaments are longer than the others, and naked; the three upper white-villoſe.

Native of Europe and Siberia, on banks in hedges and on waſte ground, eſpecially on a gravelly or calcareous ſoil, flowering in july and auguſt.

The leaves and whole herb are mucilaginous, and recommended as emollients both internally and externally. A pint of Cow's milk with a handful of the leaves either of this or the pulverulentum, boiled in it to half a pint, ſweetened with ſugar, ſtrained and taken at bed-time, is a pleaſant emollient and nutritious medicine for allaying a cough, and more particularly for taking off the pain and irritation of the piles. It is often applied externally in this diſorder: and is uſed as an injection in teneſmus with advantage. In diarrhœas of an old ſtanding a decoction of it is uſeful to eaſe the pains of the inteſtines: two ounces of the leaves are boiled in a quart of water, and four ounces are given every three hours. In pulmonary complaints of cattle it is found to be of great uſe, and hence its name of Cow's Lung-wort. It is well known to the country cow-leeches under the name of Murrain-graſs, which is a corruption of Mullein. The French call it Bouillon blanc, and uſe an infuſion of the flowers in coughs, ſuppoſing them to poſſeſs anodyne and pectoral virtues. It does not ſeem to have much of the narcotic powers for which moſt of its natural order are diſtinguiſhed. The ſeeds, however, are ſaid to ſtupify fiſh ſo much that they may be taken with the hand [u].

In the Eaſt Indies the natives have a ſuperſtitious notion of the efficacy of this plant in protecting them from the viſitation of evil ſpirits.

It has many names in Engliſh. Gerarde enumerates Mullein or rather Woolen, Hig-taper, Torches, long Woort and Bullockes Longwoort and Hares bearde. Dr. Withering adds, Ladies Foxglove. It is probable that Gerarde's correction of Mullein to Woollen is right, eſpecially ſince it is called in Dutch Wullkraut. Is the French *Molene* borrowed from our Mullein? Hig-taper is altered to High Taper in all modern books, ſuppoſing it to be ſo named from its high tapering ſtem: but in the north it is Hag-taper. Might not this be from its ſuppoſed efficacy in ſorcery?

The Verbaſcums ſeem apt to produce varieties, eſpecially mules. Mr. Robſon communicated to Dr. Withering a hybrid or mule plant, produced under his own eye, from this ſpecies impregnated by the nigrum, in 1790. Hence he calls it Thapſo-nigrum. It flowered five years ſucceſſively, but produced no perfect ſeed. It is difficult to ſay to which of its parents it is moſt nearly allied. In V. Thapſus the leaves are decurrent; in nigrum they are petioled: in this mule the lower leaves are petioled, and the upper decurrent. V. Thapſus has three of its ſtamens hairy, and two ſmooth; nigrum has all the ſtamens hairy: the mule has all its ſtamens hairy, but two of them only on one ſide [x].

Murray (prodr. 47.) mentions a variety of this under the name of Verbaſcum bicolle, or n. 582 of Haller, which he deſcribes as having the lower leaves petioled, and the upper ſeſſile and decurrent, as in the other mule. The ſtigma is ſhortly two-necked [y].

2. This is ſuppoſed by Linneus to be a mule plant, produced from V. Lychnitis as the mother, and V. Thapſus as the father. It appeared in the botanic garden at Upſal in 1761, in the ſame bed with its parents, and was barren. It agrees with the mother in its branched ſtem, flowers, and purple hairineſs of the filaments, though leſs ſo than in V. Lychnitis. It agrees with the father in ſize, in the leaves being decurrent but not totally, and leſs white than in V. Thapſus, and in the calyxes, which are however more peduncled, though leſs ſo than in V. Lychnitis; of which it is rather a variety than a diſtinct ſpecies. The younger Linneus obſerved it. But it was long ſince remarked by Agerius, who ſent it to John Bauhin, and from him ſubſequent authors have taken it [z]. Willdenow conſiders it as a diſtinct ſpecies. See Verbaſcum Lychnitis.

3. Root annual. Leaves ſeſſile but not decurrent, ſpatulate, narrower at the baſe, ſinuate but ſcarcely lyrate, almoſt naked above, ſomewhat tomentoſe beneath. Spike like that of the firſt ſpecies, with the flowers ſeſſile, not crowded very much together, but ſeveral to each bracte and bigger. Corollas yellow, with the ſtamens and piſtils purple [a].]

Lower leaves ovate, about a foot long, and ſix inches broad in the middle, ending in round blunt points, on thick footſtalks, their upper ſide green, but their under ſide downy and of a hoary-white colour, with ſome ſtrong longitudinal veins. Stem from three to four feet high. Stem-leaves oblong, of the ſame texture with thoſe below, but ſeſſile, longer, and ending in points. Flowers in a looſe terminating ſpike, with one very narrow leaf under each. Corolla of a brimſtone colour and larger than thoſe of the common Mullein. The flowers have an agreeable ſcent at a little diſtance; but if ſmelt to long, or too near, it becomes leſs pleaſant. They appear in june and july, and the ſeeds ripen in the autumn, when the plant decays, being biennial. The ſeeds were given to Mr. Miller by Boerhaave, who informed him that he had received them from Vienna [b].

[Native of the South of Europe. Cultivated in 1758 by Mr. Miller.

4. Native of the iſland of Madeira; where it was found by Mr. Francis Maſſon, and introduced in 1777. It flowers from june to auguſt, and is biennial [c].

5. Root biennial. Stem erect, ſpiked, very tomentoſe. Leaves ovate, not at all cordate, crenate; the lower ones on a petiole which is flat above; the upper ones ſeſſile, half embracing but not decurrent. Raceme ſpike-ſhaped, with ſcattered lanceolate bractes; within each of which are four flowers, the middle ones blowing firſt, then the loweſt, and laſtly the two lateral ones. Capſules oblong. Native of Italy [d], Germany, and the ſouth of France.—Cultivated in 1739 by Mr. Miller. It flowers in june and july [e].

6. Root biennial. Stem erect, ſeldom more than three feet high, ſtiff and ſtraight, angular, woolly, leafy, terminating in a panicle very much branched. Leaves elliptic-oblong, ſomewhat wedge-ſhaped, crenate, cloſely woolly beneath, but nearly ſmooth on the upper ſide, netted-veined; the radical ones attenuated at the baſe; the ſtem-leaves ovate, ſeſſile but not decurrent. Branches of the panicle racemed, many-flowered. Flowers pedicelled, in bundles, cream-coloured with yellow filaments and ſaffron-coloured anthers [f].

This ſpecies is remarkable for its ſtraight wand-like angular,

[t] Smith. [u] Woodville, Engl. bot. Withering.

Digitized by Google

angular ſtem; its leaves very white beneath, but green with a ſlight hoarineſs above, and its cream-coloured flowers, which are produced in great numbers in a compound cluſtered terminating raceme.

Our Engliſh ſpecimens of White Mullein agree preciſely with that in the herbarium of Linneus, which we learn, from certain marks and numbers, to be what he intended in the firſt edition of Species Plantarum for Verb. Lychnitis; though even in that work he ſeems to reckon our hoary yellow Mullein as the original ſpecies, making the white a variety [z].

Native of Europe. With us found chiefly in Kent, and there plentifully. In lanes about Dartford very common. Dr. Stokes found it at Kinver in Staffordſhire, near the Rock Houſes.

Dr. Smith conſiders V. Thapſoides as a variety of this ſpecies, and adopts it on the authority of Linneus, and Hudſon who ſays it grows in Kent.

The album of Miller cannot be this ſpecies. He ſays it grows naturally in Italy and Spain, and is ſix or ſeven feet high.

7. Root biennial. The whole herb is covered with a mealy down which eaſily rubs off, and when ſeen in a microſcope is found to conſiſt of numerous ſtarry entangled tufts. Stem upright, three or four feet high, round, leafy, terminating in a pyramidal branched panicle, compoſed of many flowers. All the leaves ſeſſile, mealy on both ſides, ſlightly ſerrate or crenate: root-leaves elliptic-oblong, often above a foot in length; ſtem-leaves ovate, acuminate, almoſt embracing. It has the inflorescence of the preceding ſpecies, only more branched. The corolla is larger, and of a bright yellow. The filaments are bearded with pale or white hairs; and the anthers are vermilion [a].

Native of Europe. Common in many parts of Norfolk and Suffolk, as about Norwich and Bury; in waſte ground, hedges and the borders of fields: flowering in july, at which time it forms a golden pyramid a yard high, of many hundreds of flowers, and is one of the moſt magnificent of Britiſh herbaceous plants. Ray found it at Wollerton near Nottingham.

A ſingular inſtance of irritability in this and ſome other ſpecies of Verbaſcum has been pointed out by Mr. Correa. In ſtill warm weather, if two or three ſmart blows be given to the ſtem with a ſtick, all the corollas which are then open, though not immediatly looſened, fall off in a few minutes, ſeparating one after another from their baſe, and the calyx cloſes round the germ, ſeeming as it were to puſh the bloſſom off.

Dr. Smith has obſerved a mule plant produced from this ſpecies impregnated with the pollen of Verb. nigrum; having the habit of the former, and purple-haired filaments like the latter; with the leaves more neatly crenate than in this ſpecies, the root-leaves petioled, the ſtem and petioles purple. It is frequent at Helleſdon near Norwich [t].]

8. Root perennial. Bottom leaves ovate-oblong, indiſtinctly crenate, (doubly crenate, *Ait. kew.*) dark green above, pale green beneath, ſtanding upon pretty long footſtalks. The ſtalk riſes three or four feet high, branching out on each ſide, and has a few ſharp-pointed ſmall leaves on the lower part, ſitting cloſe to the ſtalk. The flowers are diſpoſed in a long looſe ſpike on the upper part of the ſtalk; they come out upon ſhort ſlender pedicels, three or four from the lower joints; above theſe there are two at each joint, and at the top they are ſingle; they are of a ruſty iron colour, and larger than thoſe of the common ſort. They appear in july and auguſt, but do not produce ſeeds here. It is common in gardens, where it is known by the name of Iron-coloured Moth Mullein. [Mr. James Sutherland cultivated it in 1683. It is a native of the South of Europe [k].

9. Root perennial. Stem ſtiff and ſtraight, angular, ſtriated, purpliſh, ſometimes pubeſcent, little branched. Root-leaves cordate, on long petioles; ſtem-leaves cordate-lanceolate, petioled; uppermoſt almoſt ſeſſile; all waved-crenate or ſubſerrate, netted-veined, dark green, naked or ſometimes hoary beneath, eſpecially the upper ones. Spike terminating, for the moſt part ſimple or ſolitary, many-flowered, but not very compact: longer and more ſimple than in moſt of the other ſpecies. Flowers in bundles, (about ſeven in a ſet,) pedicelled [l]. The beauty of its golden-coloured corolla is much enriched by the tints of purpliſh brown at the mouth of the tube, the purple-haired filaments, and the ſaffron-coloured anthers [m].

Native of Europe in a calcareous or gravelly ſoil; flowering about midſummer, and laſting till ſeptember. Plentiful in Kent, and in the hedges of retired graſſy lanes ſo frequent in Norfolk and Suffolk [n]. In the calcareous parts of Cambridgeſhire, and the ſandy parts of Bedfordſhire. Nettlebed, Henley and Stokenchurch in Oxfordſhire. Between Birmingham and Walſall. About Hampſtead, near Richmond bridge, at Strand on the Green, and about Harefield in Middleſex. Crayford, Shooter's hill, Charlton, Blackheath, Lewiſham, Woolwich warren, Bromley, Weſt Wickham, Plumſtead, Bexley, Weſterham, Orpington, Dartford and Oſpringe in Kent. Dupper's hill near Croydon, about Eſher and Godalmin in Surrey. Tillington in Suſſex.

It is pity that Linneus adopted its common name of nigrum or black as a trivial, becauſe it tends to miſlead, for it has nothing black about it, the leaves being only dark-coloured in compariſon with the other ſpecies, Thapſus, Lychnitis and pulverulentum; the nap on all which may be uſed for tinder, or to make wicks for lamps, whence the name of *Lychnitis* to the ſixth ſpecies.

This varies ſometimes with white flowers; and Gmelin mentions a lower variety with a funnel-form herbaceous flower, that is proliferous [o].

10. Root biennial, thick, branched, whitiſh, bitter. Whole plant much larger and ſtronger than Blattaria, clothed generally all over, and the lower leaves conſtantly, with ſhort prominent, often forked, glandular hairs. Stem erect, five or ſix feet high, branched from the bottom, leafy, round, but ſomewhat angular or winged from the leaves running down it. Radical leaves reſembling thoſe of the Primroſe, lanceolate-oblong, wrinkled, unequally tooth-crenate, pinnatifid-gaſhed at the baſe, above ſhining a little and having ſcattered hairs beneath veined and woolly: ſtem-leaves oblong-lanceolate, toothed and gaſhed, ſubſeſſile; the upper ones heart-ſhaped, long-pointed, toothed, ſeſſile, and even in ſome degree embracing. Flowers axillary, in bundles or cluſters, on ſhort woolly ſtalks, and ſome of them ſeſſile, very large, yellow, purple about the centre, ſoon falling off. Filaments yellow, bearded in the middle with purple. Segments of the calyx ovate, larger and broader than in V. Blattaria. The woollineſs of the ſtem and branches varies in degree, and weak plants have ſometimes ſolitary flowers, but always on much ſhorter thicker ſtalks than the Blattaria.

Firſt found by Mr. Waldron Hill of Worceſter in a field on the ſouth ſide of a lane leading from Gregory's mill to the turnpike road from Worceſter to Omberſley, oppoſite to the lane leading to Beverey. It was cultivated for three years without any perceptible alteration, according to Dr. Stokes [p].

In Engliſh Botany it is added, from the information of the Rev. Mr. Baker, that it was firſt obſerved growing plentifully in a field near Wrexham, by Mrs. Naſh, who planted it in her garden near Beverey, whence probably its ſeeds got into the neighbouring turnpike road to Omberſley, and thence into the lane leading to Gregory's mill. This is omitted in Dr. Smith's poſterior publication of his Flora.

Dr. Stokes firſt clearly aſcertained this ſpecies, which in many reſpects is cloſely allied to V. Blattaria, but does not ſeem to be a variety of it, or a mule; for that does not grow where this is found, and it may be copiouſly propagated by ſeed. It flowers in auguſt and ſeptember [q].

11. Root biennial. Radical leaves ovate, ſubſeſſile, naked, even, wrinkled, ſcarcely crenate. Stem erect, ſimple, two feet high. Branches from the loweſt axils,

[z] Engl. bot. [a] Smith brit. [t] Engl. bot. [k] Hort. kew. [l] Smith brit. [m] Withe and engl. bot. [n] Engl. bot. [o] Fl. fib. 4. 91. n. 46. t. 47. Reichard ſyſt. [p] Stokes in With. Smith brit. and engl. bot. [q] Engl. bot.

erect,

Digitized by Google

erect, ſimple, length of the ſtem, all angular, ſubpubeſcent with hairs clammy at the tip. Stem leaves cordate, ſeſſile, ſmooth, wrinkled and veined. Raceme of all terminating, ſimple, a foot long. Peduncles ſimple, ſolitary, one-flowered. Lower leaflets of the calyx commonly ſmaller than the others. Corolla deep purple. Filaments purple, bearded; in the three upper ones the beard is white. Anthers kidney form, compreſſed, blackiſh, with fulvous pollen. Piſtil purple, bent down [r]. Capſule ovate-acuminate, with a longitudinal ſtreak on each ſide, of a ſtiff coriaceous ſubſtance, the valves when ripe cloven to the middle: partition doubled, formed from the edges of the valves bent in. Receptacle ovate-globular, ſpungy, placed in the axis of the fruit, deciduous when ripe. Seeds many, ovate-globular, ſomewhat angular, excavated, brown [s].

Native of the South of Europe, and of Germany. Cultivated in 1597, by Gerarde. It flowers from may to july [t].

12. Root annual fuſiform. Stem about three feet high, erect, branched, leafy, angular, ſmooth. Leaves obovate-oblong, doubly-ſerrate, ſmooth, embracing: root-leaves ſublyrate. Racemes terminating, glandular-hairy, ſtiff, many-flowered. Flowers peduncled, ſolitary, yellow ſtreaked more or leſs with purple, having each a ſingle ovate bracte at the baſe of the peduncle. Stamens clothed with purple hairs [u]. Germ globoſe. Capſule rather oblong. The upper part of the ſtem, as well as the germ, calyx, bractes, and upper leaves, clothed with ſhort hairs tipped with a minute globe [x].

Native of the South of Europe, Germany, Switzerland and England, in clayey and gravelly ſoils. In Devonſhire, Dorſetſhire and Cornwall not uncommon, as about Plymouth and Aſhburton. Near Rocheſter, by the river Medway. Between Deptford and Greenwich. In a lane between Mitcham common and Carſhalton. In gardens it is frequently cultivated, and is very ornamental; flowering from july to november, or even later, if the weather be mild.

The Hon. Mrs. F. Howard gathered a ſpecimen near Lynn in Norfolk, which is either a variety of this with a large purpliſh flower, or the phoeniceum [y].]

β. Leaves of white Moth Mullein oblong, ſmooth, dark green. Stem three or four feet high, ſending out two or three ſide branches. Stem-leaves oblong, ſmooth, embracing. The flowers come out ſingly from the ſide of the ſtem, upon peduncles an inch long. Corolla white within, with a little bluſh of red on the outſide. Capſule round. Native of the South of France and Italy.

[13. Root biennial. Stem about two feet high, divided at the upper part into ſeveral branches ſpreading out at right angles. Leaves notched all round, cordate, obtuſe, lyrate at the baſe, and more pubeſcent than in V. nigrum. Flowers middle-ſized, yellow with purple-haired filaments. Native of Dauphiné. It ſeems to have been confounded with the nigrum, from which it differs principally in the leaves, the diſpoſition of the branches, and their pubeſcence [z].

14. Root biennial. Radical leaves repand, or obtuſely ſinuate-pinnatifid: ſtem-leaves oblong, waved, decurrent a little at the baſe on each ſide: branch leaves ovate or cordate, a little decurrent: the firſt of theſe are oppoſite, the reſt alternate [a].

Leaves tomentoſe; thoſe next the root elongated, waved, ſinuate-repand; thoſe on the ſtem ſeſſile, a little decurrent. Stem low, erect, tomentoſe. Branches numerous, ſlender, wand-like, erect, tomentoſe. Flowers ſeſſile, glomerate, in an interrupted ſpike. Corolla ſmall, yellow. Bractes cordate, acuminate, refracted [b].

Native of the South of France, Italy and Barbary. Mr. Miller ſays Italy and Greece, and alſo the rocks of Gibraltar.—He cultivated it in 1731. It flowers in july and auguſt [c].

Desfontaines has another ſpecies, which he names Verbaſcum cordatum. The leaves are thick, tomentoſe, hoary: the lower cordate, crenulate, obtuſe, petioled; ſtem-leaves half-embracing, acute, quite entire. Stem ſimple, or little branched, tomentoſe, erect, the thickneſs of a finger. He found it in Barbary about Tlemſen.

15. Stem erect, a foot high, tomentoſe at the baſe, becoming ſmooth by age, round, branched at bottom. Lower and ſtem-leaves petioled, two inches long, thickiſh, ſmooth above, tomentoſe beneath; ſegments unequal, oblong, obtuſe, having frequently a ſingle blunt tooth or two: leaves under the branches ſeſſile, gaſh-toothed. Flowers ſeſſile on the branches, alternate, remote, three or four together: floral leaves lanceolate, entire, longer than the calyxes. Calyx very tomentoſe hoary.

It differs from V. ſinuatum in having the leaves deeply divided and petioled. It ſeems doubtful whether it be different from Tournefort's plant referred to above. This was found in the iſlands of the Archipelago by Forſkahl.

16. Stem a foot high, ſmooth, quite ſimple, with a leaf or two at bottom. Radical leaves numerous, ſcarcely three inches long, petioled, lanceolate, toothſinuate or ſubpinnatifid, leſs deeply divided at the baſe, acute: ſegments lanceolate, toothed, the larger ſinuſes toothletted: ſtem-leaves entire. Peduncles from the bottom to the very top, ſolitary, remote, an inch long, one-flowered, floral-leaf cordate, ſmall, cuſped, at the baſe of each flower. Segments of the calyx unequal, three oblong, two roundiſh, larger, all ſlightly toothletted. Corolla yellow. Native of Spain, on hills towards Ortaleza; where it was found by Barnades.

V. Oſbeckii differs in having a leafy ſtem, the ſtem-leaves oblong, petioled, gaſh-toothed, the peduncles and calyxes woolly.—V. ſinuatum is diſtinguiſhed by having the radical leaves very blunt, and tomentoſe, the flowers ſeſſile and aggregate [d].

17. Stems ſpreading on the ground on all ſides, undivided, triangular, nervoſe. Leaves oval, cut into irregular ſegments: the upper ones ſmaller, almoſt ſeſſile; the lower petioled. Peduncles woolly, moſt of them bifid, from the bottom of the leaves. Calyx deeply five-cleft, woolly, with lanceolate ſegments. Filaments very ſhort reſting on a ſcale which covers the germ. Anthers oblong, erect, longer than the filaments. Germ almoſt round: ſtyle longer than the filaments: ſtigma entire and pointed. The whole plant had the ſmell of muſk. Native of Spain; where it was found by Oſbeck [e]. Introduced in 1775, by Monſ. Thouin. It flowers in july and auguſt. Biennial [f].

18. This is a ſhrub, half a foot high, ſtiff, and very much branched: branches alternate, round, tomentoſe, hoary: the lower ones becoming naked by age. Leaves ſeſſile, alternate, lanceolate, tomentoſe, attenuated at the baſe, obtuſe, with two blunt ſegments on each ſide at bottom: a bundle of flowers in the axils: leaflets wedge-ſhaped, entire. Raceme terminating, flexuoſe, branched at bottom, rigid. Peduncle ending in a ſpine. Pedicels rigid ſometimes one-flowered; (often inſtead of a pedicel a very ſpreading ſpine) alternate or oppoſite; under each a minute ovate bracte. Segments of the calyx ovate. Corolla ſmall, tomentoſe on the outſide. Capſule the ſize of a Coriander ſeed, ſmooth [g]. Native of Candia or Crete.]

19. Root perennial, compoſed of ſlender fibres. The leaves which ſpread flat on the ground, are of a thick fleſhy ſubſtance, of an ovate ſhape, indented on their edges, woolly, and of a dark green colour; they are ſeſſile or ſubſeſſile, embrace the crown of the root, and lie over each other; they continue in verdure all the year, but in winter change to a much darker green. From among theſe leaves ariſe ſeveral ſcapes or naked ſlender ſtalks, about four inches high, which divide into three or four pedicels at the top, hairy and of a brown-purpliſh colour, each ſuſtaining one large flower, of a fine blue, ſo deeply divided as to appear to be five-petalled; the ſegments are oval, obtuſe, and ſpread open flat, like the Auricula. Calyx funnel-ſhaped, cut into five obtuſe ſegments. Filaments thick, erect. Anthers flat, clinging to the ſtyle, as in Viola and Meadia. Capſule oblong-ovate.

[No one would have gueſſed from the habit of this plant

[r] Linn. ſyſt. [s] Gærtner. [t] Hort. kew. [u] Smith brit. [x] Engl. bot. [y] Idem. [z] Villars. [a] Linn. ſpec. [b] Desfontaines. [c] Hort. kew. [d] Vahl. [e] Oſbeck's voyage. [f] Hort. kew. [g] Vahl.

plant that it belonged to the Verbaſcums, moſt of which are tall and ſhowy, with leafy ſtems and long ſpikes of flowers generally yellow; whereas this is of very humble growth, its naked flowering ſtem even in gardens ſeldom exceeding ſix inches in height: its flowers are large in proportion to the ſize of the plant, of a bluiſh purple colour, and highly ornamental: they make their appearance in may, and continue ſucceſſively in bloſſom for ſeveral months. Hence this is a deſirable plant to cultivate, eſpecially for decorating rock-work.

It grows ſpontaneouſly on the Pyrenees: in its wild ſtate it is lower than in our gardens, with a more woolly foliage enriched with various tints [g]. It was cultivated by Mr. Miller in 1731 [h]. Mr. Curtis thinks that Parkinſon probably had it long before; but though he has figured and deſcribed it well in his Garden of pleaſant flowers, he does not give the leaſt hint that he poſſeſſed the growing plant. He places it with the Auriculas or Bear's-ears, rather in compliance with others, than from his own judgement.

Cluſius, in his ſecond appendix to his Hiſtory of plants informs us, that Venerius ſent it in the year 1600, from the Pyrenees, to John ab Hogelande, and Chriſtian Porret, at Bourdeaux.]

PROPAGATION AND CULTURE.

Moſt of the ſorts are biennial, and may be increaſed by ſowing their ſeeds in auguſt, on a bed of light earth, in an open ſituation, where the plants will ſometimes come up the ſucceeding month, and will endure the winter's cold very well, provided they have a dry ſoil. In february tranſplant them where they are to remain, not nearer than two feet aſunder. In june following they will flower and their ſeeds will be ripe in auguſt or ſeptember. But as the ſeeds frequently lie in the ground a whole year, the ground ſhould not be diſturbed. Theſe plants, as they require little care, may be allowed a place in the borders of large gardens, for the variety of their hoary leaves, and the ſweetneſs of the flowers, which have a ſcent ſomewhat like Violets. If the ſeeds be permitted to ſcatter, they will come up without care. The fourteenth ſeldom produces good ſeeds in England.

Ferrugineum (n. 8.) and phœniceum (n. 11.) have perennial roots, and not producing good ſeeds here, are increaſed by offsets, which ſhould be taken off in autumn, time enough to get good root before winter; otherwiſe they will not flower the following ſummer. Theſe plants thrive beſt in a ſandy loam, and ſhould be planted in an eaſt border, where they have only the morning ſun, for they do not thrive well when they are much expoſed to the ſun.

19. This alſo is perennial, and is uſually propagated by offsets, which come out from the ſide of the old plant; theſe ſhould be taken off in autumn, and planted in ſmall pots filled with light ſandy earth: they muſt always have a ſhady ſituation, for they will not thrive when they are expoſed to the ſun.

[It is very hardy, but requires a north aſpect in the ſummer, and to be carefully watered in dry weather. It will grow in almoſt any ſoil [i].

VERBASCUM. See *Buchnera, Buddlea, Celſia, Phlomis, Primula.*]

VERBĒNA. (*of Pliny. q.* Herbena. *Being the favourite herb uſed in the ſacred rites of the heathen. Or, according to Pliny, from* verro; *being uſed to ſweep and cleanſe Jupiter's table or altar for ſacrificing. Others derive it from* viriditas: *others again ſay it is q.* Veneris vena. *Such is the uncertainty of derivation.* In Greek it is Ἱερόβοτανη, *the ſacred herb, becauſe bunches of it were ſuſpended in luſtrations. Any herb uſed in the ſacred rites was called by theſe names.*)

Nat. Order of *Perſonatæ. Vitices* Juſſ.

[g] Curtis. [h] Hort. kew. [i] Curtis.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, angular, tubular, linear, five-toothed, the fifth toothlet truncate, permanent.

COR. one-petalled, unequal: *tube* cylindrical, ſtraight for the length of the calyx, then widening and curved in: *border* ſpreading, half-five-cleft: *ſegments* rounded, almoſt equal.

STAM. *Filaments* two or four, briſtle-ſhaped, very ſhort, lying within the tube of the corolla; two of them ſhorter (when there are four.) *Anthers* curved in, as many as there are filaments.

PIST. *Germ* four-cornered. *Style* ſimple, filiform, length of the tube. *Stigma* obtuſe.

PER. very ſlender, and ſcarcely manifeſt, or almoſt none. *Calyx* containing the ſeeds.

SEEDS two or four, oblong.

OBS. Sherardia Vaill. *contains the ſeeds and two anthers within a narrow calyx.*

V. lappulacea *bears echinated ſeeds and two anthers within an inflated calyx.*

Verbena Vaill. *produces obtuſe ſeeds and four anthers.*

ESSENTIAL CHARACTER.

Cor. funnel-ſhaped, almoſt equal, curved. *Cal.* one of the teeth truncate. *Seeds* two or four, naked or very thinly arilled. *Stam.* two or four.

SPECIES.

* *Two-ſtamened, two-ſeeded.*

DESCRIPTIONS, *&c.*

1. This ariſes with a ſhrubby ſtalk near three feet high, divided into three or four branches. Leaves oblong-ovate, placed by pairs, deeply ſerrate, deep green above, but hoary beneath; their foot-ſtalks are ſhort, and have leafy borders running from the baſe of the leaves. The flowers grow in thick terminating ſpikes about a foot in length; they are large, of a fine blue colour, and have ſmall acute-pointed leaves intermixed with them. They come out in june and july, and when the ſeaſon proves warm, the ſeeds ripen in autumn. It is biennial, and a native of South America. The ſeeds were ſent to Mr. Philip Miller by Mr. Robert Millar, from Panama.

2. [This is an annual plant, very much reſembling the jamaicenſis, but eaſily diſtinguiſhed from it by the ſtem and branches being ſmooth, except the baſe of the leaves and the part of the branches between the leaves, which are ciliate. The leaves alſo are much narrower, being truly lanceolate and drawn to a point at both ends. The ſpike is the ſame, but the colour of the corolla is purple *.

Linneus diſtinguiſhes this from the next ſpecies, by the ſtem being green, and the leaves being waved, and not at all ciliate. Whereas in that the ſtem is purple, and the leaves ſerrate, and ciliate at the baſe.

* Jacquin.

Digitized by Google

Native of Ceylon. Flowers in auguſt, and was cultivated by Mr. Miller in 1732[l]. But Mr. Miller's indica ſeems to be the jamaicenſis; for he ſays it is a native of moſt of the iſlands in the Weſt Indies, and quotes Sloane's name. What he calls jamaicenſis (n. 12.) he ſays is a perennial plant, with ſhorter ſpikes, and ſmall white flowers, and that it was ſaid to come from Senegal in Africa. Here is ſome unaccountable blunder; but it cannot be the jamaicenſis of Linneus.

3. Stem three or four feet high, very much branched and diffuſed, and being ſuffruteſcent at the baſe it ſeems to be more than annual. Stem and branches rough with hairs. Leaves oppoſite, ovate, obtuſe or acute, ſerrate, gradually and for a conſiderable length attenuated at the baſe. From the axil between two oppoſite branches comes forth a fleſhy ſpike, a foot long, unequally cylindrical, ſtiff and green; the flowers blow in ſucceſſion, beginning at the bottom, very few together, violet-coloured, with the throat and long ſlender incurved tube white: Anthers ſulphur-coloured. After the corolla is fallen, the ſtyle ſtands out of the ſpike[m].

After each flower follows in a greeniſh-brown calyx or huſk, one ſeed or rather huſk, ſomething like wheat in ſhape and colour, only ſmaller, and eaſily diviſible into two, both being cloſe covered with the ſame membrane: they are in a cavity on the ſide of the ſpike, and are covered with three ſharp, browniſh, membranous leaves.

Native of Jamaica, Barbadoes, and other iſlands of the Weſt Indies.

It is much uſed in clyſters for the belly-ach, and by ſome in poultices, with onions, for the dropſy. A decoction of it with or without Lime-roots, drank very warm, is counted a powerful ſudorific, and good in the dropſy. It is much in repute among the Indians and Negroes, for the cure of moſt diſeaſes[n]. Jacquin remarks that the plant has an herbaceous taſte, ſomewhat like the green pod of the kidney-bean, with a ſlight pungency on the tongue.

Cultivated in 1714, by the Dutcheſs of Beaufort. Biennial[o].

4. This is an upright branchy ſhrub with a ſomewhat ſquare trunk of about ſix feet high; the younger branches are ſharply tetragonal, greener, and more villoſe: the leaves are oppoſite, ſoqtſtalked, ovate, ſharp, ſerrated, wrinkled, roughiſh and villoſe above, tomentoſe beneath: their length is about five inches: the ſpike is terminal, fleſhy, cylindric, ſomewhat villoſe, leafleſs, and at length about a foot and half long: the flowers are at firſt extremely deep ſcarlet, and afterwards roſe or fleſh-coloured: the bractes are longer than the calyxes, green, villoſe, and upright, with the two exterior teeth longer than the reſt and ſetaceous. Native of South America[p].

5. This is a ſhrub, with four-cornered branches, of a ſomewhat aſh-coloured purple colour. Leaves oppoſite, on ſhort petioles, an inch and half long, attenuated to both ends, acute at the tip, equally ſerrate, quite entire at the baſe, having minute villoſe hairs ſcattered over them, nerved above, nerved and veined beneath; nerves hoary. Spikes terminating, often half a foot long, imbricate. Bractes ovate, ſubciliate, acuminate, drawn out into an awn almoſt as long as the bracte. Rachis hollowed out alternately. Calyx ſhorter than the bracte: flowering calyx ſpreading a little and curved outwards; fruiting concealed within the cavity of the rachis, angular, the ſide oppoſite to the cavity of the rachis convex, the other flat and margined. Style twice as long as the calyx: ſtigma ſlightly bifid. Seeds two.—It differs from V. mutabilis in having the leaves gradually narrowing into the petiole, not ſuddenly acuminate; the bractes ovate, ending in an awn, not lanceolate and acute; the calyxes ſhorter than the bracte. Found in South America by von Rohr[q].

6. This is a ſhrub growing in the Caribbee iſlands: the ſtem and branches are round, ſmooth, and armed with ſtraight, ſcattered, black ſpines: the leaves are bipinnate, often of four pair, ſometimes of five or three; with an uncertain number of pinnules, twelve, more or leſs: they are linear-oblong, ſharpiſh, ſmooth, ſubſeſſile, and ſmall: the racemes are lax, terminal, and axillary; about half a foot long; with the proper foot-ſtalks about two inches long, ſpreading, and at the tips collecting the flowers, which are of a pale yellow, into a roundiſh head: they are ſeſſile, and of a fragrant ſmell.

Native of Jamaica. Annual[r].]

7. This has a ſhrubby ſtalk, which riſes five or ſix feet high, and divides into ſeveral branches. Leaves ſeſſile, oblong, ſerrate, ending in acute points, two inches long, one inch broad near the baſe, of a light green colour on both ſides. The branches are terminated by ſlender looſe ſpikes of ſmall pale flowers, the calyxes of which afterwards become ſwelled and almoſt globular; they are reflexed, and ſet with ſtinging hairs.

[Stem four-cornered, rugged at the edges. Branches oppoſite, dichotomous at top. Racemes at the forks long. Leaves cordate, oblong, rugged, on very ſhort petioles[s].

The leaves, ſtem, and eſpecially the ſeeds are ſo hiſpid as to adhere obſtinately to the fingers and clothes. Flowers pale purple. Spikes moſtly three together, from a long ſpan to a foot or even two feet in length, unbranched. Seeds two, incloſed in a hiſpid calyx, reſembling the fruit of Galium Aparine. At firſt they are erect and quadrangular, but afterwards become round, and hang down, ſo that many of the ſeeds fall out. Native of Mexico. It flowered in the Eltham garden in 1726, in ſeptember; but in the following years in july and auguſt[t].

Gærtner deſcribes the two ſeeds as bony, united into an ovate globule, on one ſide convex and tubercled, on the other ſmooth, flattiſh or ſlightly concave, pale; they are faſtened to the bottom of the calyx, which covers them, and ſerves for a pericarp.]

It flowers late, but in good years the ſeeds ripen in England.

8. This riſes with a ſhrubby branching ſtalk five or ſix feet high. Leaves oppoſite on ſhort foot-ſtalks, lanceolate, two inches long, and half an inch broad, ſerrate, the teeth of the jags coming from the point of a fold or plait. Flowers on long naked ſtalks from the axils, blue, and collected in oval heads. They appear late in autumn, and unleſs the ſeaſon prove warm the ſeeds rarely ripen in England; but the plants may be kept two or three years in a warm ſtove.

[Browne ſays it is biennial or triennial, and ſtretches by a ſlender woody ſtalk to the length of five or ſix feet. It has a great number of oblong ſerrate veined leaves, that have a fine down underneath.

Native of Jamaica, and the continent of America.]

Mr. Miller had the ſeed from La Vera Cruz by Dr. Houſtoun. He therefore cultivated it before 1733, in which year Dr. Houſtoun died.

[9. This is a fragrant ſhrub. Stem erect, branched, aſh-coloured, the height of a man. Branches erect, round, like the ſtem. Branchlets rugged, pithy, bay-coloured. Shoots villoſe, rugged, from four-cornered round, green at top. Leaves oppoſite, ſeldom three together, ſpreading, ſharp at both ends, crenate or bluntly ſerrate, except at the baſe, where they are entire, attenuated into the petiole, marked with lines above, and with erect, alternate, prominent nerves beneath, very much veined, wrinkled, villoſe, rugged, reclining, permanent, fragrant. Petioles ſhorter than the leaf, round on one ſide, grooved or flat on the other, villoſe, edged with the decurrent leaf. Heads terminating, axillary, peduncled, roundiſh, bracted, imbricate. Peduncles erect, ſingle or two from each axil, ſcarcely longer than half the leaf, villoſe, rugged. Flowers ſeſſile, one to each bracte, very cloſe, compreſſed, white. Bractes imbricate, ovate, acute, hirſute, longer than the calyxes, permanent. Calyx two-parted, compreſſed, very ſmall: ſegments roundiſh, one ſometimes two-toothed, concave, erect, hirſute; becoming two roundiſh concave membranaceous villoſe arils, each clothing one of the ſeeds, which are hemiſpherical, preſſed cloſe, flat on one ſide, gibbous and ſmooth on the other. The perianth becomes a bipartile or two-leaved aril not only in this, but in mexicana and nodiflora.

[l] Hort. kew. [m] Jacquin. [n] Sloane. [o] Hort. kew. [p] Jacquin. [q] Vahl. [r] Jacquin. [s] Linn. ſpec. [t] Dill. elth.

This

This ſpecies differs from V. ſtoechadifolia in having flat lanceolate leaves, whereas in that they are linear and plaited:—from V. triphylla in having the flowers in heads, not panicled, the leaves oppoſite, not in whorls:—from V. nodiflora, in having a ſhrubby ſtem. Native of South America, probably about Buenos Ayres. Cultivated many years back in the Paris garden; where it is in flower or fruit the whole year [u].

10. Spikes ſubcylindrical, thicker at the baſe. Calyx, when ripe, two-valved. Seeds united into a globe, plano-convex, ſmooth, whitiſh [x]. Native of Java.

11. Roots ſimple, filiform. Stems herbaceous, creeping, aſcending, from three inches to a foot in length, ſubdivided, roundiſh, marked with lines, ſmooth. Leaves oppoſite and decuſſated, on ſhort petioles, cuneate-obovate, ſerrate-toothed, nerved, thickiſh, ſmooth on both ſides, having pores underneath. Peduncles ſolitary, terminating, erect, angular. Spike terminating, roundiſh, compoſed of ſmall whitiſh or roſe-coloured flowers, ſeparated by bractes, which are ſeſſile, imbricate, ſquare, acuminate, concave, coloured. Calyx compreſſed a little, two-toothed: teeth erect, keeled, ciliate at the back. Tube of the corolla longer than the calyx, but ſcarcely curved in: border ſlightly five-cleft; the upper ſegment emarginate, almoſt upright, ſhorter; the anterior ones equal, ſpreading; the middle one three-notched. Anthers twin, yellow. Germ two-grooved: ſtyle ſhort, thick: ſtigma ſubcapitate, green. Seeds two, roundiſh, flatter on one ſide, covered by a membrane forming a ſort of thin capſule [y]. Native of the four continents: found near Naples, and in the iſland of Sicily; in the Eaſt Indies and the iſland of Ceylon; in Barbary near Caſsa; in America in the province of Virginia, and ſome of the Weſt India iſlands; and in the iſle of Tanna in the South ſeas. Mr. Miller had the ſeeds from Jamaica by Dr. Houſtoun; he therefore cultivated it before 1733.]

12. This has four-cornered ſtalks which riſe to the height of five or ſix feet, ſending out ſide branches by pairs. Leaves three inches long, and about three quarters of an inch broad, of a pale green colour, and ſerrate. Spikes terminating, cluſtered, the longeſt about two inches, the others about half as long. Flowers blue, appearing late in ſummer, and not often ſucceeded by good ſeeds in England.

[Seeds four, oblong, on one ſide a little convex, ſtriated, ferruginous, on the other ſomewhat angular, whitiſh, rugged with minute calloſe dots, ſurrounded by a prominent rim [z].

Native of Buenos Ayres. Firſt raiſed in the Eltham garden from ſeeds taken from dried ſpecimens ſent from thence. The flowers are ſmall, ſlightly curved in, tinged with purple [a].]

13. This ſends up many four-cornered furrowed ſtalks from the root, which riſe five or ſix feet high. Leaves oppoſite, oblong, about three inches long, and an inch broad near the baſe, ending in acute points, deeply ſerrate on ſlender petioles. From the ſame joints come out ſhort branches, ſet with ſmaller leaves of the ſame form. The ſtalks are terminated by ſpikes of blue flowers in cluſters, which appear in auguſt; and if the autumn prove favourable, the ſeeds will ripen about the middle of October. Native of Canada. Mr. Miller ſays it grows naturally in moſt parts of North America.—[It was cultivated by him in 1731 [b].

14. This is a very ſweet-ſmelling under-ſhrub. Stem upright, branched, round, aſh-coloured, a fathom in height. Branches three or four in a whorl, ſpreading very much, rugged. Branchlets ſix-cornered, bay-coloured. Leaves generally three together, ſometimes four, ſpreading, linear-lanceolate, ſharp at both ends, entire, ſcarcely apparently muricate on the upper ſurface and eſpecially at the edges, rugged, nerved; the nerve channelled above, prominent beneath; nervelets ſpreading, parallel, ſimple; of a bright green-colour, and very pleaſant ſmell like that of the lemon. In younger plants the leaves are lanceolate, looſely toothed or ſerrate. Petioles very ſhort, round on one ſide, channelled on the other. Flowers in an erect terminating panicle, compoſed of ſpikes, ſtriated, villoſe, bracted, with a few leaves intermixed at bottom. Spikes whorled by threes, ſpreading; the lower ones axillary; the upper ones ſometimes vertically double. Each flower is erect, ſeſſile, very pale violet, ſweet. Bractes ovate, acuminate, concave, under the flowers; and there are other ſmaller ones under the ſpikes. Calyx four-toothed, villoſe, duſky: ſegments acute, erect, Tube of the corolla pubeſcent, hairy within, violet, length of the calyx: border four-parted, ſpreading, nearly equal; ſegments roundiſh, obtuſe, ſomewhat waved: the upper one ſimple, entire or bifid, the lower three-parted, wider but ſcarcely longer. Anthers ovate, acute, two-celled, the lower within the throat, the upper within the tube. Germ ſuperior, twin obovate, two-grooved, villoſe, duſky: ſtyle ſhorter than the ſtamens: ſtigma thickiſh, ſubbilobate. Pericarp none; but the calyx contains the ſeeds at its bottom, and is two-valved and ſplits from back to front. Seeds two joined, but ſeparating like the calyx, oblong, flat, and hoary on one ſide, rounded and pubeſcent on the other.—It is known by its ſhrubby ſtem, leaves in whorls, flowers in panicles, its four ſtamens and two ſeeds, and the ſmell of the whole plant like lemon.

Native of South America. Found in Chili by Dombey, and by Commerſon at Buenos Ayres; whence it was introduced into the Spaniſh gardens, where it flowers in the open air. Ortega and Palau, profeſſors of botany at Madrid firſt deſcribed this plant, and named it Aloyſia in memory of Louis Prince of the Aſturias [c]. It was introduced here in 1784, by Profeſſor John Sibthorp, who obtained it at Paris, on his return from Greece.

Monſ. L'Heritier has ſubdivided the tetrandrous Vervains from the ſeed. This and globiflora, ſtoechadifolia, and nodiflora have two ſeeds: bonarienſis, haſtata, carolina, urticifolia, officinalis, ſupina and Aubletia have four ſeeds.

15. Stem herbaceous, a foot high, erect, ſomewhat branched, brittle, quadrangular, more contracted at the baſe of the petioles, ſtriated, pubeſcent. Leaves oppoſite and decuſſated, ovate, acute, ſerrate, nerved, hiſpid, on four-cornered pubeſcent petioles. Racemes long, looſe, compoſed of ſcattered flowers, directed one way, of a very pale blue colour, on ſhort pedicels, having minute bractes under them. Calyx equal, hiſpid. Corolla almoſt equal: tube twice as long as the calyx; ſegments of the border acute, three ſuperior a little diſtinct, two inferior. Germ ovate: ſtyle ſhort: ſtigma globular. Capſule four-cornered, ſpiny at the corners, ovate at the baſe, bipartile, four-celled, covered with the inflated calyx. Seeds four, oblong [d].

The obtuſe ſtigma is reflected. Each of the ſeeds is two-celled, and contains two kernels [e].

In the Weſt Indies it is reputed a fine vulnerary and ſubaſtringent, and is commonly applied to bleeding wounds in men or cattle by the inhabitants of the country in Jamaica; where it is thought to be ſo powerful a ſtyptic or aſtringent, as to ſtop the hæmorrhage even when ſome of the more conſiderable arteries are cut; and it may be eſteemed an excellent application in all manner of ſores, where the habit is relaxed [f]. Native of the Weſt Indies, in ſtony waſte places. Different enough, according to Loefling, Houſtoun, &c. to form a diſtinct genus.

16. Stem herbaceous, erect, four-cornered, ſmooth. Leaves petioled, thoſe on the ſtem ovate, thoſe on the branchlets oblong; all rugged, ſomewhat ſtrigoſe, obtuſely ſerrate, acute. Racemes terminating, quite ſimple, a foot long. Flowering calyxes ſpreading very much, villoſe, attenuated to both ends, ſhortly pedicelled; having a briſtle-ſhaped bracte, the length of the pedicel: fruiting calyxes reflexed, roundiſh, terminated by a neck, villoſe. Seeds two, cohering, rounded, compreſſed, very much wrinkled, having two or three ſmall teeth on the outer ſides.

Very nearly allied to the preceding, but more robuſt, the ſtem ſtiffer, the leaves more rugged above, the ſerratures of the leaves deeper, the ſeeds not oblong and echinate, but roundiſh and toothed, convex on the outer ſide, and bent in at the tips. In the calyx it approaches

[u] L'Heritier. [x] Gærtner. [y] Swartz. [z] Gærtner. [a] Dill. elth. [b] Hort. kew. [c] L'Heritier. [d] Swartz. [e] Jacquin. [f] Browne.

Digitized by Google

proaches to the mexicana, but the ſeeds are not hiſpid. Native of Arabia Felix [s].]

17. Root perennial. Lower leaves heart-ſhaped and rough, five inches long, and three inches and a half broad near the baſe, ending in acute points; they are of a dark green colour and ſerrate. The ſtalks riſe ſix feet high, are four-cornered, branch towards the top, and are terminated by ſlender ſpikes of white flowers, formed into panicles.

[According to Dillenius, the ſtem is only a foot and half or two feet high, obtuſely quadrangular; the lower leaves reſemble thoſe of Baulm, all are rough to the touch, though they are not very hairy, except on the lower part; the flowers are ſmall, pale ſlightly tinged with purple, divided into five ſegments which are nearly equal; the ſeeds are oblong, ſmooth, black when ripe. Native of Carolina.] Mr. Miller ſays, the ſeeds were ſent him from Philadelphia, by Dr. Benſel, and he does not quote the Hortus Elthamenſis.

18. Stems four-cornered about three feet high. Leaves three inches long, and an inch broad in the middle, ending in acute points, ſerrate, and placed by pairs. Panicles terminating, long, ſlender, compoſed of ſmall white flowers ranged looſely, appearing in july, and ſucceeded by ſeeds which ripen in autumn. Native of moſt parts of North America. [Cultivated by Mr. Miller in 1731 [h]. He ſays it is biennial; but it is marked in Linneus and the Kew Catalogue as perennial.

19. Stem herbaceous, erect, four-cornered, villoſe. Leaves petioled, the lower oppoſite, the upper alternate, an inch and half long, diminiſhing gradually upwards, ovate, groſsly and equally ſerrate, acute, the upper ſurface rugged with minute raiſed dots, marked with lines along the nerves, beneath leſs rugged, villoſe along the nerves. Spikes from the uppermoſt axils, ſolitary; the terminating one elongated, with three branches at the baſe that are much ſhorter, filiform. Flowers alternate or oppoſite, copious, ſmall, approximating. At the baſe of the calyx a briſtle-ſhaped bracte. Fruiting calyx ſcarcely bigger than a muſtard ſeed, angular. Seeds four, ſmooth, linear-three-ſided, ſlightly wrinkled at the back. Allied to Verbena urticifolia. Native of South America, where it was found by von Rohr [i].

20. Root annual, (or rather biennial.) Stem a foot high, (or ſeldom more than two feet in our gardens,) erect, four-cornered, ſomewhat hiſpid, dichotomous, brachiate. Branches from each axil. Leaves oppoſite, petioled, ſubcordate, ſublobate, gaſh-ſerrate, wrinkled, ſomewhat rugged. Stipules none. Spikes terminating, ſolitary, oblong, peduncled: flowers in bundles. Bractes linear, the length of the calyx, to each. Calyx five-cornered: teeth acute, the two upper ones ſhorter. Tube of the corolla filiform, twice as long as the calyx: throat gibbous downwards, cloſed by hairs: border flat, almoſt equal; ſegments oblong, emarginate, obtuſe, blood-red. Two ſtamens in the throat, two within the tube. Stigma thickiſh, bifid; the lower ſegment acute. Seeds four, cloſe, ſhorter than the calyx. Linneus had firſt made it a Buchnera; but it differs from that genus, in having four, diſtinct, naked ſeeds. Native of America [k].—Introduced in 1774, by Monſ. Richard. It flowers in june and july [l]. The extreme brilliancy of its colour renders it a very ornamental greenhouſe plant [m].]

21. Root biennial. Bottom leaves ſix inches long, deeply jagged, and ſerrate, rough, and of a deep-green colour. Stalks two feet high, having a pair of ſmaller leaves of the ſame ſhape at each joint. The upper part branches out into numerous foot-ſtalks, forming panicles of blue flowers; appearing in july and auguſt. If the ſeaſon prove favourable, the ſeeds will ripen in autumn. Native of North America.] Cultivated by Mr. Miller in 1759.

22. Root perennial, branching, woody. From each of its ſummits riſes a ſingle ſtem, curved at the baſe, then erect, from one to two feet high, ſquare, leafy, rough with little prickles, panicled at the top with ſeveral oppoſite ſlender ſpikes of flowers. Leaves oppoſite, deeply cut and jagged; the uppermoſt three-cleft or ſimple. Spikes terminating in pairs, forming a panicle. Flowers many, ſmall, ſeſſile, each accompanied by a little bracte. Calyx rough. Corolla very pale lilac; its tube incloſing the four ſhort curved ſtamens. Seed when young enfolded in one common ſkin, which is almoſt obliterated as they ripen, and then each appears marked with excavated dots at its upper part [n].

Native of Europe, Barbary, China, Cochinchina and Japan. With us, by road ſides, in dry ſunny paſtures and waſte places about villages.] Mr. Miller remarks, that although Vervain is very common, yet it is never found above a quarter of a mile from a houſe, which has occaſioned its being called Simpler's Joy. It is indeed pretty general near the entrances into towns and villages, but it is by no means confined to ſuch ſituations, and Dr. Withering obſerves, that it is very plentiful at the foot of St. Vincent's rocks, all along the courſe of the river. It begins to flower in july, and continues through the autumn.

Among the ancients, the Verbena was held ſacred, and was employed in making leagues, by ambaſſadors, in ſacrificial rites, and in incantations; hence it was ſuſpended about the neck as an amulet, and was thought to be good againſt ſerpents and venomous bites, and was recommended as a ſovereign medicine for a variety of diſeaſes [o].

Though Vervain is deſtitute of odour, and manifeſts to the taſte but a ſlight degree of bitterneſs, and aſtringency, yet even in modern times it has been accounted a ſovereign remedy in a multitude of diſorders. Schroder recommends it in upwards of thirty complaints. Bruiſed and appended to the neck, it was uſed in inveterate head-achs, and Foreſtus relates a remarkable inſtance of its ſervice in this reſpect. In ſtill later times we are told that the moſt ſevere and obſtinate head achs have been cured by applying it as a cataplaſm. It has however fallen into diſuſe in Britain, nor has Mr. Morley's pamphlet, written profeſſedly to recommend its uſe in ſcrophulous caſes, had any effect in reſtoring its medical character. He directed the root to be tied with a yard of white ſattin ribband round the neck, and to remain there till the patient recovered. But he had recourſe alſo to infuſions and ointments prepared from the leaves of the plant; and occaſionally called in the aid of the moſt active medicines of the Materia Medica [p].

This ſpecies having four ſtamens, two of which are longer than the two others, our Engliſh authors have placed it in the claſs Didynamia. And the majority of the ſpecies having four ſtamens, they would all ſeem more naturally to appear in that claſs, among other plants to which they are cloſely allied [q].]

β. The Portugal variety, noticed by Tournefort, is taller, the leaves are broader, and the flowers larger. Mr. Miller himſelf does not think it ſpecifically different from the common ſort.

23. Root biennial, (others ſay annual.) Stalks near two feet high, branching out greatly. Leaves ſeſſile. Flowers diſpoſed in long looſe ſpikes ſingly at the end of the branches; they are of a light blue colour, and larger than thoſe of the common ſort. It flowers in july and auguſt, and the ſeeds ripen in autumn.

[Stem roundiſh, compreſſed a little, and ſomewhat pubeſcent. Flowers blueiſh [r].

It is allied to the common ſort, but is much ſmaller; and differs in having the ſtems proſtrate and villoſe; the leaves ſmall and pinnatifid-laciniate; the flowers more cloſely cluſtered and only half the ſize. Desfontaines obſerved a variety in the Paris Garden that was erect and almoſt ſmooth [s].

Native of Spain, Portugal and Algiers.—It appears from Parkinſon, that it was cultivated here in 1640 [t].

Mr. Miller has ſome other ſpecies from America, all diandrous or belonging to the firſt ſection.]

24. Verbena americana. *Panama Vervain. Mill. dict. n.* 10.

Sherardia americana, verbenæ folio ſubrotundo craſſo, floribus cæruleis, ſpica longiſſima & craſſiſſima. *Millar.*

Two-ſtamened, ſpikes fleſhy almoſt naked, leaves ovate obtuſe indiſtinctly crenate petioled.

Annual. Stalks about a foot high. Leaves on long foot-ſtalks, and from the ſame joints branches ſuſtaining three or four ſmall leaves of the ſame ſhape; they are of a light green colour. The ſtalks are terminated by thick fleſhy ſpikes of blue flowers, which appear late in autumn, ſo that unleſs the ſeaſon prove warm, the ſeeds will not ripen in England. They were ſent him from Panama, where it grows in moiſt places.

25. Verbena ſenegalenſis. *Senegal Vervain.*

V. jamaicenſis. *Mill. dict. n.* 12.

Two-ſtamened, ſpikes ſhorter, leaves ovate ſerrate hoary underneath.

Perennial. Stalk branching, near two feet high. Leaves in pairs, two inches and a half long, and almoſt two inches broad, deep green above but hoary underneath, on pretty long foot-ſtalks. Flowers in fleſhy ſpikes at the end of the branches; theſe ſpikes are ſhorter and not ſo thick as thoſe of the former ſorts. The flowers are ſmall and white, and make no great appearance: they appear in june and july, and the ſeeds ripen in autumn, but the plants may be preſerved two or three years in a warm ſtove. The ſeeds were ſent from Paris, and were ſaid to come from Senegal in Africa. It cannot be the ſame with jamaicenſis, n. 3.

26. Verbena fruticoſa. *Shrubby Vervain. Mill. dict. n.* 14.

Sherardia nodiflora fruticoſa, foliis ſubrotundis ſerratis, *Houſtoun MSS.*

Two-ſtamened, ſpikes round, leaves ovate ſerrate, ſtem ſhrubby branched.

Stem three or four feet high. Leaves oppoſite, of a light green colour, about an inch and half long, and near an inch broad. Flowers pale blue, collected into oval heads, ſtanding upon long naked axillary peduncles. They come out late in autumn, and are not followed by ſeeds in England. Found at Campeachy by Dr. Houſtoun, who ſent the ſeeds to England.

27. Verbena anguſtifolia. *Narrow-leaved Vervain. Mill. dict. n.* 15.

Sherardia ſpicata, folio anguſto ſerrato, flore cæruleo. *Houſt. MSS.*

Two-ſtamened, ſpikes fleſhy almoſt naked, leaves linear-lanceolate indiſtinctly ſerrate.

Annual. Stalk branching, a foot and half high. Leaves pale-green, three inches and a half long, and half an inch broad, ending in acute points. The branches are terminated by fleſhy ſpikes of blue flowers, appearing in auguſt, and in warm ſeaſons producing ſeeds. Found at La Vera Cruz by Dr. Houſtoun, who ſent the ſeeds.

28. Verbena rugoſa. *Wrinkled-leaved Vervain. Mill. dict. n* 18.

Sherardia arboreſcens nodiflora foliis ſerratis & rugoſis, flore purpureo. *Houſt. MSS.*

Two-ſtamened, ſpikes ovate, leaves roundiſh ſerrate and wrinkled, ſtem ſhrubby branched.

This has a ſtrong woody ſtalk, ten or twelve feet high, covered with a light-brown bark, and ſending out many woody branches on every ſide. Leaves of a light green colour, on ſhort foot-ſtalks. Flowers ſmall, pale blue, collected into ovate heads, and ſtanding on naked axillary peduncles. They ſeldom appear in this country, and do not produce ſeeds here. It was diſcovered by Dr. Houſtoun growing naturally at Campeachy, whence he ſent the ſeeds to England.

PROPAGATION AND CULTURE.

1. 2. 3. 4. 5. 6. 7. 8. 9. 10. 11. 12. 15. 19. 24. 25. 26. 27. 28. Theſe being natives of hot climates, (chiefly South America and the Weſt Indian iſlands,) require care and protection. The ſeeds ſhould be ſown upon a hot-bed early in the ſpring, and when the plants are fit to remove, they ſhould be each tranſplanted into a ſeparate ſmall pot, and plunged into a freſh hot-bed, to bring them forward, ſhading them in the day time with mats until they have taken new root, and then treating them as other tender plants from the ſame countries.

The annual ſorts muſt be kept in the ſtove or a good glaſs caſe, when they are become too tall to remain longer under the frames; for if they are placed abroad in the open air, they will not ripen their ſeeds here, unleſs the ſummer be very warm: and where there is a conveniency of having a bark-bed in a glaſs-caſe, for plunging ſome of theſe tender annual plants, they will thrive much better; and come to greater perfection than thoſe which are placed on ſhelves.

The perennial ſorts may be kept in ſuch a glaſs caſe till autumn, allowing them a large ſhare of air in warm weather, to prevent their drawing up weak, as they increaſe in ſize; but this muſt be done with caution. If they be put into pots too large, they will not thrive.

Such of theſe as do not produce ſeeds here, may be increaſed by cuttings during the ſummer months, and may thus be preſerved many years in a good ſtove.

13. 17. May be propagated by ſeeds ſown in autumn, or by parting their roots at the ſame ſeaſon. They are hardy enough to thrive in the open air, and love a ſoft loamy ſoil not too dry.

[14. This elegant ſhrub, ſo delightful for its fragrance, may eaſily be increaſed by cuttings, and requires only the protection of a good greenhouſe or glaſs caſe. Mr. Curtis ſuggeſts, that in ſome parts of our iſland, eſpecially near the ſea, it would in all probability ſucceed very well in the open border. Monſ. L'Heritier informs us, that it bears the open air very well in Spain, and that it may be increaſed by ſeeds and ſuckers as well as cuttings.]

18. 21. 23. Sow the ſeeds in autumn: keep them clean from weeds, and thin the plants when they are too cloſe. Or if the ſeeds be permitted to ſcatter, the plants will come up the following ſpring.

[20. In favourable ſeaſons this ripens its ſeeds readily, and by them it is uſually propagated, being a biennial. It is preſerved in the green-houſe [a].

Leaves trifid-laciniate ſerrate, ſtem creeping.

[12. Verbeſina Boſvallea.
Lin. ſyſt. 780. *ſuppl.* 379.
Leaves multifid-capillary, ſtems proſtrate, florets ſix, female one.

DESCRIPTIONS, &c.

1. This is a herbaceous plant, with an upright ſtem about two feet high, ſubdivided, round, winged, rough-haired. Branches alternate, erect, axillary. Leaves oblong, acuminate, angular-toothed, nerved, ſomewhat rugged, rough-haired. The ſtem has four wings formed by the leaves running down it; hence its trivial name. Peduncles elongated, terminating, pubeſcent, with flowers in ſingle heads, of a deep orange colour. Common calyx ſubimbricate: the outer ſcales longer, obtuſe, linear; inner ſhorter, membranaceous. In the hermaphrodite florets the ſtyle is cloven at the tip, and the ſtigmas are thicker and compreſſed. The female florets in the ray are numerous, ovate, and emarginate; the germ ovate, margined; the ſtyle cloven; and the ſtigmas reflexed. All the ſeeds are obovate, wedge-ſhaped, with white membranaceous wings; pappus two-awned; one awn longer than the other, hooked. Chaffs of the receptacle linear, acute, membranaceous, compreſſed [x].

Gærtner remarks, that the leaflets of the calyx are ſcarcely to be diſtinguiſhed from the chaffs of the receptacle, which is oblong, nearly awl-ſhaped; that the petal of the radial florets are ſhorter than the diameter of the diſk; that the chaffs are oblong, concave, pubeſcent on the outſide; that the ſeeds are obovate, compreſſed, brown with a pale rim; that the awns of the pappus or ſeed-crown are briſtle-ſhaped, the longer incurved, the ſhorter ſtraight: and that this genus is Spilanthus with the addition of a ray.

This is a perennial plant; though Mr. Miller ſays it is annual.

Native of South America, and the iſlands; common in Jamaica, Curaſſao, Surinam, &c.—Cultivated in 1714, by the Dutcheſs of Beaufort. It flowers moſt part of the ſummer [y].

Linneus remarks, that it differs very much in habit and ſtructure from the other ſpecies, and perhaps might form a diſtinct genus.

2. This is a ſhrub, with a ſingle, round, ſubtomentoſe ſtem and undivided branches from the upper axils of the leaves; which are ſomewhat tomentoſe, bluntiſh, petioled. Flowers terminating, ſolitary, peduncled. Calyx hemiſpherical, imbricate, tomentoſe. Corolla yellow: florets of the ray lanceolate, entire, many; of the diſk abundant, ſeparated by chaffs. Seeds crowned with a rim and four ſmooth briſtles. Found in China by Oſbeck [z]. By the Chineſe called Kaling-fa [a].

3. Native of Virginia.

4. Native of Jamaica [b].

Cavanilles, in his Icones plantarum in Hiſpania, p. 67. n. 109. t. 100. has a different ſpecies under this name which he ſays came from Mexico, and flowered in the Royal garden at Madrid, in december, january and february.

He characterizes it by having oppoſite, pinnatifid leaves, running down the ſtem, and the flowers in corymbs.

The ſtem is a fathom high, round, ſomewhat tomentoſe, putting forth oppoſite branches. Leaves ſomewhat rugged, narrowed at the baſe, each border decurrent and forming a curled wing, ſo that the ſtem is four-winged: the ſegments of the leaves are ſerrate. The flowers are numerous, forming corymbs at the top of the ſtem and branches. Calyx obovate, imbricate; ſcales ovate-acute, brown at the tip, the inner ones longer. Corolla yellow: females in the ray about fourteen, linear, trifid, with the middle toothlet ſhorter. Germ in all ſmall, turbinate: ſtigmas revolute, yellow. Receptacle flat: chaffs the length of the florets, keeled, oblong, with a ſharp point. Seeds ovate, emarginate and crowned with two fine awns; the central ones girt longitudinally with two wings, thoſe of the ray with three.

Cavanilles remarks, that by theſe winged ſeeds this plant approximates to Buphthalmum, and that the habit, receptacle, flowers, and ſeed-crown direct that it ſhould be placed at the end of the Verbeſinas.

5. Stem upright, about three feet high, rough with horizontal hairs, and about the thickneſs of a ſwan's quill towards the root: it is of a purple colour marked with green ſpots: branches oppoſite and decuſſating; dividing at their upper part, and ſpotted with green and purple: leaves ovate, of about a palm's length, obtuſely and unequally ſerrated at ſome diſtance from the baſe and continuing ſo to the tip: they are ſharp-pointed, of a pale green, tomentoſe, three-nerved, and veiny, horizontal or ſlightly depending: the foot-ſtalks

[x] Swartz. [y] Hort. kew. [z] Linn. ſpec. [a] Oſbeck. [b] Swartz. [c] Murray.

are

Digitized by Google

are four times ſhorter than the leaves and ſtem-claſping: flowers ſolitary, or very rarely two, ſpringing from the divarications of the branches: corolla white, rather larger than the calyx: floſcules in the diſk numerous, funnel-ſhaped, five-toothed, with the cylinder of anthers violet-coloured.

6. Stature of Sigeſbeckia. Leaves petioled, acutely ſerrate, ſomewhat rugged. Branches oppoſite. Terminating peduncle ſhorter than the leaves, two-flowered: axillary peduncles two on each ſide, two-flowered with another leaflet oppoſite to the pedicel. Flowers yellow. Seeds gibbous, three-ſided, awnleſs. Allied to Lavenia [d]; and perhaps not properly of this genus.

Native of the Eaſt Indies.

7. Seeds almoſt awnleſs, crowned only with a very ſhort four-toothed margin. Calyx five-toothed [e].

Herb ſeemingly procumbent. Leaves ſubſeſſile or ending in the petioles, rugged, three-nerved, the nerves ſpringing within the baſe, quite entire or having only one or two ſerratures at the ſides. Peduncle axillary, naked, very long. Common calyx ſingle, compoſed of ten lanceolate bluntiſh erect leaflets, the five outer wider and ſomewhat longer, all permanent. Corollets of the ray ten, cloven at the tip. Germ oblong, widiſh, crowned with a permanent bell-ſhaped calycle, a cloven ſtyle, and revolute ſtigmas [f].

Stem herbaceous, annual, a foot high, nearly erect, ſmooth, whitiſh. Leaves quite entire, ſmooth. Flowers yellow, terminating, ſolitary, on a very long peduncle. Calyx hemiſpherical, ſingle. Ray ten-flowered. Seeds with a ſhort, awned crown. Receptacle convex; with chaffs as long as the tube of the florets [g].

Native of the Eaſt Indies, and China near Canton.

8. Root annual. Stem herbaceous, branched, a foot high, round, even. Leaves ſeſſile, moſtly terminating, cuneate-ovate, acuminate, nerved, hiſpid. Flowers ſeſſile in the axils of the terminating leaves, two or three together. Calyx ſingle, of four ſcales, two of which are longer, lanceolate, hairy. Hermaphrodite florets five. Female florets four or five, ſhort, blunt, emarginate. Seeds of the diſk black, with two long awns; of the ray wider, toothletted at the edge, and membranaceous, awnleſs at the tip [h].

Gærtner, who ſeparates this from the Verbeſinas, deſcribes the ſeeds as difform: two exterior larger, ovate, flat, ſmooth, of a livid bay colour, girt with a membranaceous toothed white rim; many interior, wedge-oblong, compreſſed, rugged with indiſtinct dots or tubercles, without any rim. Both have a two-awned crown: in the outer ſeeds, the awns are ſomewhat membranaceous, flexile, innocuous; in the inner awl-ſhaped, pungent, diverging, nearly equal to the ſeed in length. Receptacle narrow, flat, within the interior calyx.

According to Gærtner, this plant cannot be aſſociated with the Verbeſinas, becauſe the receptacle is manifeſtly naked, the ray two-flowered exterior, and the ſeeds clearly difform. The calyx alſo is double; the outer two-leaved, the leaflets ovate acute oppoſite equal, containing each a ſingle female floret; the inner eight-leaved in a ſingle row. The petal of the outer female florets entire or ſlightly emarginate.]

Miller ſays it is more than three feet high, the leaves near two inches long, and an inch broad; the flowers yellow, appearing in july, and ſucceeded by others till the froſt ſtops them.

[Native of the Weſt Indies. Cultivated in 1732 by James Sherard, M.D [i].]

9. This riſes with a ſhrubby ſtalk ſeven or eight feet high. Leaves deeply ſerrate and cut ſomewhat like thoſe of the Ilex or Evergreen Oak. The flowers are yellow, produced from the ſide of the ſtalks, and appear in july. Native of the Weſt Indies.

[Linneus remarks, that the ſeeds are wide, as in Coreopſis.—Cultivated by Mr. Miller, in 1768.

10. Stem fifteen feet high, and the thickneſs of a thumb at the lower part, ſmooth, green, and viſcid: it is filled without interruption, by a white inodorous pith as in a ruſh: it is ſimple, or at leaſt but very ſlightly divided at top; and the whole ſtem is aphyllous, the leaves occupying only the upper part and branchlets: they are alternate, foot-ſtalked, and the largeſt are about a foot and a half long; they are villoſe and pinnatifid, with diſtant oblong lobes: from the boſoms of the upper leaves ſpring round whitiſh-villoſe peduncles, bearing at their tips the flowers, which are ſlightly foot-ſtalked, and cloſely heaped together, forming a kind of panicle: the corollets are white and the anthers black [k]. Native of the Weſt Indies. Cultivated by Mr. Miller in 1758 [l].

11. Root annual. Stem herbaceous, procumbent and creeping, branched, ſtriated, ſmooth. Branchlets alternate. Leaves alternate: the upper ones three-parted; leaflets wedge-ſhaped, toothed, blunt; the lower ones entire or ſubtrifid, toothed, ovate, blunt, ſmooth, glaucous beneath. Petioles decurrent, embracing, the length of the leaves, ſmooth. Peduncles terminating, one-flowered. Flowers ſmall, yellow. Common calyx double or calycled: outer of five linear ſcales; inner alſo of five, which are larger, membranaceous, whitiſh. The four or five middle florets of the diſk are five-toothed; the reſt, nearer to the ray, ſmaller and four-toothed. Germ compreſſed: ſtyle cloven: ſtigmas ſlender, reflexed. Female corollets of the ray two-toothed, ſpreading: ſtigma bifid. Fruiting calyx more ſpreading. Inner ſeeds of the diſk oblong, compreſſed, with a membranaceous ſerrate margin; outer round, ſtriated, obtuſe, toothed, having a point in the middle. Seeds of the female florets compreſſed, minute; but commonly wanting. Seed-crown none. Chaffs linear: but none in the middle.

Native of the Weſt Indies, in moiſt paſtures.

The genus of this plant is difficult to determine: for having no ſeed-crown it is not properly a ſpecies either of Verbeſina or Bidens, and ſhould rather be referred to Anthemis, but the habit is different [m]. Mr. Miller cultivated it in 1768.

Loureiro has a ſpecies, which he names Verbeſina ſpicata, and ſays that it agrees with the mutica in having no ſeed-crown, but that in the calyx and corolla it agrees perfectly with this genus, whereas the mutica does not.

He characterizes it as having palmate-gaſhed leaves which are ſerrate, and the flowers in terminating ſpikes: and deſcribes the ſtem as herbaceous but perennial, four feet high, nearly upright, ſometimes creeping, branched, ſtriated, of a duſky red colour: the lower leaves palmate-gaſhed, the upper ovate-lanceolate, all ſerrate, beneath tomentoſe, duſky green, odorous, juicy, alternate, on long red petioles. Flowers very white and ſmall, in linear heaped long erect terminating ſpikes: leaflets of the calyx awl-ſhaped, erect, in a double row: florets of the diſk ſhort and many; of the ray about five, verging to one ſide, the petal not longer than the calyx. Receptacle with very few chaffs. Seeds turbinate, bluntly four-cornered, ſhort without any crown.

Native of China and Cochinchina, and cultivated in thoſe countries, where it is brought to the table with other ſalad-herbs.

12. Stems proſtrate, half a foot long, ſomewhat branched, herbaceous. Leaves alternate, petioled, reſembling thoſe of Abrotanum, naked. Flowers ſubſolitary, on ſhort peduncles. Calyx oblong, cylindrical, containing five or ſix florets, leaflets as many, elliptic, awnleſs, ſcarioſe at the edge. Corollas four-cleft, except one female, which is ligulate and ſeparate from the others: chaff lanceolate, ſmooth, ſhining. Seeds oblong, compreſſed, two-awned. It is an eſculent plant, with the ſmell and taſte of Fennel. Native of the Eaſt Indies, where it was found by Koenig [n].]

PROPAGATION AND CULTURE.

Sow the ſeeds upon a moderate hot-bed in the ſpring, and when the plants are fit to remove, tranſplant them on to a freſh hot-bed to bring them forward; ſhading them till they have taken new root, and then treating them in the ſame way as other tender annual plants, taking care not to draw them up too weak. In june take them up with balls of earth, and plant them in a warm border, where they may be ſhaded

DESCRIPTIONS, &c.

1. Root perennial. Stem four feet high, rough-haired. Leaves ſix or ſeven in whorls, twice as wide as thoſe of V. virginica. Peduncles terminating ſolitary; the lateral ones with two oppoſite oval leaflets. Calyxes five-cleft. Corollets blue, with an oblong tube, and ſmall acute border. Stamens and piſtil twice as long as the Corolla [o].

Gmelin ſays, that the leaves vary from five to nine in a whorl, but that ſix is the moſt common number; and that the fruit is like that of Salicaria.

Native of Siberia. Introduced in 1779, by Chevalier Thunberg. It flowers in july and auguſt [p].]

2. Stems erect, four or five feet high, having four or five lanceolate leaves in whorls at each joint, ſerrate and ending in acute points. The ſtems are terminated by long ſlender ſpikes of white flowers, which appear

[o] Lin. ſpec. and ſyſt. [p] Hort. kew.

Digitized by Google

late in july. [It varies with bluſh-coloured flowers. Native of Virginia (and Japan.) Cultivated in 1714, by the Dutcheſs of Beaufort [q].]

3. Root perennial, ſending out many offsets. Lower leaves two inches long, and half an inch broad, pale green and hairy. Stems a foot high, with very narrow lanceolate leaves, placed oppoſite, and having a few ſlight ſerratures on their edges. Stems terminated by long ſpikes of blue flowers, which appear in june and july. There is a variety of this alſo with a fleſh-coloured flower.

[Native of Siberia and Germany. Cultivated by Mr. Miller in 1731 [r].]

4. Stalks not ſo long as thoſe of the preceding. Leaves by fours and threes round the ſtalk, on longer foot-ſtalks; they are broader at the baſe, run out into long acute points, are unequally ſerrate, and of a bright green colour. The flowers are of a bright blue, and appear in july.

[It varies, like the preceding and following ſpecies, with leaves oppoſite, in threes or in fours; alſo with blue, blueiſh, fleſh-coloured and white flowers.

Roth deſcribes the calyx as unequal, with two of the leaflets linear and longer, the two others ſhorter, wider and bifid. Willdenow remarked them to be always undivided; he doubts therefore whether Roth's plant be the ſame with this [s].

Native of the ſea coaſts of Europe. Cultivated, as we learn from Lobel, (adv. 145.) in 1570, by Mr. Hugh Morgan [t].

Ehrhart has a variety with broader leaves [u].]

5. Lower leaves two inches long, and an inch broad in the middle, drawing to a point at each end, ſerrate, and of a lucid green colour. Stems a foot and a half high, with leaves of the ſame ſhape but ſmaller, and placed oppoſite; they are terminated by long ſpikes of blue flowers which appear in june.

[Native of Germany, Auſtria, and Ruſſia. Cultivated in 1731, by Mr. Miller [x].]

6. Stems very white and woolly, about a foot high. Leaves oblong, hoary, two inches and a half long, three quarters of an inch broad, ſeſſile. Flowers deep blue in terminating ſpikes, and from the upper axils. They appear in june and july.

[Native of Ruſſia, (Mr. Miller ſays Ukrain Tartary.) Cultivated by him in 1759 [y]. According to Gmelin, it varies with white flowers.

7. Root perennial. Stems a ſpan high, aſcending, ſimple, round, leafy, ſomewhat woody, pubeſcent. Leaves moſtly blunt, but ſometimes ſharpiſh, hairy. Spike erect, many-flowered. Corolla deep blue, with the orifice of the tube bearded [z].

Dr. Withering remarks, that the leaves are narrower in proportion to their length, and more pointed than in the hybrida; that the ſtamens are much longer than the corolla; and that the anthers, as well as that, are blue.

In gardens it becomes much more luxuriant.] There the ſtalks riſe a foot and half high, but never branch; the lower leaves are an inch and half long, and three quarters of an inch broad. Mr. Miller aſſerts that the upper ones are alternate.

[It varies with linear almoſt entire leaves: with fleſh-coloured and white flowers: and according to Haller, with ſeveral ſpikes, which is V. major anguſtifolia of Cluſ. pann. 617. 619. and Bauh. hiſt. 3. 284.

Native of Europe and Siberia; in dry calcareous paſtures; flowering from july to ſeptember. With us not common, but where it is found, it is abundant. Ray obſerved it in ſeveral cloſes adjoining to Newmarket heath beyond Botteſham, and in a cloſe near the beacon. Mr. Relhan—among the furze near Hare Park, about Horſeheath hall, and on the walls of St. John's College, Cambridge. Mr. Woodward—on Cavenham heath, near Bury, in Suffolk; and near Penny bridge, Lancaſhire. Dr. Withering—about Penzance in Cornwall. Its bright blue flowers agreeably enliven the barren places where it generally grows.

The figure in Flora Danica is ſo incorrect, that it is difficult to decide whether this, or one of the ſpecies nearly allied to it was intended [a].

[q] Idem. [r] Idem. [s] Willdenow. [t] Hort. kew. [u] Willdenow. [x] Hort. kew. [y] Idem. [z] Smith brit. [a] Engl. bot.

8. The difference between this and the preceding is not eaſily defined, and yet they ſeem to be diſtinct, though ſome have thought otherwiſe. It is twice as large, with rougher ſtem and leaves; the latter are more ſtrongly ſerrate or notched, of a much broader elliptical form, and of a more graſſy green. The winged foot-ſtalk is common to both. The ſtem of this generally produces three ſpikes, when luxuriant. It always grows erect. The root is creeping and perennial. The flowers appear in july and auguſt [b].

Willdenow remarks, that the leaves are ovate, acuminate, bluntiſh, attenuated at the baſe into the petiole, pubeſcent but yet green. He refers the V. mas recta latifolia ſpica cærulea of Barr. ic. 682. to this ſpecies; but informs us that all the German authors have taken a variety of the ſpicata for the hybrida.

Mr. Lhwyd firſt found it in Ray's time on the ſide of a hill in Montgomeryſhire called Craig Wreidhin. Mr. Bingley has ſince gathered it near Cartmel Wells, Lancaſhire, on Humphrey head, a ſteep rock jutting into the ſea, where Mr. Crow and Mr. Woodward obſerved it eighteen years before. Dr. Withering ſays that Mr. Hall ſaw it growing plentifully there. On comparing my wild ſpecimen of this plant from Wales, with that of the ſpicata from Newmarket heath, I find it to be ſtouter but not ſo tall; the radical leaves are truly elliptic and extremely blunt, certainly not acuminate, only the upper ſtem-leaves are acute. The petioles of the radical leaves can ſcarcely be called winged in either ſpecies. My Welſh ſpecimen has the ſtems rather aſcending than erect, and there is no ſign of more than one ſpike at the end of each ſtem, of which there are two fertile and two barren on my ſpecimen.

Mr. Miller's deſcription is from a very luxuriant garden plant.

9. Root perennial. Stems diffuſed erect. Leaves oppoſite, ſomewhat crowded, having commonly three linear elongated teeth on each ſide, and ſmooth. Raceme the length of the ſtem. Calyxes equal. Flowers blue. Style capillary, permanent. Capſules oval. Native of Siberia, where it was found by Laxmann [c]. Introduced in 1776, by Chevalier Murray. It flowers in july [d].

It varies with filiform aggregate leaves [e].

10. Native of Siberia. Introduced in 1780, by William Pitcairn, M.D. It flowers in june and july [f].

11. This differs from the preceding, in having the ſpikes never ſolitary but aggregate, the flowers bigger, the leaves an inch long, lanceolate wedge-ſhaped at the baſe, with lanceolate ſegments [g].

Native of Siberia. Introduced in 1779, by Meſſ. Kennedy and Lee. It flowers in july and auguſt [h].

12. 13. Natives of New Zealand [i].

14. Stem ſhrubby. Branches round, ſmooth, jointed, covered with a brown bark. Leaves ſeſſile, four inches long, even, without veins or nerves, flat at the edge, attenuated outwards. Racemes from the uppermoſt axils, oppoſite, length of the leaves: pedicels alternate, copious, ſomewhat villoſe. Bracte linear, minute, obtuſe, ſubciliate. Calyx-leaves ſmall, lanceolate, acuminate. Tube of the corolla twice as long as the calyx: ſegments of the border oblong, obtuſe. Capſules ovate, acute, three times as long as the calyx. The leaves are wider at the baſe than in the ſpecies next following. Native of New Zealand.

15. Branches round, ſmooth, covered with a brown bark, jointed, marked with rings after the leaves are fallen, the thickneſs of a gooſe quill. Leaves oppoſite, four or five inches long, ſeſſile, attenuated to both ends, ſomewhat waved, ſmooth and very even, veinleſs. Racemes axillary, oppoſite, longer than the leaf. Peduncles round, very ſmooth, an inch and half long. Pedicels capillary, very abundant, ſeveral from the ſame point; when fruiting bent back. Bractes at the baſe of the pedicels, awl-ſhaped. Calyx four-leaved: leaves ſhorter than the corolla, equal, awl-ſhaped. Tube of the corolla twice as long as the calyx: ſegments of the border lanceolate, acute. Capſule oblong, acute, twice as long as the calyx [k]. Native of New Zealand [l].

[b] Idem. [c] Lin. mant. and ſyſt. [d] Hort. kew. [e] Willdenow. [f] Hort. kew. [g] Willdenow. [h] Hort. kew. [i] Forſter. [k] Vahl. [l] Forſter.

16. Branches round, ſmooth. Leaves ſeſſile, approximating, an inch long, rigid, even, mucronate with a plaited tip. Racemes from the uppermoſt axils, oppoſite, an inch and half long. Peduncle round ſhort. Pedicels oppoſite, ſhort. Bracte minute at the baſe of each. Calyx four-leaved: leaves oblong, obtuſe, ſmooth, ſubciliate. Segments of the corolla obtuſe. Style longer than the corolla. Capſules oval, twice as long as the calyx. Native of New Zealand [m].

17. Root perennial, fibrous. Stems widely diffuſed, from three to ſeven inches or a foot in length, round, hirſute, ſtiffiſh, creeping. Leaves hirſute with ſhort ſpreading hairs, that appear when magnified, finely jointed, and rugged, ſerrate, about an inch in length, the lower ones narrowed at the baſe, the upper ones oblong or oval, obtuſe, ſeſſile or nearly ſo, the lower ones ſomewhat ſmaller and petioled. Spikes axillary, ſolitary, on long peduncles, many-flowered, hairy; ſome ſo nearly terminating, that at firſt view they ſeem to be ſo, but upon more accurate examination we find one or more pairs of leaves beyond them. Under each flower is a linear bracte, obtuſe, downy, longer than the pedicel, but ſcarcely the length of the calyx, and upright. Calyx deeply divided into four ſegments, beſet with rough glandular hairs; ſegments ovate-lanceolate and nearly equal. Corolla tube half as long as the calyx, white, border pale purple or faint violet, with deeper veins or ſtreaks; the ſegments ovate, obtuſe, three larger and nearly equal, the fourth half the width of the others. Anthers blueiſh with a white pollen. Germ ſomewhat ovate, obtuſe, flattened, clammy, grooved on each ſide, ſurrounded at its baſe by a gland. Style a little thickened towards the top, violet. Stigma truncate [n]. Capſule ſmall, a little longer than the calyx, obcordate, with a groove on each ſide, compreſſed, ſomewhat villoſe, opening at top tranſverſely: partition very narrow, contrary to the valves. Seeds ſix or eight in each cell, elliptic, compreſſed, ſmooth, yellow or pale brown [o].

Native of Europe, on dry ſandy paſtures, and heaths. In England not uncommon; flowering from may or june to auguſt or later. It varies in the colour of the flowers, pale blue, pale red, and white; but what is much more remarkable, it has been found abroad with double flowers.

The leaves have a weak not diſagreeable ſmell, which is diſſipated in drying; they give it over in diſtillation with water, but without yielding any ſeparable oil. They are bitteriſh and roughiſh to the taſte. An extract made from them by rectified ſpirit is moderately bitter and aſtringent.

It has been much recommended, eſpecially in Germany and Sweden, as a ſubſtitute for Tea, than which it is more aſtringent and leſs grateful. As a medicine it has had a conſiderable ſhare of fame, particularly in diſorders of the lungs, as coughs, aſthmas, conſumptions, &c. in which it was ſaid not only to prove expectorant, but to heal internal ulcers. If we may judge of its utility by its ſenſible qualities, it is only to be recognized as an aſtringent; and even as ſuch it is entirely diſregarded in England by medical practitioners [p]. Mr. Miller ſays, it is one of the vulnerary herbs which are imported from Switzerland. It is very common in that country, and Haller ſpeaks well of its effects. In France it is ſtill called Thé de l'Europe.—"We do call theſe plants in Engliſh, ſays Gerarde, Paul's Betonie or Speedwell: in Welſh it is called Fluellen, and the Welſh people attribute great virtues to the ſame."

18. Root perennial, creeping. Stem round, ſmooth, procumbent, creeping very far. Leaves roundiſh or obovate, firm, rigid, totally different in ſubſtance from thoſe of the officinalis, ſmooth, ſhining, crenate, paler on the under ſide. Spikes oval, denſe, on long footſtalks Flowers very numerous, violet-coloured, of a different figure from thoſe of V. officinalis [q].

Villars ſays it is eaſy to know this ſpecies by its creeping hard woody ſtems, which run on the ſurface in the moiſt turf of the Alps. Its blue flowers form tufted ſpikes thickly ſet an inch in length. The diviſions of the corolla are often rolled obliquely.

It is plentiful on the Alps of Switzerland, France and Italy: alſo on the Pyrenees. Dr. Smith ſays that he has frequently compared it, in its native ſoil, with the common V. officinalis growing in the ſame place; and that it is moſt certainly a diſtinct ſpecies. He has never ſeen the variety with hairy leaves and ſtem mentioned by Villars, under the name of V. Tournefortii.

19. This is a buſhy ſhrub about two feet high. Stem upright, round, very much branched. Branchlets alternate, ſpreading, round or indiſtinctly quadrangular, cloſely leafed on every ſide, having a pubeſcent line on each ſide running down from the oppoſitions of the leaves; which ſpread very much, are ſcarce an inch long, acute, coriaceous, ſmooth and even, one-nerved, paler underneath, evergreen, border cartilaginous, on very ſhort concave ſmooth petioles, gibbous at the baſe on the outſide. The regular growth of theſe leaves, decuſſated or croſſwiſe, diſtinguiſhes this ſpecies immediately. Racemes ſingle, ſhort, few-flowered, towards the end of the branches, not terminating, but juſt below the top. Pedicels alternate, ſhort, quadrangular, one-flowered. Bractes ſolitary, lanceolate, obtuſe, keeled, ſubciliate. Calyx deeply four-parted; ſegments ovate, acute. Corolla milk-white, with the diviſions nearly equal, ſpreading, and the orifice beardleſs. Filaments ſhorter than the corolla, divaricating, white. Anthers cordate, purple. Germ ovate-oblong, ſmooth, ſcored with a line on each ſide, and having four nectareous glands at the baſe. Style awl-ſhaped, declined, length of the ſtamens. Stigma acute [r].

Dr. Smith remarks, that the flowers having no ſcent, and little beauty, this ſhrub would not be worth cultivating, were it not for the amenity, abundance and ſingularity of the perennial leaves. Mr. Curtis on the other hand ſays it is entitled to our admiration, on account of the moſt delicious fragrance of the bloſſoms, ſimilar to that of the Olea fragrans. He obſerves that the corolla is ſometimes divided into five ſegments; and there being a greater equality in theſe than is uſually found in the corolla of this genus; the ſeed-veſſel alſo differing in its form, being longer, more oval, and ſcarcely emarginate, he is induced to think that this plant has more affinity with Olea, one ſpecies of which it reſembles in fragrance.

Juſſieu and Gmelin have ranged it in a new genus named Hebe. But Dr. Smith aſſerts that it differs in no reſpect from Veronica, except in its arboreſcent habit, and in having the fruit compreſſed the contrary way to what it is in the other ſpecies. The flower correſponds in almoſt all reſpects.

Native of Falkland Iſlands, whence John Fothergill, M.D. received it in 1776 [s]. It flowers about the middle of june, and continues during the ſummer.

20. Stem not longer than a finger, very ſlender, ſomewhat villoſe, leafleſs, few-flowered. Leaves at the baſe four or five, ovate, ſoft, ſubcrenate. Corolla tinged inelegantly with blue. Seeds in each cell as far as ten, yellow, compreſſed, rounded [t].

Villars remarks that it varies conſiderably; commonly appearing as a ſingle tuft of villoſe rounded leaves; but ſometimes with ſeveral ſtems creeping to right and left, forming tufts here and there, and bearing only two or three flowers on each.

Haller deſcribes it in this latter ſtate, and ſays that there are not more than ſeven flowers in a raceme; and that the leaves are roundiſh, crenate, not hard, and hirſute with longiſh hairs.—Theſe hairs are characteriſtic of the ſpecies, being jointed like a Conferva.

Native of the Alps of the ſouthern part of Europe, and the north of Aſia.—Introduced in 1775, by the Doctors Pitcairn and Fothergill. It flowers in may.

β. Is only a variety of this, differing in the greater ſize of all its parts. The circumſtances of the hairs being articulated like a Conferva, and the leaves being ſerrate, are common to both [u].

21. Leaves obtuſe, crenate, commonly three pairs on the ſtem. Calyx-leaves very hirſute, glandular-viſcid at the tip [x].

The leaves are like thoſe of the Daiſy, whence its

[m] Vahl. [n] Curtis, Withering, Smith. [o] Gærtner. [p] Woodville. [q] Smith in Linn. tranſ. [r] Smith ſpicil. [s] Hort. kew. [t] Scopoli. [u] Smith in Linn. tranſ. [x] Linn. mant.

Digitized by Google

trivial name. Stem ſtraight, four or ſix inches high, villoſe, hard, having leaves at its baſe, two or three pairs, beſides others ſmaller, terminated by a cloſe ſpike of ſmall reddiſh dark flowers. Capſules villoſe, elongated[y].

Native of the Alps of Switzerland, eſpecially about Aigle, Piedmont, Dauphiné, Sileſia, and the Pyrenees. —Introduced in 1775, by the Doctors Pitcairn and Fothergill. It flowers in june and july[z].

22. Root perennial. Radical leaves oppoſite, lanceolate, acute, irregularly crenate, marked with three nerves, perfectly ſmooth, pale, and ſomewhat cartilaginous in the margin, very much reſembling thoſe of Gentiana acaulis, whence the trivial name. Thoſe on the ſtem are ſtrikingly different, obtuſe and hairy. Stem aſcending, ſmooth below, hairy in the upper part. Corymb ſomewhat ſpiked, conſiſting of many flowers. Footſtalks hairy. Calyx hairy, quadrifid, equal. Corolla large, beautiful, of a deep blue. Anthers heart-ſhaped, large.

Gathered by Tournefort in Cappadocia. By Buxbaum in Armenia. Dr. John Sibthorp alſo found it in his tour to the eaſt[a].

23. Root perennial. Stems ſeveral, quite ſimple, a hand high or a little more, hiſpid with cloſe-preſſed hairs, round or bluntly four-cornered. Lower leaves orbicular, ſeſſile, crenate; the middle ſtem-leaves a little longer, acuminate, and more acutely crenate; the two or three uppermoſt alternate, half-embracing. Raceme looſe, terminating, containing about fifteen flowers, with a very ſmall ligulate bracte to each[b]. Native of the Pyrenees and Monte Baldo.

β. V. pumila of Allione ſeems to differ only in ſize. Native of the Piedmont alps.

24. In ſtrong woody roots, and ſtems branching and intricate at their baſe, this agrees with the ſaxatilis, but the flowering-branches are perfectly upright, ſix inches or more in height, each bearing a ſpike rather than a corymb, compoſed of a conſiderable number of fleſh-coloured flowers, (never blue,) on pedicels ſcarcely exceeding the bractes in length. The leaves alſo are rather paler, much more numerous, oblong, a little downy on their edges and veins: they are ſometimes quite entire, ſometimes crenate or ſerrate. The calyx and capſule agree much with thoſe of V. ſaxatilis, and the pedicels are lengthened out as the fruit ripens, but never in ſo great a degree as in that ſpecies.

In both theſe Speedwells the flowering branches are merely annual, though the ſtem below is woody and truly perennial, ſo that the latter ought rather to be eſteemed the naked crown of the root.

Native of the mountains of Switzerland, Auſtria, Piedmont, Dauphiné, and of the Pyrenees. Firſt found in Cruachan Argyleſhire in Scotland, by the Rev. Dr. Walker, and communicated to Dr. Smith in 1782. Alſo on Ben Lawers with the ſaxatilis, by Mr. Brown; both flowering at the ſame ſeaſon.

25. The roots run deep into fiſſures of rocks, and the woody branching entangled ſtems form ſmall tufts, whence the ſimple leafy round downy flowering-branches, three or four inches long, ſpread in every direction. Leaves oppoſite, ſmall, elliptic or oblong, blunt, always entire at their baſe and extremity, but often ſerrate in ſome degree about their middle: they are a little thick or fleſhy, ſmooth, of a dull darkiſh green, turning black when dry. From three to ſix large handſome dark-blue flowers grow in a ſhort terminating corymb, the pedicels of which are twice or thrice as long as their correſponding bractes. Calyx in four nearly equal blunt downy ſegments. Orifice of the corolla elegantly tinged with red. Capſule longer than the calyx, ovate, downy, ſplitting as it ripens into four lanceolate valves, ſo that the fruit differs much from the heart-ſhaped form of our common ſpecies[c].

It differs from the preceding in having broader leaves, more diffuſed ſtems, larger flowers of a blue colour; but eſpecially by its peduncles being longer and fewer, in a corymb, never in a ſpike[d].

Native of Switzerland, Auſtria, Denmark, Norway and Scotland. Found on Ben Lawers by Mr. G. Donn, Mr. J. Mackay, and Mr. Dickſon.

This beautiful little plant has long been known in the more curious Engliſh gardens by the name of V. fruticuloſa, with which many botaniſts, (even Linneus, Haller, and Jacquin originally,) have confounded it[e]. It was cultivated by Mr. Miller in 1748[f], under the name of fruticuloſa.

According to Willdenow V. Nummularia of Gouan; and V. pygmæa of Schrank, are varieties of this ſpecies.

26. Root perennial, of long ſimple fibres. Stems branched and procumbent at the baſe, whence they throw out roots, then obliquely upright, three or four inches high, leafy, round, ſimple, ſmooth or hairy. Leaves oppoſite, on ſhort petioles, rather obtuſe, often entire but generally with a few diſperſed notches, dark green, thin, poliſhed. Flowers ſmall in a ſhort denſe blunt ſpike or corymb, afterwards lengthened out into a raceme; the lowermoſt peduncles longer. Calyx in four rather unequal bluntiſh hairy and ciliate ſegments. All the hairs are finely jointed. Corolla bright blue, with a white tube. Capſule elliptic, compreſſed, emarginate, hairy, tipped with the ſhort permanent ſtyle[g].

Native of the mountains of Europe. Diſcovered by Mr. Dickſon in the highlands of Scotland, about Garway-moor, and on Ben Nevis in 1786, and not before in this iſland. Mr. J. Mackay has ſince found it on the mountains of Badenock. It flowers in july and auguſt. What has been taken for it before, was either a large variety of V. ſerpyllifolia, or V. fruticuloſa.

Mr. Dickſon ſuppoſed the V. alpina of Lightfoot to be a new ſpecies, which he named humifuſa, but Dr. Smith makes it a variety of the ſerpyllifolia; conſequently the deſcription in the Flora Scotica, compiled from Linneus's Flora Lapponica, is there miſapplied, and belongs to the ſpecies here before us[h].

27. Willdenow has diſtinguiſhed this from the preceding by his dried ſpecimens, it appearing to differ from that in its habit. All the leaves are oppoſite, quite entire, more rigid and very blunt. Schmidt (in fl. bohem. 1. n. 16.) confounds it with the preceding, but it differs from it in having the leaves blunt and quite entire, and the calyxes very hairy. The leaves in both are ciliate at the edge, and the hairs are jointed like a Conferva[i].

Krocker deſcribes the lower leaves on very ſhort petioles, the upper ones ſeſſile and ſmaller, all ovate, quite entire or indiſtinctly toothed, by no means ſmooth but truly villoſe. Corymb very ſhort, of five or ſix flowers on very ſhort pedicels, with a green lanceolate very narrow bracte to each. Calyx hairy. Corolla ſmall, blue or white. Capſule obtuſe, leſs compreſſed, villoſe, large in proportion to the plant, roundiſh, cordate. Native of the Palatinate, Bohemia and Sileſia.

28. Roots perennial, fibrous; and the proſtrate ſtems throw out numerous radicles by which the plant is much increaſed. The flowering-branches are moſtly erect, bearing a few pairs of oppoſite, roundiſh, ſlightly crenate, three-ribbed leaves, on ſhortiſh footſtalks. Each branch terminates in a lax ſpike or raceme of ſmall pale blue, ſometimes fleſh-coloured flowers, accompanied by elliptical ſeſſile bractes. Segments of the calyx equal, obovate, blunt, ſcarcely pubeſcent. Corolla, however pale, always marked with dark-blue ſtreaks. Capſule obcordate, deeply divided, about as long as the ſtyle. In wet places the whole herb is very ſmooth and ſhining, rather fleſhy; when it occurs in very dry ſpots, it becomes all over downy: indeed the peduncles and bractes are frequently liable to this alteration.

Native of Europe, Siberia, Barbary and North America. Common with us in paſtures which are rather moiſt; ſometimes in the ſhady parts of cultivated grounds, flowering in the early part of ſummer[k].

Mr. Curtis informs us that he has counted ſixty ſeeds in one capſule; they are of a yelloviſh brown colour, and nearly of an ovate form.

β. From a compariſon of ſpecimens of Mr. Dickſon's V. humifuſa, found in the mountainous rills of

Scotland, Dr. Smith has ventured to make it a variety of this ſpecies, which is liable to many variations with reſpect to the poſition of its ſtems and form of its leaves. —The ſtem of the humifuſa is proſtrate, and the raceme ſhorter[l]: having few flowers crowded together on ſhort pedicels, of a pleaſant blue. Lower leaves petioled, oppoſite, often by threes or fours: upper ones moſtly ſeſſile and alternate[m].

29. This ſeems to differ little from the preceding except in having the upper part of the ſtem and the calyxes villoſe; but it is entirely different from Gouan's V. nummularifolia, which ſeems to be a variety of V. fruticuloſa[n].—It is given above as a variety of ſaxatilis.

Native of the Piedmont Alps, and the Pyrenees.

30. Roots perennial, of long ſimple fibres. Stems procumbent or floating, taking root from their joints, branched, round, leafy, ſmooth and ſhining, as is every other part of the herb. Leaves on ſhort petioles, blunt, ſlightly ſerrate, of a bright green, ſomewhat fleſhy. Cluſters axillary, oppoſite, erect, longer than the leaves, compoſed of numerous blue flowers, in perfection about june or july. Bractes linear-lanceolate, ſhorter than the pedicels. Segments of the calyx ovate, acute, ſhorter than the corolla. Capſule cloven, almoſt twin[o].

Withering remarks that there are glands at the ſerratures of the leaves; and that the germ ſits on a thick yellowiſh-green glandular ſubſtance.

Native of Europe, Siberia and Barbary. Common in ditches and limpid brooks, moſt commonly the companion of Water Creſſes; with which it is gathered for medical purpoſes, and both together with Scurvygraſs enter into that nauſeous compoſition called Spring-juices, ſuppoſed to be a powerful antiſcorbutic[p].

The leaves are mild and ſucculent, and may be eaten with water-creſſes as a ſalad in the ſpring[q]. They have a bitteriſh ſubaſtringent taſte, but manifeſt little or no acrimony, nor any peculiar odour. To derive any advantage from it the juice muſt be uſed in large quantities, or the freſh plants eaten as food[r].

31. Root perennial, creeping. The whole herb much agreeing in habit with the preceding, except that the ſtem is erect, and leaves lanceolate, acute, and longer than in that ſpecies. The cluſters are alſo longer, ſharper, compoſed of more numerous (thirty to forty or more) and ſmaller flowers. Every part of the plant is ſmooth. Corolla of a pale dull blue, occationally fleſh-coloured, with darker veins. Capſules ſmall, roundiſh, ſlightly notched. Seeds very ſmall and numerous.

No notice is taken of this plant in a medical or œconomical view. Its qualities are probably akin to thoſe of the broad-leaved Brooklime, to which it is nearly allied in botanical characters, though unqueſtionably a diſtinct ſpecies.

Native of the four quarters of the world: moſt parts of Europe, Siberia, Barbary and North America. Very common in our ditches, and muddy watery places, flowering in july, and like other aquatics which are tenacious of life or eaſily propagated, it is often found out of the water on the neighbouring banks, merely diminiſhed in luxuriance[s]. It is ſingular that Linneus and Curtis conſider this as annual.

32. Root ſlender perennial, throwing out creeping runners, and a few weak, ſpreading, ſimple ſtems, ſix or eight inches long, clothed with oppoſite linear or linear-lanceolate leaves, which are generally but ſlightly toothed, ſometimes ſerrate, and ſometimes entire. The racemes or cluſters are always alternate, ſingle, lax, divaricating, varying in length, and conſiſting of a few pale fleſh-coloured or whitiſh purple-veined, rather elegant flowers, the ſlender pedicels of which are bent backwards after the corolla fades, and then the ripening capſules, which are brown, and larger than in V. Anagallis, become conſpicuous, and have given riſe to the name ſcutellata, as reſembling ſmall ſhields. They are deeply emarginate.

Though for the moſt part ſmooth, yet it has been found in a downy ſtate on St. Faith Newton bogs near Norwich, and in other places[t].

Native of many parts of Europe, and Barbary, in bogs and on the edges of ponds on heaths and moors; flowering from june to ſeptember. It is not uncommon with us in ſuch ſituations, eſpecially where the ſoil is ſandy, though much leſs ſo than the other Brooklimes. Cambridgeſhire, on the Hill of health, Barnwell, by the road to Hiſton, Teverſham moor, pits near Gamlingay bogs; Fenlake, Stevington and Ampthill, Bedfordſhire; Peat-bogs on Bullington Green, and Otmore in Oxfordſhire. Boggy meadows near Bungay. Broadmore near Hales Owen. Ditches about Tamworth. On Poole and Canford heaths, in Purbeck, &c. Dorſetſhire; obſerved by the late Dr. Pulteney, who informs that this elegant ſpecies was firſt noticed in England by How, phyt. brit. 7. On Streatham common, in Surrey, where I obſerved it many years, the plant is ſmooth, and the flowers white. Near London, it is alſo found on Hampſtead heath. Bogs on Harefield common, by Mr. Blackſtone.

33. Racemes denſe, ſtrict, ſubſpiked. Leaves very bluntly ſerrate. The calyxes ſeem to be five-cleft. There is a variety with a double flower[u].

Dr. Smith ſays it ſeems to belong to V. latifolia, but there being no original ſpecimen of it in the Linnean herbarium, he cannot determine the matter with abſolute certainty[x]. Willdenow informs us, that he has always ſeen the latifolia or a larger variety of the proſtrata under this name, and that it muſt therefore remain a dubious plant.

34. This alſo is conjectured by Dr. Smith to belong to the latifolia, and as he informs us, that Linneus eraſed his long deſcription of it from his copy of the Species Plantarum, I have omitted it.

Willdenow ſays that he has a ſpecimen from Bohemia, which is certainly diſtinct from all the other ſpecies. It reſembles the proſtrata in its habit and the form of the corolla, but is different, in having the leaves deeply toothed at the baſe and more ovate, and the ſtem hairy in two rows: it differs from V. Chamædrys in having ſmaller leaves deeply toothed at the baſe, the ſtem proſtrate, the calyxes unequal, the ſegments of the corolla acute and converging.—The ſtem is proſtrate, round, bifariouſly pubeſcent; leaves ovate, the lower petioled, the upper ſeſſile and obtuſe, hairy, bluntly toothed, the lower teeth elongated; racemes axillary in the upper part of the ſtem as in V. proſtrata; bractes lanceolate, quite entire, hairy, longer than the peduncle; peduncles ſhort; calyx four-cleft, with the two outer ſegments bigger. Native of Auſtria and Bohemia.

35. Root perennial. Stems hardiſh, hoary, ſomewhat tomentoſe. Leaves obtuſe, ſubpetioled except the upper ones, from the axils of which proceed long racemes. Calyxes five-cleft, unequal. Flowers bright violet, crowded[y]. Native of Germany, Italy and Switzerland, on hills.—Introduced in 1774, by Chevalier Murray. It flowers in may and june[z].

36. Root perennial. Stems proſtrate, ſuffruticoſe at the baſe, pubeſcent. Leaves like thoſe of Chamædrys; elliptic, oblong, very deeply and equally ſerrate, ſo as to reſemble the teeth of a comb, ſubpetioled, oppoſite, pubeſcent. Flower-ſtalk lateral, a hand in length, having five or ſix ſimilar leaves on it, but alternate and ſeſſile: it is terminated by a corymb elongated into a raceme[a]. Calyx five-cleft[b]. Native of the neighbourhood of Conſtantinople.

37. Root fibrous, perennial. Stems decumbent, weak, hairy all over, leafy. Leaves petioled, ovate, gaſh-ſerrate, thin, ſhining, ſomewhat hairy. Racemes axillary, alternate, lax, few-flowered. Flowers pale blue painted with purple. Capſule orbicular-twin, compreſſed, acutely margined, ciliate[c].

The hairineſs of the ſtem being general, and not confined to two longitudinal lines, is a ſufficient diſtinction of this from V. Chamædrys: to this we may add, that the leaves are petioled, thinner and more ſhining; that the corolla is much ſmaller and leſs beautiful; and that the capſule is thrice as big, more compreſſed and

[l] Smith brit. and engl. bot. [m] Dickſon in Wither. [n] Vahl. [o] Engl. bot. [p] Idem. [q] Withering. [r] Woodville. [s] Engl. bot. [t] Idem.

dilated,

Digitized by Google

dilated, and formed as it were of two orbicular portions joined together inſtead of being heart-ſhaped [d].

Dr. Withering remarks that beſides the leaves being petioled, they are reddiſh underneath, heart-ſhaped but blunt, the ſtem and leaf-ſtalks hairy, the flowers ſmaller purpliſh-ſtreaked.

Mr. Relhan adds, that the capſules not only differ in ſize and form from thoſe of the Chamædrys, but are acutely margined and ciliate, and that the flowers are fewer in the racemes. And Dr. Abbot—that the root is greatly creeping, the leaves deeply notched, the fruitſtalks diſtinct and very long, the flowers paler and fewer than in V. Chamædrys.

Native of Germany, Auſtria, Switzerland, France, Italy and Britain. With us it is not ſo rare as it was formerly ſuppoſed, in ſhady and moiſtiſh woods, particularly on a chalky ſoil: flowering in may and june. It is ſtill found growing copiouſly in Charlton wood, where Sherard firſt diſcovered it. Dr. Goodenough gathered it near Virginia water. In Cambridgeſhire it is ſeen in ſeveral places, as the woody part of the Devil's ditch, on Newmarket heath, in Hall wood, about Linton, and in Gamlingay park. In Bedfordſhire at Everſholt. In Shotover plantations, Stokenchurch and Nettlebed woods. Near Worceſter. At Shortwood, Pucklechurch, Glouceſterſhire. By the river ſide under Hod hill, Dorſetſhire. About Kirkſtal Abbey near Leeds, and in other parts of Yorkſhire common. In the woods at Dunglaſs, near the river, Scotland.

38. Root perennial, fibrous, a little creeping. Stems ſpreading, but ſlightly raiſed from the ground, ſimple, round, hard, waving, leafy, branched, marked longitudinallly, as Linneus well remarks, with a line of long white hairs, very thick ſet together, on each ſide. Leaves oppoſite, ſpreading, deeply and acutely ſerrate, ſtrongly veined, moſt hairy about the margin, the lower ſmaller than the upper ones. Racemes axillary, generally oppoſite, ſimple, upright, long, riſing above the top of the ſtem, their common peduncle hairy in every direction. Flowers as many as twenty in a raceme, on ſlender pedicels, with a lanceolate bracte at the baſe of each; they are large, the corolla bright blue elegantly veined of a deeper blue, pale and ſomewhat fleſh-coloured on the outſide; the orifice is white, as are alſo the baſe and the point of the filaments, the pollen, and the baſe of the ſtyle. The ſtamens are ſpreading, and the ſtyle is ſpontaneouſly directed firſt to one and then to the other. Stigma reddiſh. Germ woolly, flattiſh, and ſurrounded by a nectariferous gland at the baſe. Capſule exactly obcordate, ſmall, a little ſhorter than the calyx, light brown, ſlightly hairy at the edge. Seeds flat, of a yellowiſh-brown colour [e].

Native of Europe and Japan. Few of our wild flowers can vie in elegance and brilliancy with this; and many plants with far leſs beauty are cultivated in our gardens. In may and june every hedge-bottom and graſſy bank is adorned with it. At night, or under the influence of moiſture, the corolla cloſes, but in dry bright weather appears fully expanded, and though each flower is ſhort-lived, there is a copious ſucceſſion [f].

Mr. Curtis remarks, that when growing wild, the leaves are uſually ſeſſile; but when cultivated, theſe become larger, and have footſtalks of a moderate length; thus approaching to V. montana, which it much reſembles. At the end of ſummer a white hairy knob is frequent on this plant; it is the neſt of ſome inſect.

This pretty plant is neither very uſeful nor injurious to the huſbandman. The leaves, according to Dr. Withering, are a better ſubſtitute for tea than thoſe of V. officinalis, being more grateful and leſs aſtringent [g].]

39. This has ſlender branching declining ſtalks, with narrow leaves on them, which are acutely cut on their edges, and are regular on both like the lobes of pinnatifid leaves; they are of a pale green colour, and ſmooth. The flowers are diſpoſed in looſe ſpikes (racemes) on the top and ſides of the ſtalks; they are of a pale blue colour, and appear at the end of april. Native of the Levant.

[d] Engl. bot. and Curt. lond. [e] Engl. bot. and Fl. ruſt.
[f] Engl. bot. [g] Fl. ruſt.

[Cultivated in 1759, by Mr. Miller. It flowers in july and auguſt [h]. It was confounded by Linneus with the auſtriaca.

40. Leaves multipartite, their laciniæ pinnatifid, with the lobes decurrent. Calyx quinquefid, perfectly ſmooth. It appears not to turn black or brown in drying. It is only known by an original ſpecimen from Siberia, its native country, by which it appears to be totally diſtinct from V. auſtriaca, with which it is generally confounded, and all the varieties of that plant [i]. Willdenow remarks that the ſtem is covered with ſpreading whitiſh hairs.]

41. Lower leaves narrow, cut into fine ſegments. Stalks ſlender, inclining downward. Stem leaves linear, acutely notched. Flowers in long looſe axillary ſpikes (racemes;) they are of a bright blue colour, and ſtand upon pedicels, [which are the length of the bractes or nearly ſo.

The leaves are almoſt like thoſe of Coronopus. Theſe and the ſtem are covered with very minute hairs preſſed cloſe to them. Calyxes five-cleft and ſomewhat hairy. Corolla blue [k].

Native of Auſtria, Carniolia, Sileſia.—Cultivated by Mr. Miller in 1748; it flowers from june to auguſt [l].

42. The ſtem ſeems aſcending, round, ſomewhat hairy. Leaves bright green, half an inch long, crowded, linear, entire, and ſubcuneiform three toothed at the tip, and linear pinnatifid-toothed. Racemes long, axillary. Peduncles ſeveral times longer than the bractes. Calyx four-cleft ſmooth, unequal. Corolla roſe-coloured. Native of Tauris [m].

V. roſea of Desfontaines ſeems to agree with this ſpecies in many reſpects. Stems filiform, pubeſcent, aſcending, many from the ſame tuft. Leaves ſmooth; the lower cuneiform, toothed, obtuſe, decurrent into the petiole; the middle and upper ones pinnatifid, with the ſegments unequal, ſharpiſh, and the terminating lobe a little bigger. Racemes moſtly two or three, naked at bottom. Flowers numerous, crowded, pedicelled. Bracte linear, a little ſhorter than the pedicel. Calyx four-parted; ſegments linear-lanceolate, unequal. Corolla roſe-coloured, the ſame ſize as in V. Teucrium, with ovate obtuſe ſegments, the loweſt ſmaller, as in moſt of the ſpecies. It is allied to V. auſtriaca, but differs in having a ſhrubby ſtem, and terminating racemes [n].—In theſe two reſpects it differs from V. taurica, and alſo in the comparative length of the pedicels and bractes; in other reſpects the two deſcriptions agree. This is a native of Mount Atlas near Tlemſen.

43. Root perennial. Stem filiform, erect, even, a foot high or more. Leaves oppoſite, ſubſeſſile, ovate-lanceolate, like thoſe of Nettle very finely rough-haired. Racemes from the uppermoſt leaves, filiform, ſlender, in flowering time the length of the leaves and more, lax, on capillaceous pedicels. Calyx four-leaved. Corolla fleſh-coloured [o].

Native of Switzerland, Bithynia, Auſtria and Bavaria.—Introduced in 1776, by Joſ. Nich. de Jacquin, M. D. it flowers in june and july [p].

44. This riſes with ſimple ſtems about a foot high, ſometimes ſhooting into one or two branchlets from the upper parts; the leaves are ſeſſile, except the loweſt, which have very ſhort footſtalks: they are ovate, of a dark green, generally cordate at the baſe, unequally ſerrated and of a gloſſy ſurface: the racemes are villoſe and upright; growing to the length of half a foot: the flowers are large and elegant, the tube is whitiſh, but the border of an elegant blue with deeper ſtripes. Native of Auſtria growing in ſhrubby places and about hedges, &c. and ſometimes in meadows [q].

Gouan remarks, that it has five ovate, equal calyx-leaves [r].

Retzius informs us that he received two plants from England under the name of V. latifolia. The firſt he deſcribes as having wider leaves, hirſute, equally ſerrate, ſubſeſſile, the younger ones more manifeſtly petioled. Stem weak, hiſpid in two rows. Racemes la-

teral,

Digitized by Google

teral, long. Calyxes four-leaved, equal, three-nerved, ciliate, lanceolate as well as the bractes.

The ſecond has the ſtem erect, ſtiff, ſlightly tomentoſe. Leaves ſeſſile, hirſute, unequally crenate, but commonly, eſpecially whilſt the plant is in flower, ſo deeply cut, that it may fairly be called pinnatifid. Racemes lateral, but much overtopping the ſtem; and ſo denſe that they ought rather to be named ſpikes. Calyxes five-leaved: leaves unequal, lanceolate, hairy, ſcarce manifeſtly nerved; the fifth very ſmall and linear. Bractes oblong, often toothed. Corolla large blue-purple, turning red in drying.—The latter of theſe is the latifolia and the Pſeudochamædrys of Jacquin deſcribed above.

Native of Germany, Auſtria and Switzerland. Introduced in 1775, by Joſ. Nich. de Jacquin, M. D. It flowers in may and june [t].

Miller ſeems to have intended this by his V. maxima. which he deſcribes as having] the ſtalks ſlender ſtiff and upright; the leaves oppoſite, heart-ſhaped, rough, indented, the lower ones ſmall, the middle ones much larger and diminiſhing again in ſize toward the top; the flowers in long bunches from the upper axils, of a bright blue and appearing in may. He attributes it to Monte Baldo in Italy.

45. Stature of the preceding, but the leaves very narrowly lanceolate, moſtly in threes. Racemes very long, with deep-blue flowers, in threes at the three upper joints. Calyxes four-cleft. Native of Tartary and Bohemia [t].

46. Root fibrous, annual. Stem three or four inches high, erect, branched, downy. Leaves on ſhort footſtalks, acute, ſerrate, ſcarcely hairy. Flowers alternate, peduncled, about the top of the ſtem and branches. Bractes lanceolate, acute, entire, ſlightly ciliate, a little longer than the peduncles. Calyx of the fruit much enlarged, of four ciliate equal ovate acute leaves, marked with three nerves, and not unlike the leaves of ſome ſpecies of Rubia or Galium: they much exceed the corolla and capſule in length. Corolla ſmall, white. Capſule obcordate, downy [u].

According to Vahl, the ſtem is quite ſimple; the leaves ovate, ſmooth, having three or four ſerratures on each ſide: floral-leaves alternate, ſeſſile, lanceolate; flowers drooping; peduncle ſhorter than the floral leaf; ſegments of the calyx ovate, acute, almoſt equal, twice as long as the fruit. It differs from V. arvenſis in having the leaves exactly ovate, acute, ſmooth, ſerrate, and the ſegments of the calyx almoſt equal, twice as long as the fruit.

Tournefort gathered this plant in the corn-fields of Cappadocia.

47. Root annual, ſmall, fibrous. Stems ſeveral, procumbent, long, leafy, round, hairy, not branched except at their baſe. Leaves on ſhort foot-ſtalks cordate-ovate, deeply ſerrate, a little rough and hairy. Flowers on ſimple axillary peduncles, exceeding their correſponding leaves in length, and finally curved downwards. Segments of the calyx four, ovate-lanceolate, obtuſe, ciliate, generally quite entire but ſometimes irregularly toothed. Corolla ſmall, bright blue, falling off on the leaſt touch. Capſule of two round ſwelling lobes, rough-haired; according to Curtis, like that of V. ſerpyllifolia, but larger and rounder. Seeds about ſix in each cell. (Linneus ſays four, Curtis ſix, Scopoli eight to ten, Withering four to eight) externally rugged, cupped or hollowed out on the other ſide, in which hollow the little ſtalk is fixed that attaches them to the ſeed-veſſel. Their whole ſtructure is curious, and totally different from that of V. arvenſis [x]; with which this ſpecies is apt to be confounded, in ſome degree from their ſimilarity, but more perhaps from the ſimilitude of their Latin, and the ambiguity of their Engliſh names. They may be thus diſtinguiſhed: the agreſtis is procumbent, the leaves are petioled, the flowers are on long peduncles, each cell of the Capſule is large and round; and if the form of the ſeeds be adverted to, we ſhall ſee the reaſon of this conſtruction, for inſtead of being ſmall and flat, as in the other ſpecies, they are large, convex on one ſide, hollow on the other, and wholly different in appearance. The arvenſis is upright, the leaves are ſeſſile, and the flowers are on very ſhort peduncles. With us at leaſt it is commonly found on walls [y]; whereas the agreſtis is a moſt common weed in arable fields and gardens, where it is always to be found in ſome ſtage or other, and in flower from the beginning of ſpring to the end of autumn [z].

48. Root annual, fibrous. Whole herb generally paler than in agreſtis and hederifolia, and not ſo apt to turn black in drying. Stem about ſix inches high, (from three to nine,) upright, ſtiff and dry, round, purpliſh, hairy, generally branched at the baſe. Leaves oppoſite, hairy, ſtrongly ſerrate; the lower ones chiefly on ſhort foot-ſtalks; the upper ones, from whoſe axils the flowers are produced, are lanceolate narrow and entire, ſo as more properly to be called bractes; and hence Dr. Withering has removed this and the verna to the ſpiked ſection of this genus, to which however they are not naturally akin, nor ought they to be ſeparated from the other annual ſpecies. The flowers of V. arvenſis ſtand on ſhort pedicels, and are ſmall, pale blue, with four lanceolate, entire, glandular-hairy, rather unequal ſegments to the calyx; the two loweſt, according to Curtis, almoſt twice as large and long as the two others. Capſule obcordate, compreſſed, ciliate, pale brown; containing ſeveral, (about fourteen) ſeeds, which are elliptical, flat, with a little dimple in the middle of one ſide. The form of the ſeeds and of the calyx-leaves will be found to afford the moſt certain marks of ſpecific diſtinction, particularly of the annual ſpecies, in this genus [a].

Mr. Curtis remarks, that it varies in ſize from an inch to ſix or eight inches, that on walls the bottom leaves are frequently purple, that the capſules are much ſmaller than in agreſtis, and when ripe form a ſpike.

Dr. Smith informs us, that about Rome, the flowers of this and the preceding ſpecies, are always white [b].

Native of Europe, Barbary, Japan, and North America. With us in dry gravelly fields, waſte ſandy places, dry paſtures, and on walls; flowering in may.

49. Root annual, ſmall, fibrous. Stems proſtrate, wide ſpreading, round, thickiſh, tender, covered with ſoft hairs; they are hollow, ſurrounded by a ſtrong elaſtic thread-like fibre, as in Alſine media or Chickweed: unbranched according to Dr. Smith, but Mr. Curtis ſays—ſomewhat branched. Leaves alternate on foot-ſtalks various in length, divided into lobes from three to ſix, but five-lobed when perfect, the central lobe being much the largeſt; they are a little fleſhy, and hairy on both ſides. Peduncles longer than the leaves, ſpreading and finally bending downward. The four ſegments of the calyx are large, heart-ſhaped, acute, edged with long white hairs. Corolla pale-blue, ſhorter than the calyx; mouth villoſe within. Capſule large, ſwelling, reſembling two united globes, rather than heart-ſhaped. Seeds two large rugged concave in each cell [c]; or as Curtis deſcribes them, in form not unlike the nectary of the Ladies Slipper, pale brown, hollow within, with a navel-like appearance, externally convex, and grooved or notched.

This has the greateſt affinity to the agreſtis, in habit and place of growth, and in the peculiar formation of its ſeed-veſſels and ſeeds; in which they differ totally from the other Britiſh ſpecies: but though the capſules are nearly of the ſame ſize, yet the ſeeds are conſiderably larger, which accounts for the remarkably large ſeed-leaves which occur in this ſpecies. The leaves alſo are more thinly placed on the ſtems than in the agreſtis, and have ſeldom more than two or four notches on them; and the flowers are of a very pale blue colour [d].

Native of Europe and Barbary, in gardens and corn-fields, where the ſoil is light, in great abundance, flowering in april and may. It flouriſhes ſo through the winter, that it is known in Norfolk by the name of Winter-weed. The old names were Ivy Chickweed and Small Henbit.

Digitized by Google

The leaves are ſometimes more deeply cut than ordinary, and in that ſtate young botaniſts often take this plant for the triphyllos: but if the ſeeds be attended to, no miſtake can happen [e].

β. This variety as Linneus ſuppoſed it to be, is really a diſtinct ſpecies, and has the ſegments of the calyx elliptic, obtuſe, rough-haired all over, not ciliate [f]. It was found by Tournefort in the Archipelago.

50. Root annual. Stems filiform, procumbent. Leaves alternate, on ſhort footſtalks, roundiſh-cordate, having about three notches on each ſide, but not deeply cut or lobed, clothed with a few ſcattered jointed hairs, as in the preceding ſpecies. Flowers axillary, large. Peduncles filiform, downy, three times as long as the leaves. Calyx-leaves equal, lanceolate, ſlightly downy. Corolla twice as long as the calyx, ſpreading, blue. Capſule obcordate, reticulated.

It is like V. hederifolia in many reſpects, but is ſufficiently diſtinguiſhed by its leaves being crenate and not five-lobed, the ſegments of the calyx lanceolate not ovate, and by the very long filiform peduncles.

Gathered by Tournefort in the eaſt. Buxbaum ſays it grows about hedges in Bithynia [g].

51. Root annual fibrous. Stem moſtly branched; branches divaricate-patulous, flexuoſe. Lower leaves entire ſcarcely lobed; upper ſubſeſſile, trifid to the baſe, the central lobe largeſt and obovate, the ſide ones moſtly two-parted. Flowers on peduncles ſhorter than the leaves, erect as are alſo the fruits. Segments of the calyx obovate-oblong, obtuſe, ciliate, unequal. Corolla deep blue. Capſule orbicular, emarginate, compreſſed. Seeds numerous, obovate, flatted. The herb turns black in drying [h].

Stems viſcid on the upper part, pale green or reddiſh, drooping a little during the period of flowering. Leaves ſpreading, rather remote, alternate and oppoſite, thickiſh, hairy on both ſides, often reddiſh on the under ſide; the lowermoſt cordate-ovate, on very ſhort petioles; the upper ones ſeſſile, fingered, or divided deeply into five and three parts. Corolla ſmaller than the calyx, both deeply divided into four ſegments. Capſule large. Seeds blackiſh-brown, convex, gibbous, and wrinkled on one ſide, hollow on the other.

Its divided leaves, the deep rich blue colour of the flowers, and the largeneſs of its ſeed-veſſels obviouſly diſtinguiſh this from any other Britiſh ſpecies. Its name triphyllos is not always ſtrictly applicable, the leaves, in young plants particularly, being often divided into more than three ſegments [i].

The ſtem is ſometimes unbranched. Branches from the bottom of the ſtem or near it, and riſing to the ſame height. Root-leaves undivided, rarely found; well repreſented in John Bauhin's figure. Lower ſtem-leaves heart-ſhaped, jagged. Although theſe ſometimes reſemble thoſe of the hederifolia, the deep finger-like diviſions of the upper leaves, and the want of leaf-ſtalks, prevent all poſſibility of their being miſtaken [k]. V. triphyllos is always much larger and more diffuſe than the verna, its leaves more deeply divided, and their ſegments more or leſs obovate; neither is it quite ſo rare a plant. It flowers early, and like the verna, varies much in ſize, according to the ſhare of nouriſhment it meets with [l].

This plant, which is common to moſt parts of Europe, and chiefly found in corn-fields where the ſoil is light, is of very partial growth in this country, being found principally in the ſandy tract, which connects Norfolk and Suffolk. Thomas Williſel found it in ſeveral parts of this tract. Sir John Cullum and his brother Sir Thomas Gery Cullum have obſerved it about Bury: and Mr. Woodward both there and near Cockley Cley in Norfolk. Mr. Tofield gathered it near Roſſington in Yorkſhire; and Sir Thomas Frankland in the ſame county. It flowers in march and april, and the ſeeds ripen in june [m].

52. In habit, paleneſs of colour, never drying black, form of the ſeeds, and ſituation of the flowers, this is very nearly allied to V. arvenſis, but it is abundantly different from it in the deep diviſion of the leaves, with the central lobe obovate, obtuſe as in the preceding; the floral ones alſo three-parted. Stem ſcarcely a finger's length, ſtiff, often branched. Segments of the calyx lanceolate, acute, nearly equal. Capſule obcordate, compreſſed [n].

Calyx much longer than the corolla, and deeply divided into four lanceolate blunt unequal ſegments. Corolla blue, with a green baſe. Floral leaves lanceolate, blunt. Peduncles very ſhort, indeed ſo ſhort as to give the aſſemblage of flowers the appearance of a ſpike [o].

Native of many parts of Europe. Firſt found in England by the late Sir John Cullum, Bart. in dry ſandy fields near Bury in Suffolk; flowering in april and may. It has been ſince found in Norfolk, at Foulden, by James Crowe, Eſq. Mr. Woodward remarks, that this little plant is ſometimes near buried in the driving ſand.

Dr. Smith ſuggeſts, that from its near reſemblance at firſt ſight, eſpecially when luxuriant, to V. arvenſis, it may perhaps have been overlooked for that plant [p].

β. V. ſucculenta of Allione is conſidered as a variety of this. He deſcribes the ſtem as filiform, erect, hardiſh, the height of a finger or a ſpan. Leaves oppoſite, petioled, thickiſh, green, ſmooth, linear, toothed on each ſide; above the third or fourth pair of ſtem-leaves comes out a long thin ſpike. Floral leaves alternate, quite entire; from the axil of each a one-flowered peduncle. Fruit cordate, wider and ſhorter than the calyx, containing from ſix to eight darkiſh, compreſſed ſeeds. It differs from V. verna, to which it is very nearly allied, by its ſucculent leaves with the teeth not ſharp, and all the floral leaves quite entire.

53. Root annual. Stem herbaceous, erect, hairy at top, having two or four quite ſimple oppoſite branches at the baſe almoſt the height of the ſtem. Leaves thickiſh, all parted: the lower of two pairs, oppoſite, trifid; with the ſegments ovate, the lateral ones ſhorter, narrower: the ſtem-leaves or rather floral leaves, for the ſtem bears flowers almoſt from the baſe, are alternate and hairy at their baſe: the lower ones are five-parted; the uppermoſt three parted, with linear obtuſe ſegments, a little narrower at the baſe. Flowers axillary ſeſſile, the lower more remote, the upper more crowded. Calyx four-parted, length of the capſule, with lanceolate, ciliate ſegments, two of them ſhorter. Capſule obcordate, with diverging lobes.

It differs from V. triphyllos in having ſeſſile flowers, the ſegments of the leaves linear, and the capſules obcordate; from V. verna in having all the leaves parted.

Native of the ſouth of France about Montpellier, of Spain and Bohemia [q].

54. Stem upright, round, pubeſcent, with oppoſite branches. Stem-leaves conjugate; floral leaves alternate: each pair of the former is diſtant from the next; they are almoſt orbicular, obtuſe, widely and bluntly toothletted, ſlightly hairy, on ſhort petioles [r].

Native of Germany, Switzerland, Piedmont, &c. It flowers in may.

This ſeems to be the romana of Allione, Schmidt, Villars and Scopoli.

55. This reſembles the preceding, but the leaves are ſtraight and entire, and the flowers are ſeſſile; the ſtem is ſmooth [s].

Stem erect, ſimple, or ſometimes branched only from the lower axils. Leaves lanceolate-linear, ſeſſile, the upper ones alternate, the lower oppoſite, here and there bluntly toothed, the reſt quite entire, blunt. Flowers axillary, ſeſſile among the bractes. Calyx four-leaved [t].

Native of the North of Europe, Germany, Dauphiné and Italy. Gathered alſo by Commerſon at Buenos Ayres.—Cultivated in 1680, according to Moriſon. It flowers in may and june [u].

V. romana of Linneus ought to be excluded. All its ſynonyms in the firſt edition of Species Plantarum, belong to V. acinifolia; and the ſpecimen in the Linnean herbarium, from which the ſpecific difference and

deſcription

Digitized by Google

deſcription in the Mantiſſa were made, is moſt certainly nothing elſe than V. peregrina[x].

56. Stem ſimple, a finger's length, flowering from top to bottom. Leaves on ſhort petioles, alternate, blunt, ſhorter than the calyxes, quite entire except the two leaves next the root, in which a tooth or two may be diſcovered by means of a magnifying glaſs. In each axil is a ſmall flower, bright blue, on a very ſhort peduncle, leſs than the calyx. Calyx-leaves equal, linear, longer than the internodes. Fruit cordate, large in proportion to the plant, ſhorter than the calyx-leaves, but much wider. The whole plant is hirſute.

It approaches to the verna, but differs in the ſtem being ſimple and covered with flowers, the leaves linear not parted, all alternate. It differs alſo from V. peregrina in the ſtem being quite unbranched, the leaves ſhorter and the calyxes longer than the fruit.

Native of Piedmont, in paſtures[y].

57. Native of North America.]

PROPAGATION AND CULTURE.

The perennial ſorts may be increaſed by parting their roots which may be done every other year; for if they are not often divided, many of them will grow too large for the borders of ſmall gardens: yet they ſhould not be parted too ſmall, becauſe when there is not a number of ſtems ſo as to form a good bunch, the plants have but a mean appearance. Michaelmas is the beſt time to part the roots, that they may be well eſtabliſhed before winter: and when they are removed in the ſpring, they ſeldom flower ſtrong the ſame year, eſpecially if the ſeaſon prove dry. Thoſe which grow pretty tall are proper to plant in the borders of ornamental plantations; but thoſe with trailing branches are fit for banks or irregular ſhady ſlopes. They are moſtly hardy, and require only to be weeded, and tranſplanted every ſecond or third year.

The annual ſorts may be propagated by ſeeds ſown in autumn: and many of them will maintain their ground, if their ſeeds be permitted to ſcatter.

If theſe plants are placed in a ſhady border, they will thrive much better than when they are more expoſed to the ſun, and their flowers will continue much longer in beauty.

[19. V. decuſſata is a hardy greenhouſe plant, and may be placed with the Myrtles. In mild winters it will even ſtand ſecure in the open air, in a warm ſoil and ſheltered ſituation. It is uſually and readily increaſed by cuttings[z].

DESCRIPTIONS, *&c.*

1. α. The leaves of the ſmall or hairy-leaved Lauruſtinus are ſeldom more than two inches and a half long, and an inch and quarter broad; they are rounded at their baſe, but end in acute points, are veined and hairy on their under ſide, and not of ſo lucid a green colour as the next variety on their upper. The umbels (cymes) of flowers are ſmaller, and appear in autumn, continuing all the winter. The plants are much hardier.

β. The ſtalks of the Shining-leaved Lauruſtinus riſe higher, and the branches are much ſtronger. The bark is ſmoother, and turns of a purpliſh colour. The leaves are larger, of a thicker conſiſtence, and of a lucid green green colour. The umbels (cymes) are much larger, and ſo are the flowers. Theſe ſeldom appear till the ſpring, and when the winters are ſharp, the flowers are killed, and never open unleſs they are ſheltered.

There is a variety of this with variegated leaves; [both gold and ſilver ſtriped, and ſome other trifling varieties [a].

The branches are warted, the younger ones four-cornered. Leaves oppoſite, ovate, on ſhort petioles, rigid, ſhining, perennial; the younger ones hirſute

[a] Curt. magaz.

Digitized by Google

with ſhort ferruginous villoſe hairs. Flowers in crowded cymes, with little bractes between them. Corolla white. Berries, when ripe, blue [b].

γ. Leaves narrower, hairy only on the edge and veins underneath. Fruit ſmaller.

δ. Difference given in the character.

Native of the South of Europe and of Barbary. α β in Portugal and Spain: α in the county of Nice: β about Algiers and in mount Atlas: γ in Italy, about Rome, Tivoli, and near Montpelier, obſerved by Ray. —Cultivated by Gerarde in 1596 [c].

The old authors gave it the name of Lauruſtinus, from a ſuppoſition that it was a ſmaller ſpecies of Bay; accordingly Gerarde and Parkinſon name it the wild Baye tree; but the Latin name has obtained, and this ſhrub is generally known by that of Lauruſtinus in England. Τυνος or τυννος is ſmall; and hence our Engliſh word *tine* or tiny.

The berries are very hot and inflame the fauces violently, like thoſe of Mezereon and Spurge Laurel; they purge violently according to Parkinſon. Yet Lobel aſſerts that the Starlings frequent the ſhrubs in great flocks, and devour the berries greedily [d]: which is not improbable as Blackbirds and Thruſhes do the ſame by thoſe of Mezereon.

2. This is very like the preceding, but the leaves of V. Tinus are exacty ovate, the petioles are longer, the peduncles and ſtem angular, and ſmooth. Native of South America, where it was found by Mutis [e].

3. This ſhrub is a fathom in height, with an aſh-coloured bark. Branches round, hoary. Leaves petioled, oppoſite, acute, ſmoothiſh above, but hoary-villoſe beneath. Petioles of a middling length, four-ſided, channelled, hoary: the hoarineſs conſiſting of ſtellate villoſe hairs heaped together. Cymes terminating, compound, ſix-rayed, ſubdivided by threes. Common peduncles length of the leaves, ſolitary, erect, hoary: rays or partial peduncles an inch long, angular, three-cornered; pedicels one-flowered on the third ſubdiviſion. Calyx ferruginous-villoſe. Corolla whitiſh, with roundiſh ſpreading ſegments. Filaments longer than the corolla. Germ villoſe. Berry ovate, oblique, crowned by the calyx at the ſide. Seed oblique—are there not two abortive? Native of Jamaica, on the mountains in the ſouthern part. It flowers in autumn [f].

4. Leaves narrower, oblong, acuminate both ways, on ſhort petioles. Cymes terminating the ſhorter branches, villoſe. Rays ſpreading, with the flowers turned upwards and ſmall. Each ray is terminated by a larger white flower, as in V. Opulus, with unequal petals, the outer one largeſt and obcordate [g].

Stem fruteſcent, branched. Branches and branchlets alternate, round, aſh-coloured, ſmooth, climbing. Leaves oppoſite, ovate-oblong, entire at the baſe and point, very finely ſerrate in the middle, thin, quite ſmooth, bright green, paler beneath, equal, an inch and half long. Calyx reflexed. Filaments ten. Styles three, divaricating. It differs from V. Caſſinoides in having the petioles not at all keeled, and the leaves ſerrate. Native of Japan [h].]

5. This has a ſtrong ſtem, covered with a brown ſmooth bark, and riſing to the height of ten or twelve feet, ſending out woody branches on every ſide the whole length, which have a ſmooth purpliſh bark. Leaves oppoſite, five inches long and two and a half broad, ſmooth and of a lucid green above, veined and of a light green beneath, entire at the edges, (indiſtinctly notched,) and rounded at both ends; of the ſame thickneſs with thoſe of the broad-leaved Lauruſtinus. The flowers are produced in large umbels (cymes) at the end of the branches: they are in ſhape and colour like thoſe of the common Lauruſtinus, but ſmaller; and the ſtamens are much larger than the corolla. They appear in july, and are ſucceeded by roundiſh berries, which, when ripe, are black; but theſe rarely ripen in England. There ſeem to be two varieties of this ſhrub; one growing in the northern parts of Virginia and Maryland, which caſts its leaves in winter; the other in Carolina, which is an evergreen. [This apparent difference is probably owing to climate. And by Mr. Miller's confeſſion, they are ſo much alike in ſummer, as ſcarcely to be diſtinguiſhed.—Cultivated by him in 1758. It flowers in may and june [i].

The cymes in this are naked; in the preceding ſpecies they are involucred [k].]

6. This riſes with a woody ſtalk ten or twelve feet high, covered with a brown bark, and branching its whole length: the branches when young, are covered with a ſmooth purple bark. Leaves two inches long, and an inch and quarter broad, ſlightly ſerrate, and on ſhort ſlender foorſtalks, oppoſite or without order. Flowers in ſmall umbels (cymes) lateral and terminating; theſe are white, and ſmaller than in the V. Lantana, appear in june, and are ſometimes ſucceeded by berries; but they do not ripen here. It grows naturally in moſt parts of North America, where it is commonly called Black Haw. [Cultivated in 1731, as appears from the firſt folio edition of Mr. Miller's Dictionary [l].

7. A ſhrub ſmaller than Lonicera Xyloſteum, upright, with ſlender, jointed, ſtraight, oppoſite, ſpreading branches, covered with a whitiſh-gray bark. Leaves fewer, oppoſite, petioled, hoary underneath. Peduncles terminating, between the laſt pair of leaves, length of the petioles bifid, each ſuſtaining two, four or five ſeſſile flowers. Calyx none, except a rim crowning the germ, which is cylindrical and ſtriated. Corollas yellowiſh-white, equal, ſmall, bell-ſhaped, five-toothed at the edge. Stamens length of the corolla, with large twin anthers. Germ prominent within the flower with a very ſhort navel, and a truncate ſtigma. Berry globular, large, ovate-depreſſed, convex on the outſide, containing five or ſix, ſometimes ſeven ſeeds [m]. Native of Ruſſia and Siberia.

Pallas at firſt made this ſhrub a ſpecies of Lonicera, but afterwards corrected himſelf, and brought it into this genus.]

8. Stalks ſoft and pithy, branching out greatly from the bottom upward, and covered with a gray bark. Leaves three inches long, and nearly as broad, ſtrongly veined, of a light green colour, placed oppoſite upon pretty long footſtalks. Flowers in terminating corymbs, white and almoſt as long as thoſe of V. Lantana, appearing in june, but not ſucceeded by berries in England.

[This is a ſmall ſhrub, with ovate, acuminate, oppoſite, footſtalked leaves, ſmooth above, and very ſlightly pubeſcent beneath, ſharply ſerrated; at their firſt expanſion much plaited in the direction of the fibres, but afterwards much more plain or flat: on the younger flowering branches they are ſometimes ternate. Cymes terminal: Flowers white [n].

Native of North America. Introduced in 1736, by Peter Collinſon. There are two varieties of it, one with the leaves ſmooth on both ſides; the other with the leaves downy underneath and drawn out to a point [o].

9. Leaves more round, and the teeth more tender than in the preceding, for which Thunberg at firſt took it: they are plaited, eſpecially before they are well opened. Flowers radiate. Native of Japan, about Fammatats, in Fakona, and elſewhere; flowering in april and may [p].

10. Stem upright, ſhrubby: branches oppoſite, angular, aſh-coloured, ſmooth, from ſpreading upright. Leaves oppoſite, thin, ſmooth, pale beneath, unequal, the loweſt entire at the baſe, the uppermoſt larger, two inches long, on very ſhort petioles. Flowers in a decompound umbelled panicle terminating the branchlets, not radiate. Peduncles and pedicels angular, hairy. Bractes briſtle-ſhaped, hairy. It differs in having ovate leaves thickly toothed with ſharp teeth, and drawn out at the end into a very long point. Native of Japan.

Viburnums vary: 1. With radiate and non-radiate

[b] Desfontaines. [c] Hort. kew. [d] Ray hiſt. [e] Linn. ſuppl. [f] Swartz deſcr. [g] Linn. ſuppl. [h] Thunberg. [i] Hort. kew. [k] Linn. ſpec. [l] Hort. kew. [m] Pallas roſſ. 1. 59. [n] Jacquin. [o] Hort. kew. [p] Thunb. in Linn. tranſ. and Fl. japon.

flowers.

V I B

flowers. 2. With a ſingle ſtyle and three piſtils. 3. With five and ten ſtamens [q].

11. This is a thickly-branched ſhrub or ſmall tree, having round, pliant, mealy twigs, (whence one of its Engliſh names, Pliant Mealy Tree,) with the ſame kind of tufted ſtellated pubeſcence as is found on the flower-ſtalks, backs and even upper ſurfaces of the leaves. Leaves oppoſite, as in the whole genus, ſomewhat elliptical, cordate, obtuſe, ſerrate, ſtrongly veined, turning dark red before they fall in autumn. Stipules none. Flowers in large terminating, ſolitary, many-flowered cymes. Corolla white, cloven half way down, ſpreading. Stamens inſerted between the ſegments. Anthers yellowiſh. Stigmas ſeſſile, very ſhort, obtuſe. Berries compreſſed, having a little mealy aſtringent pulp, when young red on the outſide, yellow on the other, when ripe black. Seed large, cordate, flat and furrowed [r].

Native of moſt parts of Europe, except the moſt northern countries; with us chiefly in a calcareous ſoil, in woods and hedges, flowering in may. Dr. Withering ſays that the bark of the root is uſed to make bird-lime.

It is commonly taken to be the Viburnum of Virgil, but the Poet ſays nothing by which it can be aſcertained, except that being contraſted with the tall Cypreſs, we may ſuppoſe it to be a low ſhrub. Viburna in the plural ſeems to have been taken by the ancients for any ſhrubs which were uſed for binding or tying. In the north of England, Ray ſays, it grows to a larger ſize than in the ſouth, which ſeems odd, as it is rather a ſouthern than a northern ſhrub. Mr. Miller ſays it riſes near twenty feet high, but he gives the leaves nine inches in length, which is certainly much beyond the truth.

There is a variety in North America, with much larger leaves, that are bright green.] And there is another in our nurſeries with variegated leaves; but they become plain, when the ſhrubs are removed into good ground, and grow vigorouſly.

[12. Branches round, ſmooth, tinged with red, divaricating, ſubdivided. Leaves oppoſite, ovate not cordate, nerved, downy beneath eſpecially the upper ones. Petioles, branchlets and peduncles downy. Umbels axillary at the ends of the branchlets, with radiant flowers. It differs from V. Lantana in having ovate leaves, not cordate, and lateral crowded umbels. Native of Japan, in woods between Miaco and Jedo. It is alſo cultivated; and flowers in april and may [s].

13. Stem flexuoſe-erect, round, ſmooth. Branches and branchlets alternate, round, ſmooth at the baſe, rough-haired at the top. Leaves oppoſite, reſembling thoſe of the Nettle, acute, deeply and equally ſerrate, veins rough with white decumbent hairs, an inch long. Petioles and peduncles rough with horizontal hairs. Umbels terminating, compoſed of very ſmall flowers not radiating. Stigma two-lobed. Native of Japan [t].

14. Native of Virginia. Introduced in 1736 by Peter Collinſon. It flowers in july [u].

15. So nearly allied to the preceding as to be ſcarcely diſtinct, but the leaves are groſly toothed inſtead of being ſharply ſerrate as that is; the ſeed alſo is oval, on each ſide two-channelled and triconvex as in V. Lantana, not cordate as in the preceding [x]. Native of the Levant and Ruſſia.

16. It is a ſmall buſhy tree, ſmooth in all its parts, and very much branched: branches oppoſite, round. Leaves ſubcordate, with three great unequally ſerrate lobes, veined, paler beneath; their petioles bearing ſeveral cup-like glands towards the top, and a pair or two of erect linear appendages, ſcarcely to be called ſtipules, near the baſe. Cymes terminating, ſolitary, compoſed of many white flowers, radiant; the inner perfect, ſmall, reſembling thoſe of Elder, thoſe in the margin abortive, conſiſting merely of a large irregular flat petal without any organs of fructification. Stigmas nearly ſeſſile, cloſe together. Berries drooping, globular, crowned with five very ſmall ſcales of the calyx, red, very ſucculent. Seed flat, heart-ſhaped, the breadth of the berry, prominent on one ſide, grooved on the other, teſtaceous [y].

[q] Thunb. jap. [r] Smith brit. and engl. bot. [s] Thunberg. [t] Idem. [u] Hort kew. [x] Willdenow. [y] Smith brit. and engl. bot. Gærtner.

The neuter florets in the circumference expand firſt, and drop before the perfect florets do ſo. The cymes have five or ſeven rays [z].

Native of Europe; common with us in woods and hedges in watery places, flowering early in june; the bright-red berries ripen about ſeptember, and towards the middle of october the leaves aſſume a beautiful pink colour, affording another inſtance, in addition to the Cornel of a genus, moſtly American, the leaves of which turn red in autumn [a].

β. The American ſhrub has the twigs of a ſhining red colour; whereas in the european they are green and opaque. Mr. Miller makes a diſtinct ſpecies of this variety. He deſcribes it as] riſing eight or ten feet high, with many ſide branches, covered with a ſmooth purple bark: the leaves cordate-ovate, ending in acute points, deeply ſerrate, having many ſtrong veins, and ſtanding upon very long ſlender foot-ſtalks. Cymes, flowers and berries as in the European ſhrub. Native of South Carolina, and ſome other parts of North America.

γ. [The beautiful variety ſo common in plantations, bearing large round bunches of abortive flowers only, and grouping ſo elegantly with Lilac and Laburnum in the early part of ſummer [b],] will riſe to the height of eighteen or twenty feet, if permitted to ſtand. The ſtem becomes large; the branches grow irregular and are covered with a gray bark. The leaves are divided into three or four lobes, ſomewhat like thoſe of the Maple: they are about three inches long, and two and a half broad, jagged on their edges, and of a light green colour. The flowers come out in a large corymb, are very white, and being all neuters, are barren. From their extreme whiteneſs, and ſwelling out into a globular form, ſome country people have given this ſhrub the name of Snow-ball tree, [which ſurely is preferable to the common appellation of Guelder Roſe, and is conformable to the Schneeball of the Germans. Probably we had this ſingular variety from the Dutch, who call it Ghelderſche Rooſe. Gerarde calls it "Elder Roſe and Roſe Elder, ſays it groweth in gardens, and the flowers are there doubled by art, as it is thought." It is more probable that accident originally produced the variation, and that it was improved by art.

17. Stem upright, ſomewhat angular, aſh-coloured, villoſe. Leaves nerved, villoſe on both ſides, unequally toothed and as it were gnawn, two inches long, the lower ones ſmaller. Petiole round, villoſe, half an inch long. Flowers in panicles, not radiate. Panicle axillary, ſuperdecompound, four-cleft and trichotomous, ſpreading very much. Peduncles and pedicels tomentoſe. Style ſimple, very ſhort, with an obtuſe ſtigma. Native of Japan.

18. The whole plant is ſmooth. Stem and branches round. Leaves nerved, paler beneath, a hand wide and a little more in length. Petioles three times ſhorter than the leaf. Umbel terminating, compound, with radiant flowers. Native of Japan.

19. Leaves equally and acutely ſerrate, villoſe with ſcattered hairs, almoſt a hand broad, and a little more in length. Umbel ſuperdecompound, terminating with radiant flowers. Native of Japan [c].

20. Branches bent or hanging down. Petioles waving on the edge. Leaves thick, like thoſe of V. Tinus, ſmooth, ſerrulate with very ſmall teeth. Germ terminating, awl-ſhaped, ventricoſe at the baſe. Native of North America; found in Canada by Kalm [d]. Cultivated in 1761, by Mr. James Gordon. It flowers here in july [e].

21. Loweſt leaves obovate; the next ovate; the upper ones lanceolate. Native of North America [f]. Cultivated here at the ſame time by Mr. Gordon. It flowers in june [g].

22. Native of North America. Cultivated in 1758, by Mr. Chriſtopher Gray. It flowers in may and june [h].

23. Leaves petioled, broad-lanceolate, ſharpiſh, without any raiſed veins. Petioles decurrent along

the back, whence the twigs are ancipital. Corymbs ſhort[i].]

Stem twelve or fourteen feet high, ſending out branches from the bottom to the top. Leaves about an inch long, and more than half an inch broad, of a light green colour, oppoſite on ſhort footſtalks. Peduncles axillary, very ſhort, ſupporting ſmall umbels of white flowers, which appear in july; but are rarely followed by ſeeds in England. Native of South Carolina. [Cultivated in 1724, as appears from Furber's catalogue[k].]

PROPAGATION AND CULTURE.

1. The Lauruſtinuſes are propagated by laying down their young branches, which put out roots very freely, ſo that when they are layed in autumn, they will be well rooted by that time twelve months, when they ſhould be taken from the old plants, and may either be planted where they are to remain, or into a nurſery for two years to get ſtrength. The beſt ſeaſon to tranſplant theſe is at Michaelmas, that they may get new root before winter; for as thoſe plants begin to flower early in winter, it is a plain indication of their growing at that ſeaſon, and they will more ſurely ſucceed then, than at any other time of the year: but they may be removed in the ſpring with balls of earth to their roots, provided it is done before they begin to ſhoot: they may alſo be removed at the end of july or the beginning of auguſt, if rain ſhould happen at this ſeaſon; for after they have done ſhooting, which is ſoon after midſummer, they will be in no danger, provided they are not kept too long out of the ground.

Theſe plants may alſo be increaſed by ſeeds, which ſhould be mixed with earth in autumn, ſoon after they are ripe: theſe ſhould be expoſed to the open air, and receive the rain in winter, and in the ſpring they may be ſown upon a gentle hot-bed, which will bring up the plants; they ſhould remain in the bed till autumn, and then may be tranſplanted, and treated in the ſame way as the layers. I have raiſed many of theſe plants from ſeeds, and find them hardier than thoſe raiſed by layers.

Some perſons train up the Lauruſtinus with naked ſtems to round heads; but if theſe are planted in the open air, they will be in more danger of ſuffering by ſevere froſts, than thoſe that have the branches growing rude from the bottom; for if the froſt kills the outer part of the ſhoots, the ſtems will be protected, and will ſoon put out new branches; but where the ſtems are naked, the froſt frequently kills them to the root.

[We ſcarcely recollect a plant, ſays Mr. Curtis, whoſe bloſſoms are ſo hardy as thoſe of the Lauruſtinus; they brave the inclemency of our winters, and are not deſtroyed but in very ſevere ſeaſons. The ſmoke of London is highly detrimental to its growth. It thrives beſt in ſheltered ſituations and a dry ſoil. The ſhining-leaved variety is the moſt ornamental, but at the ſame time the moſt tender.]

8. This is generally propagated here by layers, for the ſeeds do not ripen in England. The young ſhoots take root very freely. The cuttings will alſo take root, if planted in autumn. The ſeeds, when brought to England, almoſt remain in the ground a year, ſo that this is a tedious method.

11. The Wayfaring tree may be propagated either from ſeeds or layers; but the former method is ſeldom practiſed, becauſe the ſeeds rarely grow the firſt year, and the branches eaſily put out roots.

The beſt time for laying thoſe branches is in autumn, juſt as the leaves begin to fall. By the ſucceeding autumn they will be rooted, when they may be removed into a nurſery for two or three years, and then planted where they are to remain. This ſort is very hardy.

The ſtriped variety may be propagated by inarching or budding upon the plain ſort; but there is no great beauty in it.

The American variety is much ſuperior to the European.

[i] Linn. mant. [k] Hort. kew.

16. The Water Elder may be increaſed in the ſame way as the Lauruſtinus, and requires the ſame treatment; it loves a ſoft loamy ſoil, and ſhould have a ſheltered ſituation.

β. The American variety is eaſily propagated by layers or cuttings.

γ. The Guelder Roſe ſends out plenty of ſuckers, by which it is frequently increaſed; but the plants ſo raiſed being very ſubject to put out ſuckers, they are not ſo good as thoſe which come from layers or cuttings. It loves a moiſt ſoil, in which it will make much greater progreſs, and produce flowers in greater plenty than on a dry ſoil.

23. This is tender whilſt young, and requires to be ſheltered under a common frame in winter, till the plants have obtained good ſtrength; when, if they are planted againſt a warm wall, they will reſiſt the cold of our ordinary winters very well, and make good progreſs; but as they are liable to be killed by ſevere cold, it will be proper to keep a plant or two in pots, to be ſheltered in winter. This may be propagated by laying down the branches, which will take root in one year.

[The other North American ſorts (6. 14. 20. 21. 22.) are hardy enough, and may be increaſed by layers or cuttings.

VIBURNUM. See *Hydrangea* and *Lantana*.]

VICIA *(of Pliny, Virgil, &c. According to Varro,* à vinciendo, *becauſe it has tendrils like the vine, by which it binds other plants. But Voſſius rather thinks it is from the Greek, for the Aſiatic Greeks call it* βικιον, *according to Galen; other derivations, leſs probable, may be ſeen in Voſſius, etym.)*

Claſſ. 17. 4. Diadelphia Decandria.

Nat. Order of *Papilionaceæ* or *Leguminoſæ*.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular, erect, half-five-cleft, acute: upper teeth ſhorter, converging, all of equal breadth.

COR. papilionaceous. *Banner* oval, with a broad oblong claw, at the tip emarginate with a point, bent back at the ſides, with a longitudinal compreſſed raiſed line. *Wings* two, oblong, erect, half-cordate, with an oblong claw; ſhorter than the banner. *Keel* with an oblong two-parted claw, the belly compreſſed ſemiorbicular; ſhorter than the wings.

STAM. *Filaments* diadelphous, ſingle and nine-cleft. *Anthers* erect, roundiſh, four-grooved. A nectareous gland ſprings from the receptacle between the compound ſtamen and the germ, ſhort, acuminate.

PIST. *Germ* linear, compreſſed, long. *Style* filiform, ſhorter, aſcending at an erect angle. *Stigma* obtuſe, tranſverſely bearded below the tip.

PER. *Legume* long, coriaceous, one-celled, two-valved, terminated by a point.

SEEDS ſeveral, roundiſh.

OBS. Faba Tournef. *has oval compreſſed ſeeds.* Vicia Rivin. *has roundiſh ſeeds.*

ESSENTIAL CHARACTER.

Stigma tranſverſely bearded on the lower ſide.

SPECIES.

DESCRIPTIONS, &c.

* 1. The loweſt leaflets approximate to the ſtem, are ſeſſile, and conceal the very ſmall ſtipules. Flowers very pale yellow [l].

Root perennial. Stem upright, not ſeldom climbing to the height of a man among buſhes, angular, grooved, bright green, ſmooth, branched. Leaves compoſed of four or five pairs of leaflets, the loweſt pair inſerted into the ſtem itſelf at the baſe of the rib; the other leaflets are ſubſeſſile, almoſt two inches long, and from an inch to an inch and half in breadth, blunt, with a ſpinule, quite entire, glaucous, ſmooth. Stipules at the baſe of the rib, lanceolate, acuminate, toothletted at the baſe, pale green, ſmooth. Peduncles axillary, almoſt as long as the midrib, grooved, ſmooth, in fruiting time ſtraight, bent down, horizontal. Flowers ſmall, ſtriated. Legumes pendulous, an inch and half long, three lines and more broad, terminated in front by a beaked point, ſwelling in the middle, but flattiſh next the ſutures, ſmooth, yelloviſh-brown when ripe. Seeds three, four or five, orbicular or nearly ſo, quite ſmooth, brown, or ruſty black, with a whitiſh ſtreak on one ſide, the ſize of a pea [m].

Haller ſays that this is the largeſt of the European ſpecies of Vetch, having a ſtem ſeveral feet high, branching and full of leaves: ſtipules large, yet covered by the loweſt leaflets, which are from four to ſix or eight, very large, ſcarcely ovate, but almoſt oval, emarginate, ſmooth and nerved; thoſe next the ſtem ſo large that they ſeem to be perfoliate: tendrils branched; flowers pendulous, to thirty in a raceme: all the teeth of the calyx awned, the two upper ones ſhorter: claw of the banner wide, but the end not wide, ovate, reflexed, emarginate; wings a little ſhorter, ovate with large hooks; keel a little ſhorter, cloven, with a blunt beak curved a little. Legumes ſhort and broad, ſcarcely longer than the leaf.

Native of Germany, and Auſtria.—Cultivated in 1758 by Mr. Miller. It flowers here in july and auguſt [n].

2. This differs from the preceding in the flowers not being yellow; in the leaflets being longer, and the loweſt not adhering to the ſtem [o].

[l] Linn. ſpec. and ſyſt. [m] Pollich. [n] Hort. kew. [o] Linn. ſpec.

Stems

Digitized by Google

Stems angular, branched and high. Stipules half-mooned, toothed with a thread at the end of each tooth: Leaflets large, an inch long, oval, ſmooth, tender, deep green, ſix or eight, almoſt alternate and obtuſe, with a ſalient nerve at the end. Flowers large, ſix or eight, purpliſh blue. Legumes ſmooth, flatted, pendulous, containing five or ſix ſeeds. Root perennial [p].

Native of France, Germany, Auſtria, Switzerland, Piedmont and Siberia.—Cultivated by Mr. Miller, in 1759. It flowers in may [q].

3. Stems numerous, and ſo much branched as to choak whatever they grow near. Leaves with eight or nine pairs of leaflets, and terminated by a long and very much branched tendril. Leaflets ovate, oftener alternate than oppoſite. Stipules in pairs, ſmall, deeply divided into ſeveral awl-ſhaped ſegments. Peduncle long, large, four-cornered and ſtriated, growing erect, and bearing on its upper part numerous flowers, growing in an irregular manner, but moſtly by twos and threes with interruptions, pendulous. Teeth of the calyx awl-ſhaped, uppermoſt ſhorteſt. Corolla rather large: ſtandard and wings whitiſh beautifully ſtreaked with blue; keel pale blue [r].

The perennial root throws out many weak ſmooth grooved zigzag ſtems, climbing ſix or ſeven feet high. Leaflets exactly oval, or rather a little obtuſe, tipped with a minute briſtle, ſmooth. Flowers very ornamental. Pods lanceolate, ſmooth, pale brown [s].

Dr. Withering remarks, that the ſtandard of the corolla is without a ſharp point in the notch, the keel not ſhorter than the wings; the ſtyle and ſtigma ſo ſlender, that one cannot certainly diſcern the beard on the under ſide at the end.

Mr. Swayne obſerves, that it is the moſt beautiful climber of this iſland, both leaves and flowers being extremely elegant. It flowers from the end of june through auguſt.

According to Dr. Abbot, the fringes of the leaf-ſcales, (by which I ſuppoſe he intends the ſtipules,) ſet this plant apart from all the others.

This Vetch was long ſuppoſed peculiar to the montainous parts of England, Scotland and Wales, in our iſland; as in ſeveral woods and thickets in Weſtmoreland, Cumberland, Yorkſhire and Worceſterſhire; under Saliſbury-Craigs, and at Cartland-rocks, near Lanerk, &c. in Scotland. Near Caerwent, in Monmouthſhire. Yorkſhire; near Hackneſs, about Greta bridge, Malham near Settle, &c. Weſtmoreland, about Kirby Lonſdale and Kendal. Orton in Cumberland. Woods about Newton Cartmel. Urſwick woods, climbing up the trees for ſeveral yards. Derbyſhire, on hedges behind Matlock bath. Worceſterſhire on the north ſide of Bredon hill, and in the woods about Clifton-upon-Teme, in moiſt places. On Shelton bank near Salop. In a hedge going down Stoke hill from Bull-barrow, Dorſetſhire, by Dr. Pulteney. Beech wood, cloſe by the monument on Lanſdown, Bath; in Smokhall wood, Bath. About the Devizes in Wiltſhire. It has lately been found in the leſs mountainous parts of England, as in Hall wood, Wood Ditton near Newmarket by the Rev. Mr. Hemſted; Sheerhatch wood, and Everſholt in Bedfordſhire, by Dr. Abbot; Medley grove, Oxfordſhire, by Dr. Sibthorp; and Merley wood near Whiteham, Berks, by the late Mr. Iſrael Lyons. It is found in moſt parts of Europe, from Sweden and Denmark to the South of France and Italy; alſo in Siberia.]

4. Root woody, creeping. Stems trailing, three feet long, their lower part becoming more woody towards autumn but dying to the root in winter. Leaves compoſed of ten pairs of ovate acute-pointed leaflets. Flowers diſpoſed in ſhort axillary ſpikes; each containing for the moſt part, ſix pale-blue flowers, which appear in july, and are ſucceeded by ſhort ſmooth pods, like thoſe of Lentils, including three or four round ſeeds which ripen in autumn.

[Native of Denmark, Germany, Auſtria, the South of France, &c.—Cultivated in Chelſea garden, in 1711 [t].

5. Root perennial, creeping. Stems two, three or four feet high, and even more when climbing on buſhes; quadrangular, ſlender, weak, ſtriated or grooved; ſlightly hairy, brittle and ſnapping when broken. Branches numerous, ſhort, alternate, from the axils of the upper leaves. Leaves alternate, very long, conſiſting of eight, ten or twelve pairs of leaflets, and terminated by a long branched and very curling tendril. Leaflets oftener alternate than oppoſite, more or leſs hoary on both ſides with ſilky hairs, commonly rounded at the end and terminated by a ſhort point. At the baſe of each leaf is a pair of ſmall villoſe ſemiſagittate, acute ſtipules, moſt frequently entire, but occaſionally toothed. Peduncles the length of the leaves, angular, hairy; bearing numerous, cloſely imbricate, rather drooping flowers, on one ſide of the common peduncle. The two upper teeth of the calyx extremely ſhort, the loweſt longeſt, blueiſh. Corolla has the ſtandard emarginate, reflexed, without any ſharp point in the notch, of a violet or blueiſh purple colour, ſtriped with veins of a deeper colour: wings cloſing: keel whitiſh marked on each ſide at the tip with a deep-violet ſpot. Style hairy all round. Legume half an inch long, pale brown, ſmooth, flattened on each ſide; containing four or five globular, black ſeeds, the ſize of a lentil.

Native of Europe and Barbary. Common with us in hedges and among buſhes, eſpecially in a black boggy ſoil on a gravelly bottom, about oſier-grounds. In ſuch places the denſe long ſpikes of purple flowers are moſt conſpicuous. In open paſtures and fields it is found of a much lower ſtature. It flowers from july to ſeptember; and is eaſily diſtinguiſhed by its leaves being covered with a fine ſilky down, giving them a manifeſt whiteneſs; and the flowers being of a rich deep-purple colour, growing in long racemes and thickly crowded together: the whiteneſs however is moſt manifeſt in ſuch plants as grow in dry expoſed ſituations.

Dr. Plot, in his hiſtory of Staffordſhire, ſays that this, and the ſylvatica or wood Vetch, advance ſtarved or weak cattle, above any thing yet known. Theſe perennial Vetches yield ſuch abundance of food, that they ſeem to deſerve the notice of agriculturiſts. But it is well obſerved in Engliſh Botany, that to gather from their native ſituations would be impracticable, ſo firmly do they cling to their neighbours; and if cultivated, they would probably choak themſelves for want of ſupport [u].]

Mr. Miller alſo ſays, that this and other perennial tares have been recommended to be ſown in fields as fodder for cattle, but as their ſtalks are ſlender and leſs ſucculent than thoſe of the common Tare or Vetch, it is doubtful whether theſe will anſwer the purpoſe of farmers to cultivate them: Their ſtalks trailing to a great length, if they have not ſupport, they will be ſubject to rot by lying upon the ground; and although their roots are perennial, yet as it is late in the ſpring before they ſhoot to a height ſufficient to cut for uſe, they do not come into uſe till there is a ſufficiency of other green food for cattle.

[6. This has the ſtature of the preceding. Leaflets commonly fourteen, very narrow, and the pairs diſtant. Peduncles axillary, three times as long as the leaves, ſtriated. Flowers ten or twelve, ſubſeſſile, very remote, three times as big as thoſe of V. Cracca, and purple. Legumes very wide [x].

Stem erect, angular, ſtriated, pubeſcent. Stipules forked, often toothed, awl-ſhaped. Leaflets ten to ſixteen, truncate, acuminate, pubeſcent; ſome increaſing from the baſe upwards, others equal. Flowers looſely diſpoſed all one way. Calyx-teeth ſharp, the three lower longer. Corolla blue, a little bigger than in V. ſativa: ſtandard elongated, obtuſe, erect, longer than the wings, with the margin bent back upwards: wings obtuſe, obverſely lanceolate, longer than the keel. Legume compreſſed, ſmooth, lanceolate, attenuated to both ends, acute, many-ſeeded. Flowers a little larger than in the European plant [y]: Native of France, Switzerland, Piedmont, and Mount Atlas.

Digitized by Google

Desfontaines has a ſpecies which he names V. polyphylla; but ſuſpects may be a variety of V. Cracoa. He found it in hedges about Algiers, and refers V. orientalis multiflora incana, anguſtiſſimo folio, *Tournef. cor.* 27. to it.—Stem ſtriated, erect, ſcarcely pubeſcent. Leaflets ſixteen to twenty-two, linear-lanceolate, mucronate, villoſe; the hairs very ſhort and preſſed cloſe. Stipules two-parted, lanceolate, acute. Peduncles axillary, twice as long as the leaf, ſtriated. Flowers like thoſe of V. Cracca, but larger and paler; racemed, all directed one way, crowded, ſubſeſſile, nodding.

7. Root annual. Stem grooved. Leaflets ſix pairs, ſcarcely retuſe, terminated by a point, ſubvilloſe. Stipules lanceolate, very narrow. Flowers five or ſix on a peduncle, very ſmall and dark purple. Legumes nodding, compreſſed, containing five ſeeds. Native of the Levant [z]. Introduced in 1773, by John Earl of Bute. It flowers in june and july [a].

8. Root biennial. Plant very tall, above twelve feet high. Leaflets rolled in [b]. Legume like that of piſiformis, but narrower, and attenuated into the peduncle. Seeds globular, dirty yellow ſpotted with black [c].]

According to Mr. Miller, the ſtalks riſe only five or ſix feet high; and the leaves are compoſed of five or ſix pairs of leaflets, on footſtalks deeply furrowed. The flowers are produced in axillary ſpikes, upon long peduncles; they are of a light blue colour, appear in july; and are ſucceeded by ſhort compreſſed pods, containing three or four round ſeeds, which ripen in autumn.

Native of Siberia, and promiſes fairly to become a uſeful plant for fodder, the ſtalks growing to a great length, and being well furniſhed with leaves: they do not decay in autumn, but continue green through the winter, in defiance of the moſt ſevere froſt; ſo that in february and march, when there is often a ſcarcity of green feed for ewes and lambs, this may be of great ſervice.

[Cultivated in 1759, by Mr. Miller [d].

9. The whole plant very ſmooth. Stem ſcandent, ſtriated. Leaflets ten or twelve, on ſhort petioles, alternate. Peduncles axillary, angular. Flowers numerous, all on one ſide, pedicelled, nodding. Calyx-teeth minute, the three lower acute and longer, the two upper very ſhort. Corolla pale blue, the ſize of thoſe in V. ſepium, or ſcarcely bigger. Legume lanceolate, compreſſed, containing many ſeeds.—It is allied to the preceding, but differs in having the leaflets truncate at the top, and the ſtipules toothed. Native of Barbary, in hedges near Arzeau [e].

10. Root annual. Corollas of a very deep red colour, with the apex of the keel black [f].

Firſt found by Tournefort on the Hieres iſlands, off the coaſt of France.

11. Annual. Stem four-cornered, ſtriated, villoſe. Leaflets twelve to eighteen, villoſe, obtuſe, acuminate, ſubpedicelled. Petiole angular, hirſute, cirrhoſe at the end. Stipules large, ſemiſagittate, acute, often toothed on one ſide of the baſe. Peduncles axillary, length of the leaf. Flowers nodding. Calyx-teeth briſtle-ſhaped, twice or thrice as long as the body of the calyx. Corolla ſmooth, very dark purple at the tip, the ſize of V. ſepium. Hairs on the legume ſhort, very cloſe, rufeſcent. Quite different from Hermann's plant, which is cultivated in the Paris garden. Hermann's figure repreſents the leaves ſharper and ſmaller, the peduncles few-flowered, and the calyxes obtuſe without the briſtle-ſhaped teeth. The plant here deſcribed grows wild in Iſles d'Hieres, was gathered there by the late Dr. John Sibthorp, who gave a ſpecimen of it to Monſ. L'Heritier, in whoſe herbarium it is, under the name of V. benghalenſis. But if it be really that ſpecies of Linneus, Hermann's name ought to be excluded. Linneus's diagnoſis however does not agree with the plant found by Sibthorp or Desfontaines, which has more numerous flowers, the ſtipules not entire but toothed, and the legumes not nearly erect but pendulous. Monſ. Desfontaines gathered it near Algiers [g].

12. The whole plant hoary with a woolly nap. Stem herbaceous, erect, a foot high and more, four-cornered, ſomewhat ſtriated. Lower leaves unequally pinnate; upper with a ſubcirrhoſe thread. Leaflets five to twenty-two or twenty-three alternate, ſome oppoſite, ſeſſile. Flowers in looſe ſpikes, all one way, blue. Calyx ſubcampanulate, gibbous above, with the two upper teeth ſhorter and converging. Wings of the corolla as long as the ſtandard: keel ſhorter. The ſingle filament connate into the ſheath towards the middle, but looſe at the baſe. Legume almoſt boat-ſhaped, compreſſed, tomentoſe. Seeds three or four, roundiſh. Native of Mount Libanus, towards the top. Annual [h].

13. Root annual. Stems various in ſize, weak and procumbent if the tendrils meet with nothing to cling to, but ſupporting one another tolerably well when ſown thick enough, angular and grooved, as are alſo the common foot-ſtalks of the leaves. The herb is more or leſs pubeſcent. Leaves terminated by a bifid or trifid tendril. Leaflets about ſix pairs, ſome oppoſite others alternate, varying much in form and breadth, moſt commonly retuſe, but ſometimes, at leaſt the upper ones elliptic-lanceolate, terminated by a point. Stipules in pairs, ſemiſagittate, more or leſs toothed, having a depreſſed mark on the outſide, which looks as if it were made with a hot iron, and varies in colour from black to brown, and even yellow. Flowers ſolitary or in pairs, ſubſeſſile, reddiſh purple of different ſhades. Calyx-teeth nearly equal. Legumes more generally horizontal than erect [i]; oblong, two inches long, compreſſed a little, ſwelling where the ſeeds lie; ſeven-celled, being divided by very thin partitions but permanent. Seeds ſix or ſeven irregularly round, turgidly lensſhaped, brown and ruſt colour variegated, faſtened to the ſtrait ſuture by a thread which is forked at the tip [k].

Native of Europe, Barbary and Japan, in paſtures and corn-fields. In dry ſoils it has a procumbent ſtem, ſharper leaflets, the flowers moſtly ſolitary, and the ſtipules ſpotted but obſcurely. It varies alſo in the colour of the pods, and of the ſeeds from black to brown and white [l]. The figure in Engliſh Botany from a wild ſpecimen, and that in Flora Ruſtica from a cultivated one, appear ſo different, that they would ſcarcely be recognized for the ſame ſpecies, if we had not every reaſon to ſuppoſe them both to be accurate repreſentations of individuals, and if we did not know that this plant varies much in the leaves.

β. The variety noticed above is not uncommon in hedges among buſhes and graſs, in a barren ſandy ſoil. It is the lathyroides α of Hudſon, and ſeems to be the common variety of ſativa mentioned in Withering, and which Mr. Woodward ſays may be traced through all its ſtages from its ſmalleſt ſize, up to the largeſt plants of this ſpecies. Dr. Withering deſcribes the ſtems as ſcored and undivided, the tendrils as three-cleft, the leafits of the lower leaves heart-ſhaped, two or three pairs, thoſe of the upper four or five pairs, linear blunt at the end, the mid-rib lengthened out into a thorn-like point, corolla purple, ſeeds ten to twelve.

γ. This variety was noticed by Bobart on Shotover hill. Dr. John Sibthorp found it in the ſame place, and in Stow wood. Sir Thomas Gery Cullum obſerved it at Weymouth. Dr. Withering, in the lanes in the vallies of Dartmoor. Dr. Smith among ſhort graſs in Richmond gardens. It commonly grows in a chalky or gravelly ſoil, and is the lathyroides β of Hudſon. The flowers are ſomewhat larger, handſomer, and of a deep red colour, the legumes longer and black. Dr. Sibthorp diſtinguiſhes it as a ſpecies under the name of V. anguſtifolia, with the following ſpecific character—Legumes ſubſeſſile ſubbinate ſpreading, lower leaflets obcordate emarginate and mucronate, upper linear. Roth alſo, (fl. germ. 310.) has adopted the ſame idea.

V. ſativa is ſo called becauſe it has been long cultivated under the names of Tares and Vetches, (provincially Fitches) for the ſeeds, which are an excellent food for pigeons, and alſo for green feed of horſes, kine and ſheep, particularly for ſoiling horſes. For this

[z] Desfontains. [a] Linn. ſpec. [b] Hort. kew. [c] Lin. ſpec. and ſyſt. [c] Gærtner. [d] Hort. kew. [e] Desfontaines. [f] Lin. ſpec. [g] Desfontaines.

latter purpoſe, and as a meliorating crop, it has obtained very much within a few years paſt [m].

Tares are ſaid to produce good milk and butter, only they dry cows when they are too near maturity, and are therefore beſt for horſes in their advanced ſtate.

They are very uſeful in may, or for keep till midſummer, at which time, in a dry ſeaſon, thin ſoils are apt to burn up.

Winter tares are admirable for ſoiling beaſts, and to ſpare graſs: for if bullocks are turned to graze as ſoon as the graſs riſes in the ſpring, they keep the ground ſo bare, that if a hot ſeaſon enſues, it is burnt up, and the farmer has no reſource, but to turn them to hay a ſecond time.

By an experiment of Hutcheſon Mure, Eſq. eighty-one beaſts eat juſt half an acre of tares every day, and throve on them very well. It appeared that a beaſt of fifty ſtone weight got one ſtone a month on ſtraw in the winter; two ſtones and a half by the firſt graſs in the ſpring; three ſtones a month by graſs in ſummer; and above four ſtones a month by ſoiling in tares.

Spring tares with oats ſown early in march, and cut green for horſes in july, are good for cleaning light land, and preparing it for Wheat or Rie.

Winter Tares ſown with a little Rie in autumn for ſoiling, give time to deſtroy weeds by tillage till autumn: or they may produce a ſecond crop; turneps if it be deſigned for ſpring corn: but the land ſhould be manured for the tares if it be not very rich [n].

Nine acres of Tares ſown in drills, and five or ſix broad-caſt, fed twelve and ſometimes thirteen draught horſes, during part of the ſpring, and all the ſummer, in all about four months, except ſome few beans and bran, when they worked hard. Five milch cows alſo, and a bull, were fed with theſe tares in the farm-yard. The milk of the cows was greatly increaſed in quantity, and the horſes were healthy [o].

Spring Tares are grown in Northumberland principally for cutting as green food for horſes, to ſupply the vacancy between the firſt and ſecond cutting of red clover uſed for the ſame purpoſe [p].

Winter Tares are ſown in Kent, either to feed off with cattle and ſheep in april, or to mow for ſoiling in may. The ſpring Tares, either for ſoiling in july and auguſt, or to ſtand for a crop of ſeed.

Sowing winter and ſpring tares to fold ſheep on in the ſpring and ſummer, is reckoned among the greateſt improvements on the ſtrong ſoil of the weald of Kent, where turneps hardly ever anſwer. It is ſaid that they make an excellent tilth for wheat; but this is diſputed [q].

Many farmers in Middleſex, eſpecially near London, grow a few acres of tares, for ſoiling horſes and feeding milch cows, and the culture of them has been extended every year, from their importance having been better underſtood. Mr. Middleton, in his view of the Agriculture of that county, obſerves that they may be made the principal means of enabling the arable farmer to ſupport as much live ſtock as the grazier. For during the time they occupy the ground, they produce more green food of the beſt quality than Romney-marſh or Pevenſey-level, and the ground may be cleared of them in the month of june, in ſuch time as to admit of loamy ſands producing a crop of clean turneps in the ſame year, and of clayey loams being prepared for and ſown with wheat. They ſupport cattle, will make both ſheep and bullocks of every ſize and breed fat, ſuit every ſituation, and will flouriſh on all ſoils. They do not depend on a market, and above all, they manure the land fit for the immediate reception of turneps; whereby a ſucceſſion of green crops can be kept up, that would fat a very increaſed quantity of live ſtock, and be the means of raiſing, in ſituations the moſt diſtant from towns, an abundance of dung. A judicious combination of tares with turneps, clover and ſaintfoin, may be the means of rendering poor ſheep-walks, downs and waſtes, of from ten to thirty times their preſent value to the community.

[m] Idem. [n] Young's Annals 1. 128. 2. 347. 360. 3. p. 5. 6.
[o] Tranſ. arts. 8. 59. [p] Survey, p. 78. [q] Survey, p. 94.

Winter tares begin to flower in may, and from that time ſtock may be advantageouſly ſupported on them, till the flowers fall off, and pods begin to form: then all that are left may be made into hay, or left for ſeed. If the land was dunged and the ſeed good, there will probably be twelve tons of green food on an acre; which will make three tons of excellent hay, provided the ſeaſon will admit it to be well cured. But in a wet or uncertain ſeaſon it is far better to uſe the whole crop green; and by ſo doing, the ſtock will be taken off the graſs land long enough to allow of its being mown for hay; and by the time the cattle have conſumed the green tares, the after-graſs will be ready to receive them.

Spring tares produce a lighter crop, and are ſubject to ſome riſk from a dry ſummer, but coming a fortnight later, they will make a ſucceſſion of green food all the ſummer.

The moſt adviſeable method of giving them to cattle, is to mow the Tares off the firſt half acre, and to carry the produce into the ſtables, cow-houſes and fold-yards, or on to poor land to be there conſumed by the ſtock. Then to hurdle off the growing Tares from ſuch cleared ground, into which put the ſtock, feeding them in racks, and removing the hurdles with the racks daily to the edge of the growing Tares; by which means the land will be manured uniformly and all the urine depoſited in the ſoil. Or they may be fed through rack-hurdles, made the ſame with the common ones, only leaving the middle rail out, and nailing upright pieces acroſs, at proper diſtances, to admit the ſheep to put their heads through. A ſwath being mown in the direction you wiſh to plough the land, a ſufficient number of theſe hurdles, allowing one to five ſheep, are ſet cloſe to it: at noon the ſhepherd mows another ſwath, throwing it to the hurdles, and the ſame at night: next morning, a ſwath being firſt mown, the hurdles are again ſet; thus mowing them once in the twenty-four hours, the Tares are eaten clean off, and the land is equally benefited.

Mr. Davis of Beddingham in Suſſex ſays, that not one tenth of his ſtock could be maintained without Tares; that they keep more ſtock than any other plant whatſoever; that hogs may be foiled upon them, as well as horſes, cows and ſheep, without any other food; that one acre of Tares will maintain four horſes in much better condition than five acres of graſs; and that upon eight acres he has kept twelve horſes and five cows for three months, and no other food given them [r].

Tare or Vetches vary in ſome degree in cultivation, and hence have different names among agriculturiſts—as Gore-vetch, Pebble-vetch, Winter-vetch, Rath-ripe vetch, Gout-vetch, &c. The two laſt are the ſame with the Spring-vetch, between which and the Winter-vetch, it is not agreed whether there be any real difference, grounded on the nature of the plants themſelves, or whether the difference may not be owing merely to the time of ſowing.

With a view to decide this queſtion, two experiments were made by the late Rev. Mr. Laurents of Bury.

September 30, 1783, he ſowed ſeeds both of the winter and ſpring Tare near one another in the ſame ſoil and expoſure, and covered both an inch deep with crumbled mould. The weather proving mild, the Spring Tare ſoon made its appearance, and two days after the winter Tare came up. They were both in a vigorous and thriving condition, when a froſt came on about the middle of december, and continued for ſome weeks. When a thaw took place, the ſpring tare was lying on the ground, ſlimy and putrified to the very root. The winter tare had received no damage, grew up afterwards, and was ripe before the middle of auguſt.

March 6, 1784, both ſorts were again ſown. Near a week later than the winter tare of the autumnal ſowing, the ſpring tare of the vernal ſowing arrived at perfect maturity. But the winter tare of the vernal ſowing was mildewed, nor did a ſingle pod of it ripen.

[r] Middleſex Report, 199, 201—203.

Digitized by Google

From theſe two circumſtances there appears a material difference in the conſtitution, if we may ſo call it, of the two tares in queſtion. Not to ſay any thing of a trifling difference in the colour and ſize of their ſeeds, the only viſible mark of diſtinction ſeems to be a diſparity in the firſt leaves of the upright ſtalks, which in the ſpring tare are elliptic and rounded or notched at the end, but in the winter tare lineat and drawn to a point. The leaves on the branches, which afterwards iſſue below, and in time form the bulk of the plants, are the ſame in both vetches.

But whatever the difference may be, it is evident that the ſeeds of the two ſorts ought to be kept ſeparate, ſince each ſown out of its proper ſeaſon is found not to proſper. Mr. Laurents, wiſhing to compare with our winter tare, that which is cultivated in the Pays de Caux, under the name of hyvernache, ſearched almoſt every ſhop in Rouen, where it was likely to be found, in vain. The reaſon aſſigned was, that the time of ſowing it was over. So exact a proportion between the wants of the farmer, and the ſtock at market, ſtruck him as a caſe ſomewhat remarkable, the ſolution of which he conjectured to be, that after the autumnal ſowing, the remains of the hyvernache were thrown in among the other tares. This, it is to be feared, is not an uncommon practice among our ſeedſmen, not only with tares, but with other ſeeds: and may account for what Mr. Laurents obſerved in ſome fields after the froſt, that there were patches of ſomething in a ſtate of putrefaction, reſembling the dead tares in his garden.

Mr. Laurents alſo remarked, that ſome winter tares, ſelf-ſown in auguſt, were ſo forward as to ſuffer from the ſeverity of the winter, more than what he had ſown in his firſt experiment. Hence it appeared to him, that if the lower ſhoots are coming out before the winter ſets in, they are ſufficiently forward, and will ſtand ready to ſtart at the genial ſummons of returning ſpring [s].

A crop of winter tares, which I ſowed laſt month, now, (november 15th, 1804) correſpond exactly with Mr. Laurents's figure of the ſpring Tare.

We cannot aſcertain when Tares were firſt introduced, becauſe they ſeem to have been cultivated, before we have any printed or written regiſters on the ſubject of agriculture. Perhaps from the time of the Romans, who cultivated them much. They are mentioned by Fitzherberd, under the name of fitches or fytches, as being ſown with beans and peas in one crop [t]: and ſeem anciently to have been cultivated only for the ſeed, probably to feed pigeons. Little is ſaid about them by the improvers under the Commonwealth. Hartlib ſays, that in Kent ſometimes Tares were ſown in his time, which, when the cattle had eaten a little of the tops, they turned in with very good improvement for their ground [u].

Worlidge, in 1681, ſays that the Winter and Summer Fetch or Citch are much ſown in ſome places, and to a very conſiderable advantage; and that they are a good, ſtrong and nouriſhing food to cattle, either given in the ſtraw or without [x].

Ray, in 1686, informs us, that the Common Tare or Vetch, was then ſown almoſt all over Europe; that it was chiefly uſed in England, mixed with peas and oats, to feed horſes; but that it was ſometimes ſown ſeparately for ſoiling cattle, and was reputed to cauſe milch cows to yield much milk [y].

Mr. Liſle, at the beginning of the eighteenth century, has much upon the ſubject of Vetches [z].

14. Root annual. Sometimes it has no tendrils [a].

Native of Denmark and Norway, France and Britain. What Hudſon, &c. have taken for this plant, is a variety of V. ſativa.

Stems procumbent, divaricating, numerous. Theſe, with the leaves and ſtipules ſlightly hairy. Leaflets two or three pairs, oppoſite, obcordate, but towards the top of the plant ſometimes lanceolate and narrowed. Stipules ſemiſagittate, moſtly quite entire, rarely if ever ſpotted. Flowers ſubſeſſile, ſolitary, ſmall, blueiſh purple. Legumes erect, very ſmooth, containing ſeveral cubic ſeeds, rugged with minute tubercles.—It is very diſtinct from the varieties of the preceding, by its ſmooth even pods, tubercled ſeeds, ſimple tendrils commonly very ſhort and in a manner abortive, and not more leaflets than ſix [b].

The true leading characters of this ſpecies, ſays Mr. Woodward, are, the corolla being ſcarcely longer than the calyx, the ſeeds cubic, and the tendril never branched.

Root ſmall, fibrous, annual. Whole plant hairy except the pods. Stems ſeveral, a foot high or leſs, weak, trailing. Leaflets four to ſix, never more, oppoſite, the upper ones moſtly lanceolate. Tendrils never branched. Stipules half-arrow ſhaped; the upper lanceolate, narrow, pointed, Flowers ſmall, blueiſh purple. Legumes upright, ſmooth, dotted. Seeds cubic [c].

Dr. Stokes remarks, that the ſtipules are not ſpotted.

Dr. Abbot obſerves, that the root is ornamented with garnet-coloured tubercles; that the ſtipules have not the burnt ſpot; and that there are two or three pairs of leafits, without an odd one or tendrils, ending in a point.

The figures in Engliſh Botany, Flora Danica, and Kniphoffius, have no tendrils; in thoſe of Rivinus and Jacquin, the tendrils are repreſented as unbranched [d]. Moriſon's figure is a very bad one.

No Britiſh plant has been leſs underſtood than this Vicia. That it is Tournefort's plant, and conſequently Ervum ſolonienſe of Linneus, which he took up from that author without having it in his own collection, appears from Tournefort's herbarium at Paris. That it is the true V. lathyroides, is certain from the Linnean herbarium.

Our plant is found on dry graſſy banks, and in fallow fields on a gravelly ſoil, flowering early in may, and ſcarcely to be met with after the month of june. It was found by Mr. James Sherard and Mr. Rand on chalky banks near Greenhithe in Kent. Mr. Pitchford found it about Norwich; Mr. Dickſon in the dry parts of Hyde Park; and Mr. Lightfoot in King's Park, Edinburgh.—There is a variety with white flowers [e].

15. Root perennial, long, divided at the top, among the looſe pebbles where it grows, into ſeveral diffuſe, angular, ſmooth, ſtriated, ſubflexouſe, leafy ſtems, often two or three feet long, but little branched. Some of the branches are always ſubterraneous, producing colourleſs condenſed *gemmæ* rather than flowers, which however form ſeeds as in *Lathyrus amphicarpos*, and ſome other vetches. Leaves compoſed of numerous, (three to five pairs,) oppoſite or alternate, (moſtly alternate, *Woodw.*) elliptic-lanceolate, (or oblong,) pointed or bluntiſh, ſometimes retuſe leaflets, which are hairy beneath, with a branched (bifid or trifid) tendril at the end of their common footſtalk. Stipules ſmall, deltoid, ſubſagittate, generally ſtained externally, more or leſs deeply, with a blackiſh-red hue; ſome of them however are green. Flowers ſolitary, almoſt ſeſſile. Calyx tubular. Corolla pale yellow, but generally more or leſs ſtreaked and ſtained with a blueiſh gray or purple; very rarely all over gray: ſtandard quite ſmooth. Legumes reflexed, broad, compreſſed, clothed with ſhort hairs ariſing from ſmall tubercles. Seeds five or ſix, roundiſh, ſmooth, in a young ſtate bitter and aſtringent.

The late Mr. Humphrey of Norwich found this plant many years ago on the beach at Orford in Suffolk, on the ſide next the river, about a mile from the haven's mouth. It has ſince been met wirh at Aldborough, by the Rev. Mr. Burroughes. At Weymouth by the Rev. Mr. Baker and A. B. Lambert, Eſq. in Auguſt 1795. Certainly found in a chalk-pit on the ſide of Glaſtenbury Tor-hill, by Mr. D. Turner, in 1799. In Mearnſhire, North Britain, by Profeſſor Beattie [f].

Native of ſeveral other parts of Europe, the Levant and about Algiers.

16. Root perennial. Plant generally taller and

Digitized by Google

more upright than the preceding, which it otherwiſe very nearly reſembles in habit and leading characters. The flowers are generally yellow (lemon-coloured) ſtreaked a little with pale purpliſh red, not varying to gray or purple: they are eſſentially characterized by the back of their ſtandard being hairy; it is alſo red at the baſe. Another mark of this ſpecies is the ſtipules being entirely green. The leaflets vary greatly in ſhape, as in moſt of this genus, but are always more obtuſe and emarginate than thoſe of V. lutea: they are hairy, as in that ſpecies, as well as the pods; which contain five ſeeds [g].

Calyx ſhort, unequal; teeth awl-ſhaped: the whole ſlightly villoſe. Corolla pale yellow; ſtandard heart-ſhaped, entirely covered with ſhort hairs on the back, but moſt conſpicuous at the baſe; within ſmooth and veined: wings oval, entire, hooked, and terminating in a narrow claw adhering to the keel, and ſhorter than the keel, which is greeniſh.

Gathered by Mr. Sole and A. B. Lambert, Eſq. in june 1797, on Glaſtenbury Tor-hill, Somerſetſhire, as mentioned by Ray. But it could not be found there in 1799, by Mr. D. Turner. What Hudſon took for it at Weymouth, is the lævigata [h].

Native of France, Piedmont and Barbary.

17. Root perennial. It has the habit of V. lutea but the ſtems are only from ſix to twelve inches long, upright, and always much leſs diffuſe. Leaves and whole plant entirely ſmooth. Leaflets elliptic-lanceolate, terminated by a little point, ſcarcely ever retuſe. Stipules green or pale brown. Flowers like thoſe of the lutea, but their calyx-teeth are generally more equal in length. The corolla is for the moſt part leſs yellow, and ſometimes quite blue, but both are extremely variable in that reſpect. The pods are even and quite ſmooth in every ſtage of their growth, of a brown colour, and contain rarely more than five ſeeds.

Gathered on the beach at Weymouth, by the Rev. Mr. Baker, in auguſt 1792. Frequently taken for the hybrida, and ſometimes for the bithynica [i].

18. Root annual. Stems ſlender and weak. Leaflets linear, truncate, four or five pairs. Stipule two-toothed, with a violet ſtain below the upper ſegment. Flowers ſolitary, large, of a duſky violet colour, with the ſtandard deeply notched. Pods pendulous, wide, flatted, marked tranſverſely on the outſide with purpliſh ſtripes, and containing four or five (ſometimes ſix or ſeven) ſeeds [k].

Native of France and Piedmont. Introduced in 1779, by Monſ. Thouin. It flowers in july [l].

19. Root perennial. Stems climbing by tendrils, two feet high, grooved, little branched. Leaves many-paired, terminated by a branching tendril. Leaflets ovate, obtuſe, ſometimes emarginate, ſomewhat hairy, the outer ones gradually ſmaller. Stipules creſcent-ſhaped, ſharply toothed. Flowers commonly in fours, on very ſhort pedicels, all directed one way, dark blue purple. Calyx hairy. Legume nearly erect, brown, dotted, ſmooth. Seeds globular, even [m].

Leaflets ovate with a projecting point, or ovate-lanceolate, oppoſite. Stipules ſemiſagittate, ſmall, acute. Flowers three or four in the axils of the upper leaves, on very ſhort pedicels. Calyx very hairy, with nearly equal ſegments. Flowers dirty purple; ſometime white [n].

According to Linneus, the leaves are doubled together, and the flowers are in racemes (three or four) ſhorter than the leaves.

Villars ſays, the ſtems are a foot and half high, and ſupport themſelves though weak. Leaflets oval, twelve or fourteen, diminiſhed in ſize. Flowers pale duſky red, inclining to carnation. Pods ſtraight, linear, oblong and rounded, a little villoſe.

Native of Europe, in woods, hedges and buſhy paſtures; flowering in may and june.

It ſhoots earlier in the ſpring than any plant eaten by cattle, vegetates late in the autumn, and continues green all winter. But it is difficult to collect the ſeeds, as the pods burſt and ſcatter them about, and moreover hardly a third part of them will vegetate, being made the nidus of an inſect. A patch ſown in drills in a garden was cut five times in the courſe of the ſecond year, and produced at the rate of twenty-four tons on an acre of green food; which when dry would weigh near four tons and a half. Though palatable to all kinds of cattle, it may be difficult to cultivate it on a large ſcale, the ſeeds being generally devoured by the larvæ of a ſpecies of Attelabus, which larvæ are the prey of a ſpecies of Ichneumon [o].

20. Root perennial, branched. Stems ſeveral, climbing by tendrils, branched, angular, grooved, ſmooth. Leaves two-paired, terminated by elongated branched tendrils: leaflets large, elliptic-lanceolate, acute, ſomewhat hairy beneath. Stipules large, ſemiſagittate, unequally toothed; teeth divaricating, acute. Flowers ſolitary, peduncled; the peduncles various in length, very ſeldom two-flowered. Teeth of the calyx ciliate. Standard of the corolla large, of a leaden purple colour: wings and keel whitiſh. Legume erect, bay-coloured, hairy and rugged. Seeds five or ſix, globular, ſmooth, black, and aſh-colour variegated [p].

Dr. Withering remarks, that the ſeeds are protuberant; the ſtandard and keel of the corolla red purple, and the wings yellowiſh.

Stems angular. Leaflets in two pairs, broad-lanceolate. Stipules much toothed. Flowers ſolitary; with a calyx the length of the peduncle. Standard of the corolla violet: wings whitiſh. Legume compreſſed, ovate-oblong, villoſe. Seeds about ſix. The bearded ſtigma, and ſtipules with a glandular pore beneath, evince this to be a Vicia [q].

Native of the county of Nice, Italy, Bavaria, and England.—Found near Doncaſter by Mr. Tofield, upon the authority of his herbarium, now in the hands of Dr. Younge of Sheffield:—in woods near Cliſton upon Teme, Worceſterſhire, by Dr. Stokes:—in the Iſle of Purbeck, by Mr. Hudſon:—in Portland Iſland, half a mile to the left of the ferry, on looſe ſand-banks, by Mr. Stackhouſe:—and in a field half way between Weymouth and Portland ferry, near the ſea, by A. B. Lambert, Eſq. It flowers in july and auguſt [r].

21. Root annual. Stem erect, angular, ſtriated. Leaves pubeſcent: leaflets ovate, blunt with a very ſhort point; two on the lower leaves, four or ſix on the upper ones. Stipules large, roundiſh, toothed, mucronate. Flowers ſolitary, ſeſſile or on ſhort pedicels. Calyx half-five-cleft, with lanceolate, acute ſegments. Legumes compreſſed, villoſe, acute, containing many ſeeds [s].

Linneus remarks, that the leaves are doubled together, as in V. ſepium, not rolled in, as in moſt of the ſpecies; that the peduncles are one-flowered in barren, three-flowered in fertile ſoils; and that the corolla is very dark purple [t].

Native of France and Barbary near Algiers among corn.—Cultivated in 1597, by Gerarde. It flowers in june [u].

22. Root annual. Stem upright, about two feet high, to three or four in the larger garden varieties, thick, angular. Leaves without tendrils. Leaflets about three pairs, ovate-oblong, tomentoſe, convoluted. Flowers ſeveral together in the axils, white with a black ſilken ſpot in the middle of the wings. Legumes thick, roundiſh, ſtraight, pointed, very woolly within, containing ſeveral large ovate, flatted ſeeds. In the Kew catalogue, it is ſaid to be a native of Egypt. Linneus, from Lerche, affirms that it is found wild not far from the Caſpian ſea, on the confines of Perſia. It has been cultivated time out of mind both in fields and gardens, not only over great part of Europe, but in China, Japan, &c.

Varieties of the Garden Bean.]

1. The Mazagan Bean is the firſt and beſt ſort of early

V I C

early Beans at preſent known; they are brought from a ſettlement of the Portugueſe on the coaſt of Africa, juſt without the Straits of Gibraltar; the ſeeds of this ſort are ſmaller than thoſe of the Horſe Bean; and as the Portugueſe are but ſlovenly gardeners, there is commonly a great number of bad ſeeds among them. If this ſort is ſown in october, under a warm hedge, pale, or wall, and carefully earthed up when the plants are advanced, they will be fit for the table by the middle of may. The ſtems of this ſort are very ſlender, therefore if they are ſupported by ſtrings cloſe to the hedge, or pale, it will preſerve them from the morning froſts, which are ſometimes ſevere in the ſpring, and retard their growth; and by keeping them cloſe to the fence it will cauſe them to come forwarder than if this is neglected; theſe Beans bear plentifully, but they ripen nearly together, ſo that there are never more than two gatherings from the ſame plants; if the ſeeds of this ſort are ſaved two years in England, the Beans will become much larger, and not ripen ſo ſoon, which is called a degeneracy.

2. The next ſort is the early Portugal or Liſbon Bean, which appears to be the Mazagan ſort ſaved in Portugal, for it is very like thoſe which are the firſt year ſaved in England; this is the moſt common ſort uſed by the gardeners for their firſt crop, but they are not near ſo well taſted as the Mazagan; therefore when the Mazagan Bean can be procured, no perſon would plant the other.

3. The next is the ſmall Spaniſh Bean; this will come in ſoon after the Portugal ſort, and is rather a ſweeter Bean, therefore ſhould be preferred to it.

4. Then comes the broad Spaniſh, which is a little later than the other, but comes in before the common ſorts, and is a good bearer and therefore is frequently planted.

5. The Sandwich Bean comes ſoon after the Spaniſh, and is almoſt as large as the Windſor Bean; but, being hardier, is commonly ſown a month ſooner; this is a plentiful bearer, but not very delicate for the table.

6. The Toker Bean, as it is generally called, comes about the ſame time with the Sandwich, and is a great bearer; therefore is now much planted, though it is a coarſe Bean.

7, 8. The white and black Bloſſom Beans are alſo by ſome perſons much eſteemed; the Beans of the former are, when boiled, almoſt as green as Peas; and being a tolerable ſweet Bean, renders it more valuable; theſe ſorts are very apt to degenerate, if their ſeeds are not ſaved with great care.

9. The Windſor Bean is allowed to be the beſt of all the ſorts for the table; when theſe are planted on a good ſoil, and are allowed ſufficient room, their ſeeds will be very large, and in great plenty; and when they are gathered young, are the ſweeteſt and beſt taſted of all the ſorts; but theſe ſhould be carefully ſaved, by pulling out ſuch of the plants as are not perfectly right, and afterward by ſorting out all the good from the bad Beans.

This ſort of Bean is ſeldom planted before Chriſtmas, becauſe it will not bear the froſt ſo well as many of the other ſorts; ſo it is generally planted for the great crop, to come in june and july.

[Of the ſmall early varieties, there is one which is chiefly planted for curioſity: it is a dwarf, ſix or ten inches in height, with branches ſpreading like a fan, and flowers ſucceeded by ſmall pods, both in cluſters; whence it is called dwarf Fan or Cluſter Bean.

Of the middle-ſized later Beans, one now very commonly cultivated is the Long-podded Bean, a yard or more in height, a great bearer, the pods long and narrow, cloſely filled with oblong middle-ſized ſeeds. Of this there are ſeveral ſubordinate varieties, as the early, tall, Turkey, &c.

The white-bloſſomed Bean (n. 7.) is an anomaly, as to the flowers, having none of the black mark on the wings. The ſeed is ſemitranſparent, and having leſs of the peculiar bean flavour, when young, than any of the others, is by many perſons much eſteemed. It bears abundance of ſmalliſh, long, narrow pods, and the ſeeds are almoſt black when ripe.

Beſides this and the black (n. 8.) there is a red-bloſſomed Bean, with ſmalliſh pods and ſeeds, not near ſo palatable as that with white bloſſoms.

There are other varieties, but they are ſcarcely worth notice.]

Varieties of the Field Bean.

1. The common Horſe Bean. [Probably the original of all the varieties.]

2. The Tick Bean, lower in ſtature, a more plentiful bearer, and ſucceeds better on light land. [Of this there are ſeveral ſubordinate varieties; as flat Ticks or May Beans, ſmall or Eſſex Ticks, and French Ticks. Some of the garden beans are taken into field culture in Kent; as the Toker, Windſor, Long-pod, Spaniſh or Liſbon, and Mazagan; beſides others cultivated only in ſmall quantities for ſupplying the London ſeedſmen.

Mr. Miller inſiſts that the Field Bean is a different ſpecies from the Garden Bean; but that is an idea deſtitute of all probability.

23. Root annual, whitiſh, branched, and, like thoſe of its congeners, furniſhed with tubercles: ſtem ſingle or double, acutely quadrangular; aſcendent at the baſe, and then upright; riſing to the height of about two feet: Stipules roundiſh unequally and very ſharply toothed: loweſt leaves binate, the remaining ones bijugate; the upper tri or quadrijugate, and generally terminated by a tripartite tendril: rib angular-ſtriate; leaflets ſubovate, obtuſe, ſharply tooth-ſerrate, pale-green, and very ſhortly foot-ſtalked: one of the laſt leaflets is often wanting, in which caſe the leaf has the appearance of a pinnated leaf terminated by an odd leaflet: the ſtem, edges, and ribs of the leaflets are furniſhed with fine hairs, ſcarcely viſible without a glaſs. The foot-ſtalks are few-flowered, and ſpring from the boſoms of the leaves. The flowers are of a moderate ſize and violet-purple. The legume is flat-compreſſed, and furniſhed on each ſide with white hairs. Native of the Euganian mountains, flowering in june [x].

24. Stem angular, ſlender, procumbent. Leaflets eight to twelve, very narrow, remote, alternate. Stipules very ſmall, ſemihaſtate, acute, ſimple or toothed. Peduncles axillary, filiform, one or two-flowered, awned. Calyx five-toothed. Corolla blue. Native of Algiers.

25, Allied to V. ſativa. Stem four-cornered, decumbent. Leaflets ten to fourteen, alternate, ſomewhat villoſe, mucronate. Stipules ſmall, acute, unſpotted. Peduncles ſolitary, twice or three times ſhorter than the leaf, one-flowered ſeldom two-flowered, having a ſhort ſpur below the flower. Calyx five-toothed ſmooth; teeth ſmall, acute. Corolla leſs almoſt by half than that of V. ſativa, more ſlender, lengthened out, pale blue. Legume compreſſed, ſmooth, containing from four to ſix ſeeds. Native of Algiers [y].]

PROPAGATION AND CULTURE.

2, 3, 4, 5. Theſe ſorts are propagated by ſeeds, which ſhould be ſown in autumn ſoon after they are ripe, for if they are kept out of the ground till ſpring, the ſeeds often fail, or at leaſt remain in the ground a year before they vegetate; they ſhould be ſown in the places where the plants are deſigned to remain, for they do not bear tranſplanting well. Theſe plants grow naturally in woods and thickets of buſhes, where their roots are ſcreened from the ſun, and their ſtalks furniſhed with ſupports by the buſhes, point out the places where the ſeeds ſhould be ſown, which ſhould be where they are ſheltered by ſhrubs. If three or four ſeeds are ſown on each patch, it will be ſufficient, for if one or two plants come up in each place it will be enough. When the plants come up, they will require no other culture but to keep them clean from weeds, and their ſtalks muſt be permitted to climb upon the neighbouring ſhrubs; for if they trail upon the ground, they will produce few flowers, and in wet ſeaſons the ſtalks will rot, ſo the plants will be rather unſightly.

[x] Jacquin. [y] Desfontaines.

Digitized by Google

A few of theſe plants may be allowed a place in large gardens, particularly on the borders of wood-walks, or in thickets of ſhrubs; where if they are allowed to climb up the branches, they will have a good effect during their continuance in flower.

8. This ſort is propagated by ſeeds, which may be ſown in the ſpring or autumn; and when the plants come up, they will require no other culture but to keep them clean from weeds; and if they are ſupported from trailing upon the ground, they will continue in verdure all the winter, and the following ſummer they will flower and produce ripe ſeeds.

If this plant is deſigned for feed, the ſeed ſhould be ſown in rows at four feet diſtance, and ſhould be dropped thin in the rows; for as the ſtalks ſend out many branches, and extend to a great length, ſo when the plants are too cloſe, the branches will intermix, and mat ſo cloſely together, as to rot each other by excluding the air. When the plants come up, they muſt be kept clean from weeds, which, while they are young, ſhould be performed with Dutch hoes, but afterward it may be done by the hoeing plough, which will ſave expence, and with this inſtrument the plants may be earthed up in the ſame manner as Peas and Beans, which will greatly ſtrengthen their ſtalks, and make them and the leaves larger and more ſucculent, ſo increaſe the quantity of feed. If this is practiſed as often as may be found neceſſary to deſtroy the weeds in ſummer, it will prepare the ground for any crop which may afterward be put upon the land; and as this will be in no danger of ſuffering from froſt, ſo it ſhould be preſerved till the ſpring, when there is a want of green feed for ewes, at which time it may be cut as it is wanted; but a part of the plants ſhould be permitted to ſtand for ſeeds, for thoſe which are cut, if they do ſhoot again, will flower ſo late in ſummer, that unleſs the autumn proves very warm, the ſeeds will not ripen; therefore it will be a better way to ſow a ſufficient quantity of ſeeds for this purpoſe in a ſeparate ſpot of ground, becauſe, when the other is cut, the ground may be ploughed for other crops; and if in mild ſeaſons there may be ſo great plenty of other green feed as not to want this, if the plants are ploughed into the ground, it will be a good dreſſing for other crops.

Vetches are generally ſown at two ſeaſons, one is in autumn, and the other early in the ſpring; but the beſt time is in auguſt, for the ſeeds which are ſown then will come up ſoon, and the plants will have time to get ſtrength before winter, ſo will be in leſs danger of ſuffering by froſt than thoſe which are ſown later, and will be fit to cut for feed much earlier in the ſpring, for it is then green feed is moſt wanted; and if they are deſigned for ſeed and not to be cut for fodder, thoſe early-ſown Vetches will come early into flower, and the ſeeds will be ripe early, ſo they may be cut and ſtacked in good weather; which is a great advantage, for thoſe which ripen late are often ſtacked or houſed wet, and then the ſeeds frequently ſprout in the mow, and are ſpoiled.

The uſual method of ſowing Vetches is in broad-caſt, ploughing them lightly in; in this way the common allowance of ſeeds for one acre of land is two buſhels, but there are ſome who ſow two buſhels and a half; this practice may do well enough for thoſe Vetches which are deſigned to be cut for fodder in the ſpring, but thoſe which are ſown with an intent to ſtand for ſeeds, will do much better if they are ſown in drills in the ſame way as is practiſed for Peas, and then leſs than half the quantity of ſeeds will be ſufficient; for the drills ſhould not be nearer to each other than three feet, that the hoe plough may have room to go between them, to deſtroy the weeds, and earth up the plants; for by this management they will produce a much greater crop, and ripen earlier in the ſeaſon.

Theſe drills ſhould be about the ſame depth as thoſe uſually made for Peas, and the ſeeds ſhould be ſcattered about the ſame diſtance in the drills. Theſe ſeeds ſhould be carefully covered as ſoon as they are ſown, for if they are left open the rooks will diſcover them; and when they once find the rows, if they are not carefully watched, they will entirely devour them. Indeed, theſe being ſown early in autumn, will be in leſs danger than thoſe which are ſown late, or in the ſpring, becauſe there is more food for rooks and pigeons in the open fields at this ſeaſon, and the plants will appear much ſooner above ground. The beſt time to ſow them is about the beginning of auguſt, for the rains which uſually fall about that ſeaſon, will bring them up in a ſhort time. Toward the latter end of october the plants will have obtained conſiderable ſtrength, therefore they ſhould be earthed up with the hoeing plough. This work ſhould be performed in dry weather, and in doing it care muſt be had to lay the earth up as high to the ſtems of the plants as poſſible, ſo as not to cover their tops, becauſe this will ſecure them againſt froſt. The whole ſpace of ground between the rows ſhould alſo be ſtirred, in order to deſtroy the weeds, which, if carefully performed in dry weather, will lay the land clean till march; at which time the crop ſhould be earthed a ſecond time, and the ground cleaned again between the rows, which will cauſe the plants to grow vigorous, and in a little time they will ſpread ſo as to meet, and cover the ſpaces; whereas thoſe ſown in the ſpring will not grow to half this ſize, and will be very late in flowering.

Some people ſow theſe Vetches, and when they are fully grown, plough them into the ground to manure it. Where this is deſigned, there will be no occaſion to ſow them in drills at this diſtance, nor to huſband them in the manner before directed; but in this caſe it will be the beſt method to ſow them in autumn, becauſe they will be fit to plough in much ſooner the following year, ſo that the land may be better prepared to receive the crops for which it is intended. In ſome parts of France, and in Italy, theſe Vetches are ſown for feeding of cattle while green, and are accounted very profitable; and in many parts of England they are cultivated to feed cart-horſes, &c. though upon ſuch land where Lucern will thrive, it will be much better huſbandry to cultivate that for this purpoſe.

Where theſe plants are cultivated for their ſeeds, they ſhould be cut ſoon after the pods change brown; and when they are dry, they muſt be immediarely ſtacked, for if they are ſuffered to lie out in the field to receive wet, and there comes one hot day after it, the pods will moſt of them burſt, and caſt out the ſeeds. When the ſeeds are threſhed out, the haulm is eſteemed very good food for cattle, and ſome have recommended the ſeeds for horſes, and affirm they are as proper for thoſe animals as Beans; which, if true, will render them more valuable, becauſe theſe will grow on the lighteſt ſandy land where Beans will not thrive, ſo may be a good improvement to ſome counties in England, where they do not attempt to cultivate Beans.

[To inſure a ſucceſſion of Tares during the ſpring and ſummer, ſow upon the wheat ſtubble as ſoon as the wheat is off, or on land well manured, in auguſt; as ſoon as theſe are up, throw in another crop, and in like manner a third. As there will be about a month between the firſt and third ſowing, a regular ſucceſſion will be inſured for the following ſeaſon; eſpecially if another crop be ſown in the ſpring. Some mix a buſhel of black oats with every two buſhel and half of tares: others put in ſome rie with the autumnal ſowings [z].

The quantity ſown an acre, is from two buſhels, or two buſhels and a peck, or two buſhels and a half, to three, or even four buſhels.

On the South downs in Suſſex, they ſubſtitute a double crop of Tares, inſtead of a fallow for wheat. They ſow forward winter Tares, which are fed off late in the ſpring with ewes and lambs: they then plough, and ſow ſummer Tares and Rape, two buſhels and a half of the firſt, and half a gallon of the ſecond; this they feed off with their lambs, in time to plough once for wheat. Thus the land in the fallow year is made to ſupport the utmoſt poſſible quantity of ſheep which its deſtination admits; the two ploughings are given at the beſt ſeaſons, in autumn for the froſt to mellow the lands, and prepare it for a ſucceſſive growth of weeds; and late in ſpring to turn them down: between the

[z] Reports of Suſſex and Kent. Young's Annals, 2. 347.

Digitized by Google

times of giving theſe ſtirrings, the land is covered with crops: the quantity of live ſtock ſupported yields amply in manure: and the treading which the ſoil receives, previous to the ſowing of wheat, gives an adheſion grateful to that plant *.]

Culture of Garden Beans.

22. All the early Beans are generally planted on warm borders under walls, pales, and hedges; and thoſe which are deſigned to come firſt, are uſually planted in a ſingle row pretty cloſe to the fence: and here I cannot help taking notice of a very bad cuſtom, which too generally prevails in gentlemen's kitchen-gardens, which is that of planting Beans cloſe to the garden-walls, on the beſt aſpects, immediately before the fruit-trees, which is certainly a greater prejudice to the trees, than the value of the Beans, or any other early crop; therefore this practice ſhould be everywhere diſcouraged; for it is much better to run ſome low Reed hedges acroſs the quarters of the kitchen-garden, where early Beans and Peas may be planted, in which places they may with more conveniency be covered in ſevere froſt; and to theſe hedges they may both be cloſely faſtened, as they advance in their growth; which, if practiſed againſt the walls where good fruit-trees are planted, will greatly prejudice the trees, by overſhadowing them, and the growth of theſe legumes will draw off the nouriſhment from the roots of the trees, whereby they will be greatly weakened.

But to return to the culture of the Beans. Thoſe which are planted early in october, will come up by the beginning of november; and as ſoon as they are an inch above ground, the earth ſhould be carefully drawn up with a hoe to their ſtems; and this muſt be two or three times repeated, as the Beans advance in height; which will protect their ſtems from the froſt, and encourage their ſtrength. If the winter ſhould prove ſevere, it will be very proper to cover the Beans with Peas-haulm, Fern, or ſome other light covering, which will ſecure them from the injury of froſt; but this covering muſt be conſtantly taken off in mild weather, otherwiſe they will draw up tall and weak, and come to little; and if the ſurface of the border is covered with tanner's bark, it will prevent the froſt penetrating the ground to the roots of both, and be of great ſervice to protect them from the injury which they might otherwiſe receive.

In the ſpring, when the Beans are advanced to be a foot high, they ſhould be faſtened up to the hedge with packthread or a ſmall line, ſo as to draw them as cloſe as poſſible; which will ſecure them from being injured by the morning froſts, which are often ſo ſevere in march and april, as to lay thoſe Beans flat on the ground, which are not thus guarded; at this time all ſuckers which come out from the roots ſhould be very carefully taken off; for theſe will retard the growth of the Beans, and prevent their coming early; and when the bloſſoms begin to open toward the bottom of the ſtalks, the top of the ſtems ſhould be pinched off, which will cauſe thoſe firſt pods to ſtand, and thereby bring them forward. If theſe rules are obſerved, and the ground kept clean from weeds or other plants, there will be little danger of their failing.

But leſt this firſt crop ſhould be deſtroyed by froſt, it will be abſolutely neceſſary to plant more about three weeks after the firſt, and ſo to repeat planting more every three weeks, or a month, till february; but thoſe which are planted toward the end of november, or the beginning of december, may be planted on ſloping banks, at a ſmall diſtance from the hedges; for if the weather is mild, theſe will not appear above ground before Chriſtmas; therefore will not be in ſo much danger as the firſt and ſecond planting, eſpecially if the ſurface of the ground is covered with tan to keep the froſt out of the ground as is before directed; for the firſt planting will, by that time, be a conſiderable height: the ſame directions which are before given will be ſufficient for the management of theſe; but only it muſt be obſerved, that the larger Beans ſhould be planted at a greater diſtance than the ſmall ones; as alſo, that thoſe which are firſt planted muſt be put cloſer together, to allow for ſome miſcarrying; therefore, when a ſingle row is planted, the Beans may be put two inches aſunder, and thoſe of the third and fourth planting may be allowed three inches, and when they are planted in rows acroſs a bank, the rows ſhould be two feet and a half aſunder; but the Windſor Beans ſhould have a foot more ſpace between the rows, and the Beans in the rows ſhould be planted five or ſix inches aſunder. This diſtance may, by ſome perſons, be thought too great; but from many years experience, I can affirm, that the ſame ſpace of ground will produce a greater quantity of Beans when planted at this diſtance, than if double the quantity of ſeeds are put on it. In the management of theſe later crops of Beans, the principal care ſhould be to keep them clear from weeds, and any other plants which would draw away their nouriſhment; to keep earthing them up, and, when they are in bloſſom, to pinch off their tops; which, if ſuffered to grow, will draw the nouriſhment from the lower bloſſoms, which will prevent the pods from ſetting, and ſo only the upper parts of the ſtems will be fruitful; and another thing ſhould be obſerved in planting of the ſucceeding crops, which is, to make choice of moiſt ſtrong land for the later crops; for if they are planted on dry ground, they rarely produce a crop.

Theſe after-crops ſhould be planted at about a fortnight diſtance from each other, from the middle of february to the middle of may; after which time it is generally too late to plant, unleſs the land is very ſtrong and moiſt; for in warm dry light land all the late crops of Beans are generally attacked by the black inſects, which cover all the upper part of their ſtems, and ſoon cauſe them to decay.

Where the ſeeds of theſe Beans are deſigned to be ſaved, a ſufficient number of rows ſhould be ſet apart for that purpoſe, according to the quantity deſired; theſe ſhould be managed in the ſame way as thoſe which are deſigned for the table; but none of the Beans ſhould be gathered, though there are ſome covetous perſons, who will gather all the firſt ripe for the table, and are contented to ſave the after-crop for ſeed, but theſe are never ſo large and fair as the firſt; ſo that if theſe are for ſale, they will not bring near the price as the other; therefore, what is gained to the table is loſt in the value of the ſeed; but thoſe who are deſirous to preſerve the ſeveral varieties as pure as poſſible, ſhould never ſuffer two of the varieties to grow for ſeeds in the ſame place; for by their farina mixing with each other they will not continue ſo pure, but be apt to vary; and in order to keep the early kinds perfect, thoſe which come the earlieſt ſhould be ſaved for ſeeds; but this is what few people chuſe to do, becauſe they are then the moſt valuable.

When the ſeed is ripe, the ſtalks ſhould be pulled up, and ſet upright againſt a hedge to dry, obſerving to turn them every third day, that they may dry equally; then they may be threſhed out, and cleaned for uſe, or otherwiſe ſtacked up in a barn, till there is more leiſure for threſhing them out; and afterward the ſeed ſhould be drawn over to take out all thoſe that are not fair, preſerving the beſt for uſe or ſale.

It is a very good method to change the ſeeds of all ſorts of Beans, and not to ſow and ſave the ſeeds long in the ſame ground, for they do not ſucceed ſo well; therefore, if the land is ſtrong where they are to be planted, it will be the beſt way to procure the ſeeds from a lighter ground, and ſo vice verſa; and by this method the crops will be larger, and the Beans fairer, and not ſo liable to degenerate.

Culture of Field Beans.

Having given directions for the culture of the Garden Beans, I ſhall next proceed to that of the Horſe Bean, which is cultivated in the fields: there are two or three varieties of theſe, which differ in their ſize and colour; but that which is now in the greateſt eſteem, called the Tick Bean; this does not grow ſo high as

* Young's Annals, 17. 141. ſee 6. 215. and 8. 110. and 9. 507. and 12. 303.

Digitized by Google

the other, is a more plentiful bearer, and ſucceeds better on light land than the common Horſe Bean.

The Horſe Bean delights in a ſtrong moiſt ſoil, and an open expoſure, for they never thrive well on dry warm land, or in ſmall incloſures, where they are very ſubject to blight, and are frequently attacked by a black inſect, which the farmers call the black dolphin; theſe inſects are often in ſuch quantities as to cover the ſtems of the Beans entirely, eſpecially all the upper part of them; and whenever this happens, the Beans ſeldom come to good: but in the open fields, where the ſoil is ſtrong, this rarely happens.

Theſe Beans are uſually ſown on land which is freſh broken up, becauſe they are of uſe to break and pulverize the ground, as alſo to deſtroy weeds; ſo that the land is rendered much better for corn, after a crop of Beans, than it would have been before, eſpecially if they are ſown and managed according to the new huſbandry, with a drill plough, and the horſe hoe, uſed to ſtir the ground between the rows of Beans which will prevent the growth of weeds, and pulverize the ground, whereby a much greater crop may, with more certainty, be expected, and the land will be better prepared for whatever crop it is deſigned for after.

The ſeaſon for ſowing theſe Beans is from the middle of february to the end of march, according to the nature of the ſoil; the ſtrongeſt and wet land ſhould always be laſt ſown; the uſual quantity of Beans ſown on an acre of land is about three buſhels; but this is double the quantity which need be ſown, eſpecially according to the new huſbandry; but I ſhall firſt ſet down the practice according to the old huſbandry, and then give directions for their management according to the new. The method of ſowing is after the plough, in the bottom of the furrows; but then the furrows ſhould not be more than five, or at moſt ſix inches deep. If the land is new broken up, it is uſual to plough it early in autumn, and let it lie in ridges till after Chriſtmas; then plough it in ſmall furrows, and lay the ground ſmooth; theſe two ploughings will break the ground fine enough for Beans, and the third ploughing is to ſow the Beans, when the furrows ſhould be made ſhallow, as was before mentioned.

Moſt people ſet their Beans two cloſe; for, as ſome lay the Beans in the furrows after the plough, and others lay them before the plough, and plough them in; ſo, by both methods, the Beans are ſet as cloſe as the furrows are made, which is much too near; for when they are on ſtrong good land, they generally are drawn up to a very great height, and are not ſo apt to pod as when they have more room, and are of lower growth; therefore I am convinced by many late trials, that the better way is to make the furrows two feet and a half aſunder, or more; which will cauſe them to branch out into many ſtalks, and bear in greater plenty than when they are cloſer; by this method, half the quantity of Beans will be ſufficient for an acre of land; and by the ſun and air being admitted between the rows, the Beans will ripen much earlier and more equally than in the common way.

What has been mentioned muſt be underſtood as relating to the old huſbandry; but where Beans are planted according to the new, the ground ſhould be four times ploughed before the Beans are ſet, which will break the clods, and render it much better for planting; then with a drill plough, to which a hopper is fixed for ſetting the Beans, the drills ſhould be made at three feet aſunder, and the ſpring of the hopper ſet ſo as to ſcatter the Beans at three inches diſtance in the drills. By this method leſs than one buſhel of ſeed will plant an acre of land. When the Beans are up, if the ground is ſtirred between the rows with a horſe plough, it will deſtroy all the young weeds; and when the Beans are advanced about three or four inches high, the ground ſhould be again ploughed between the rows, and the earth laid up to the Beans; and if a third ploughing, at about five or ſix weeks after, is given, the ground will be kept clean from weeds, and the Beans will ſtalk out, and produce a much greater crop than in the common way.

When the Beans are ripe, they are reaped with a hook, as is uſually practiſed for Peas; and after having lain a few days on the ground they are turned, and this muſt be repeated ſeveral times, until they are dry enough to ſtack, but the beſt method is to tie them in ſmall bundles, and ſet them upright; for then they will not be in ſo much danger to ſuffer by wet, as when they lie on the ground; and they will be more handy to carry and ſtack, than if they are looſe. The common produce is from twenty to twenty-five buſhels on an acre of land; but I have known thirty-ſix on an acre.

The Beans ſhould lie in the mow to ſweat, before they are threſhed out; for as the haulm is very large and ſucculent, ſo it is very apt to give and grow moiſt; but there is no danger of the Beans receiving damage, if they are ſtacked tolerably dry, becauſe the pods will preſerve the Beans from injury; and they will be much eaſier to threſh after they have ſweated in the mow than before; and after they have once ſweated and are dry again, they never after give.

By the new huſbandry, the produce has exceeded the old by more than ten buſhels on an acre; and if the Beans which are cultivated in the common method are obſerved, it will be found that more than half their ſtems have no Beans on them; for by ſtanding cloſe, they are drawn up very tall; ſo the tops of the ſtalks only produce, and all the lower part is naked; whereas in the new method, they bear almoſt to the ground; and as the joints of the ſtems are ſhorter, ſo the Beans grow cloſer together on the ſtalks.

In the year 1745 I made the following experiment, in planting a piece of eleven acres of Beans in Berkſhire; the gentleman's bailiff, who was wedded to the old practice of huſbandry, was very unwilling to depart from it; and having been an old ſervant in the family, his maſter was inclinable to hear all he could ſay in favour of his opinion: however, at laſt I prevailed on the gentleman to let his bailiff plant one half of the land in his way, giving him the choice which half he would have: accordingly the land was divided and planted; but the ſummer proving wet, the Beans on that part of the field he had choſen grew ſo tall and rank, that they produced no pods but on the upper part of the ſtalks; and when they were threſhed out, there was no more than twenty-two buſhels on an acre, whereas the other half produced near forty.

[Whatever the preceding crop, whether corn, or old graſs, plough but once for planting Beans, which ſhould be performed as ſoon as the Chriſtmas froſts break up. Provide poles of ſlit deal planed ten feet long, an inch thick, and two inches broad, bore holes through them at ſixteen inches aſunder, paſs packthreads through theſe holes to the length of the lands you are about to plant, and there ſhould be a pole at every fifty yards; four ſtakes at the corner of the extreme poles, faſten them to the ground, the intention is to keep the lines every where at equal diſtances and ſtraight, to facilitate horſe-hoeing. Then women take beans in their aprons, and with a dibber pointed with iron, make holes along the ſtrings with their right hand, and put the bean in with their left; while they are doing one ſet of lines, another ſhould be prepared for them. Near London they are paid three ſhillings and three ſhillings and ſix-pence a buſhel for planting; but where they are not accuſtomed to it, they do it by the day.

By the time the cold eaſterly winds come in the ſpring, they will be high enough to hand hoe, if they were early planted, and it is of conſequence on ſtrong ſoils to catch every dry ſeaſon for ſuch operations. The hoes ſhould be eight inches wide, the whole ſurface between the rows carefully cut, and every weed eradicated. This hoeing coſts near London, from five ſhillings to ſeven ſhillings and ſixpence an acre. When the beans are about ſix inches high, they ſhould be horſe-hoed with a ſhim, the cutting part ten or eleven inches wide. This tool is cheap, ſimple, and not apt to be out of order; one horſe draws it, which ſhould be led by a careful perſon, another holding the ſhim, and guiding it carefully in the centre between the rows. It cuts up all weeds effectually,

Digitized by Google

fectually, and loofens the earth two or three inches deep; in a little time after this operation the hand hoe ſhould be ſent in again to cut up what the ſhim may have paſſed, and to extract the weeds that grow too near the Beans, for that tool to take them. If the weather is dry enough, a ſecond horſe-hoeing with the ſhim ſhould follow when the Beans are nine or ten inches high, but if the weather is wet, it muſt be omitted, the hand-hoe however muſt be kept at work enough to keep the Beans perfectly free from weeds [b].

Common Ticks is the Bean generally cultivated in Kent, in which county the culture of this pulſe is ſuppoſed to be beſt underſtood. It is uſed there for fattening hogs, and as food for horſes. The Beans are uſually drilled, dropped by hand, or boxed, in furrows eighteen inches apart, from three and a half to four buſhels to the acre, in february and march. They are generally hand and horſe-hoed twice, and ſometimes three times, and laſtly hand-weeded. The crop is reaped at the end of auguſt or beginning of ſeptember. The produce is from two to ſix quarters on an acre, according to the ſtrength of the land and the management.

May Beans are a larger ſort of Ticks, and ſomewhat earlier ripe. They are ſometimes very productive, but being larger are not ſo heavy, and therefore of rather leſs value per quarter. Four buſhels, and ſometimes four and a half of this kind are dropped in by hand on an acre.

The Eſſex Ticks are much ſmaller than the Common Tick, and of a rounder ſhape. They ripen ſix or eight days later than that, and are not ſo productive, but more valuable, being heavier.

The French Ticks are ſtill ſmaller, being only as big as a moderate-ſized Pea, and nearly circular: this ripens the lateſt of any ſort, but is moſt valuable when dry, on account of its great weight. They will grow on ſome ſorts of poor land, but they are not very productive. Three buſhels of theſe ſmall ſorts are ſufficient to ſeed an acre when drilled; which is the beſt method by far of putting them in.

The Toker is the largeſt Garden Bean, and ſomewhat of an oval ſhape. Many are found an inch and half in length. The Beans are dropped by hand in rows about twenty inches apart, as ſoon as the land is ſufficiently dry in the ſpring. The quantity of ſeed about five and a half or ſix buſhels to the acre. This crop is kept perfectly free from weeds during the ſummer, and is pulled up by hand in harveſt: it is ſet up in lumps of a ſheaf at a place to dry, in a conical form, the butt-end being ſpread out as wide as poſſible, to prevent their being blown down. They are threſhed by the flail, and cleaned with the caſting-ſhovel and ſpry, like the other ſorts; and then culled by women, to take out every rotten and ſtained Bean, before they are ſent to market. The produce is from three to ten quarters on an acre.

The Windſor Bean is ſomewhat leſs, not ſo long, and more approaching to a ſquare form. It is managed in every reſpect as the Toker, only requiring a little leſs ſeed. Its produce is generally ſomewhat leſs, and its value a little more.

The Long-pod is about half the ſize of the Toker: it is an earlier ſort, and much uſed by the London gardeners. Four buſhels and a half to the acre is dropped by hand in rows eighteen inches apart. It is managed as the other garden Beans, and the produce is from three to ſix quarters.

The Spaniſh or Liſbon is a ſtill ſmaller kind, and ripens about the ſame time. The Mazagan is the ſmalleſt and earlieſt ripe.

The Spaniſh is dropped in by hand, about four buſhels and a half to the acre, in rows eighteen inches apart. The Mazagan is frequently drilled four buſhels to the acre. Theſe two ſorts are reaped as common Beans: the produce of the firſt is from three to five quarters, and ſometimes much more:—of the ſecond, from two quarters and a half to four and a half [c].

Mr. Marſhall, in his Rural Economy of Gloceſterſhire, has detailed the cultivation of pulſe in the vale of Gloceſter.

[b] Young's Iriſh tour, vol. 2.

[c] Boys, ſurvey of Kent, p. 85. 8vo ed.

It invariably ſucceeds a corn crop: namely, wheat in the old fallow field courſe; barley in the new; and either wheat or barley on the every year's lands.

They begin ploughing as ſoon after Chriſtmas as the ſeaſon will permit, fetching up the ſoil as deep as the plough will turn it; nine, ten or more inches deep; and let it lie in whole furrow to take the froſt.

They begin about Candlemas, or as ſoon after as the land can be got upon with the harrows, to break the plits and level the ſurface for the ſetters. The ſoils of this vale moſtly fall like lime after being frozen; ſo that once going over with the harrows is ſufficient to reduce the ſurface to powder as fine as aſhes, leaving not the trace of a whole furrow.

Setting is done by women. The method varies in different parts of the diſtrict. In the central and ſouthern quarters, they ſet acroſs the ridges by the eye, without a line. About Cheltenham and along the northern border, they ſet along the ridges by a line. About Tewkſbury, and towards Deerhurſt, it is common to ſet by a line, acroſs the ridges.

In theory, a line appears to be neceſſary. Women however, who have been long in the habit of ſetting without one, ſet pretty regularly by the eye; and the young ones are trained up, by putting one of them between two who are experienced.

Each ſetter has a ſetting pin, and a ſatchel, (provincially tuckin.) The ſetting-pin reſembles the gardener's dibble: but it has a croſs-pin or half crutch near the top, to reſt the palm upon; and a groove on each ſide of the main pin to receive the forefinger and thumb: the length of the dibble is about eight inches; of the handle about four.

In ſetting the women walk ſideway, to the right, with their faces toward the ground which is ſet: the laſt row therefore is immediately under the eye, and the difficulty of ſetting another row, nearly parallel with it, is readily overcome by practice.

The diſtance between the rows varies from ten to fourteen inches: twelve may be conſidered as the prevailing width. The diſtance in the rows about two inches. The holes about two inches deep: and one Bean dropped in each hole.

The quantity of ſeed from two buſhels and a half to three buſhels on an acre.

The price of ſetting, ſixteen to eighteen pence a buſhel: coſting from three ſhillings and ſixpence to four ſhillings and ſixpence an acre.

Covering generally done with tined harrows, drawn once in a place: but if the ſoil be ſo light that the tines pull up the Beans, a thorn-harrow is made uſe of.

Preſently after the Beans are above ground, the ſurface is ſometimes looſened with the harrow, previous to the hoeing. The method of doing which is the common one practiſed by gardeners in drilled crops. The width of the hoe is five inches.

The ſecond hoeing ſhould be deferred as long as it can be with ſafety; but it ought always to be finiſhed before the Beans begin to bloſſom. In this hoeing, the rows muſt be carefully hand-weeded. Both of them are flat, without earthing up the Beans. The price of both, including hand-pulling, is ſix ſhillings an acre: more or leſs, according to the crop, and its degree of foulneſs.

A ſhort, low-podded crop is mown, uſually with a naked ſcythe: but tall Beans are uſually cut with a reaping-hook, and a hooked ſtick. In the former caſe they are gathered into rows with forks, and then into wads or bundles:—in the latter, they are either bound in ſheaves, and ſet up in ſhocks; or more uſually in hackles, or one enormous conical ſheaf.

They are uſed for feeding horſes and fatting hogs; and are bought up in great quantities at Briſtol for the inns, and for Guinea ſhips, as food for the negroes, in their paſſage from Africa to the Weſt Indies.

The produce is about three quarters an acre: four quarters, (or thirty-eight Wincheſter buſhels,) are not a very extraordinary crop; though much of the land has borne Beans every third year, and ſome of it perhaps every ſecond year, during a ſucceſſion of ages [d].

[d] Vol. 1. p. 140 to 154.

Beans

Beans are excellent on ſtrong clays, and wet loams as a preparation for wheat, inſtead of a fallow. The thick ſhade from this crop cauſes a putrid fermentation in the height of ſummer, opens the land, and looſens the ſoil. On this theory, Mr. Fiſke, in march 1767, mucked ſix acres of barley ſtubble, and ſet it with Windſor Beans. The produce was twenty-four quarters, twenty-three of which were ſold to a gardener at Bury for thirty-ſix ſhillings the quarter.

October following, the ſame field was ſown with wheat: the produce upwards of three quarters on the acre; which was more by half a quarter than any that year from a clean fallow.

March 1768, ſixteen acres were ſet with the common Horſe Bean, upon an oat-ſtubble, ploughed at michaelmas, and mucked before the ſetting: the produce four quarters and a half to the acre. Wheat ſucceeded, which was the beſt in the pariſh.

In 1782, to prove the uſe of the bean culture as a preparation for barley, four acres in an eight acre field were ſown with turneps; two were ſet with Tick Beans; and two acres were a clean fallow. The Beans were kept clean: the turneps were hoed, and fed off with ſheep. The ſpring following, the whole field was ſown with barley: that after Beans was the beſt; after the fallow next; after turneps by much the worſt.

In the culture of Beans, they muſt be kept clean, which cannot be done but by hoeing early; and they muſt be manured for plentifully, twenty-five three-horſe loads of compoſt earth and dung to the acre; in order that a large crop may be obtained, which is not only of great importance in itſelf, but alſo to that which is to ſucceed; for every buſhel gained in the crop of Beans, is a certain gain in the wheat or barley which follows [c].

Stem herbaceous erect, leaves lanceolate acute.

DESCRIPTIONS, *&c.*

1. Root perennial, creeping with branched fibres. The whole plant ſmooth and ſhining. Stems round, ſlender, leafy, erect when in flower, from nine inches to a foot in height, and much higher when ſupported by buſhes, marked on each ſide with a groove faintly impreſſed; after flowering, proſtrate, elongated, taking root at their joints. Mr. Woodward remarks, that the flowering-ſtem is upright in the ſpring, but that in autumn the flowers are borne on the ſhoots of the year, which are trailing. Leaves oppoſite, on footſtalks about one fourth the length of the leaves, which are quite entire, evergreen, ſhining, ſomewhat like thoſe of Privet, not having the fringed edge obſervable in V. major. Flowers axillary, alternate, ſolitary, void of ſcent, on nearly upright peduncles, almoſt twice the length of the leaves, round, ſmooth and ſhining. Calyx bell-ſhaped, five-cleft, ſmooth, with ſhort lanceolate ſegments; much ſhorter and leſs tapering than in V. major. Corolla blue with a white eye, varying to purple and white; of a darker colour and ſmaller ſize than in V. major [f].

This plant, like many others which run much at the root, ſeldom produces its follicles. Mr. Curtis and Dr. Smith inform us, that they have never ſeen them. Tournefort ſays that he never ſaw any fruit in Provence or Languedoc, where this plant is very common, nor about Liſbon; that Cæſalpinus is the only author who has deſcribed it, and that he obtained that which is engraved in his Elements by ſetting the plant in a pot with little earth. Miller did not ſucceed that way, but by cutting off all the lateral ſhoots. Leers affirms that the follicles are always two-ſeeded.

Whoever, ſays Mr. Curtis, looks into the tube of this flower with any degree of attention, muſt be ſtruck with the wiſdom ſhewn in the formation of the parts contained within it. Each anther is terminated by a membrane which bends over at top, and the membranes of all the anthers cloſing together, effectually ſeclude every thing that might injure the parts of the fructification below them. The filaments ſomewhat reſemble in ſhape a note of interrogation; the anthers in ſtructure are very ſimilar to thoſe of the violet, and open inwardly in the ſame manner; the ſtyle, which in moſt flowers is broadeſt at top, is here the ſlendereſt; they are two in number, but ſo cloſely united, that without a magnifier, the diviſion is ſcarcely to be perceived; the ſtigmas, according to Linneus, are two, it is moſt probable however, that the loweſt, which is flat with a glutinous edge, and forms a kind of ring round the ſtyle, is the true ſtigma; the top is a little elevated above this, and appears like a round white ball, which when magnified, is found to conſiſt of a number of hairs diverging from one centre, and is a very pleaſing ſight in the microſcope.

The ſmall Periwinkle varies much in the colour of the flowers, pale blue, purple, and white; they are alſo double; and the foliage is ſometimes variegated, either with white or yellow ſtripes.

At the foot of a ſheltered hedge expoſed to the morning ſun, it flouriſhes very much, eſpecially if the ſoil be moiſt; the flowers are there very ornamental in ſpring, and continue a month or ſix weeks [h]. They appear earlier than thoſe of V. major.

Native of Germany, Switzerland, France, Italy, Britain, &c.

Mr. Curtis ſays he has noticed it only in one ſpot near London; in the hedge of a field on the left hand ſide of Lordſhip lane near Dulwich, where it had every appearance of being wild. Merret however found it on the weſt of Hampſtead heath, and Dr. Milne in many other places, as in Bellſize lane, on the left hand in going from Primroſe hill to Hampſtead, in great abundance; under the paling of Clandon Place park; in a lane betwixt Hayes church in Kent and the common; at Addington; below Singlewell church near Graveſend, plentifully; a mile beyond Bexley on the Dartford Road; by the ſide of the paling of Miſtley park; between Milton near Swanſcomb and Knockhall; at the bottom of a lane leading from Eltham to Southend, in the Foot's Cray road; about a mile from Sydenham; about two miles and a half from Croydon, in the way to Coombe; at Cobham in Surry; between Walthamſtow and Low Layton; and on a cliff near Stone church, among the buſhes. Blackſtone perceived it in a lane leading from Uxbridge moor to Iver heath, and in a little grove near Breakſpears, Middleſex. Mr. Warner found it on the left hand of the footway from Woodford to the church, and on the iſlands in his own gravel-pit pond. In the Feverſham catalogue it is mentioned as growing in Hay's wood, near Southſtreet, Bocton. Near Lewes in Suſſex. By Honingham church, Norfolk, plentifully, and in ſeveral lanes in that pariſh, undoubtedly wild, according to Dr. Smith. In Earſham wood, by Mr. Woodward. In Cambridgeſhire, under a hedge by Maid's Cauſeway, near the town at Cherry Hinton, near the church, and at Triplow-Potton and Aſpley in Bedfordſhire, by Dr. Abbot. In Magdalen College walks, between Wolvercot and Yarnton, and Cornbury, Oxfordſhire, by Dr. Sibthorp. Rainſal brow near Mancheſter, by Mr. Caley. Near Rippon in Yorkſhire, by the Rev. Mr. Dalton and Mr. W. Brunton, perfectly wild. In Coryton woods, Scotland, by Dr. Parſons.

It was found with a white flower, at Chilrington, four miles from Lewes, by Mr. Woolgar, of the latter place: and with a ſtriped leaf, in the field-way from Hampſtead to Willſdon; at Weſt Wickham in Kent; in a wood near Erith; about half a mile from Tottenham; at Clandon place; and at Cobham, by Dr. Milne and Mr. Alex. Gordon [i].

2. This is larger in all its parts than the preceding. Stems erect, finally rooting at the end. Leaves broad-ovate three inches long and two broad, of a thick conſiſtence, finely fringed with ſhort rigid hairs at the edge, on thick footſtalks. Flowers ſolitary, alternate, on peduncles half the length of the leaves. Calyx-teeth elongated, briſtle-ſhaped, often ciliate, ſpreading at the tip. Corolla fine purpliſh blue, twiſted. Follicles very ſmooth and ſhining, awl-ſhaped at the top, divaricating. Seeds moſtly two, one above the other, oblong, with a longitudinal groove at top, roughiſh, but naked [k]. Calyx as long as the tube of the corolla; which is woolly within juſt above the anthers. Corolla blue with a bluſh of purple. Petioles long [l].

Flowering-ſtems two feet high and upwards, round but the ſides alternately ſomewhat flattened, ſmooth, dotted with red; other ſtems, producing no flowers, creep on the ground or climb up neighbouring plants. Peduncles longer than the leaves. Flowers large, pale blue with a whitiſh mouth [m]; varying to white. The foliage alſo is ſometimes ſtriped.

Linneus, (in ſyſt. veg.) aſſerts this to be a variety of the minor. And Monſ. Gerard (in Flora Gallo-Provinc.) ſays, that nature has not put any limits between them. They ſeem however to be as diſtinct as many other ſpecies of natural genera. Haller's remark of the fringe at the edge of the leaves in this, would be ſufficient to diſtinguiſh them, if there were nothing elſe; but ſeveral other marks are ſpecified above.

Native of France, Spain, Italy, Switzerland, England, and Algiers. With us it is more common in a wild ſtate than the preceding, in moiſt woods, and hedges. Mr. Curtis noticed it near London, under Lord Stormont's park pales, between Wandſworth and Putney common, and in a field near Beckenham in Kent, where it was certainly wild. Dr. Milne found it moſt abundantly between that village and Croydon, and near Beckenham church, and in innumerable other places in Kent, Surry, Eſſex, and Middleſex. It was obſerved by How, who publiſhed his Phytologia in 1650, near Kingſland, whence it is now doubtleſs ex-

tirpated. This was probably the firſt notice of its being found wild in England; ſince Gerarde and Parkinſon give no hint of its being ſo. Even Ray, in his hiſtory (1688) does not mark it as an Engliſh plant. Plot (1677) found it between Wolvercot and Yarnton, in Oxfordſhire, where Sibthorp marks the minor. Near Colcheſter, by Dr. Richardſon. In the way from Knowlton to Deal, and in a lane before you come to Foot's Cray from Rochill, by Mr. James Sherard [n]. In a meadow near Harefield church, by Blackſtone. Near Walthamſtow, by Warner. Southorp in Northamptonſhire, by Morton. Obſerved by Profeſſor John Martyn, before 1732, at Madingley in the way to Drayton, on the outſide of St. John's College, and in many other places in Cambridgeſhire. At Coton in the ſame county, near the church in 1759, at Girton, Whittlesford, Rampton, and Bottiſham, by Mr. Relhan. At Ravenſden and Clapham in Bedfordſhire, by Dr. Abbot. In a grove at Thorpe, near Norwich, by Mr. Woodward. In Magdalen College walks, Oxford, by Dr. John Sibthorp. In the Iſle of Wight, to the ſouth of Yarmouth, plentifully, by Dr. Withering.

It having been doubted whether theſe plants are really wild in England, I have given the above numerous places of growth. They probably eſcaped originally out of gardens, and increaſing ſo readily have gradually diffuſed themſelves. However that may be, having been noticed in a wild ſtate, during a century and half, they may now fairly be reputed indigenous. It flowers in may.]

As theſe plants delight to grow under the cover of trees and buſhes, they may be made ornamental in large gardens, if they are planted on the verges of wilderneſſes, where they will ſpread and cover the ground: and as their leaves continue green all the year, they will have a good effect in winter, and their flowers appearing great part of ſummer, will add to the variety.

[3. This has the appearance of an Echites. Native of Carolina.]

4. Stem upright, branching, three or four feet high, when young, ſucculent, jointed, purple; but as the plant advances the lower parts become woody. The branches have the joints very cloſe, are covered with a ſmooth purple bark, and have oblong, ovate, entire leaves, two inches and a half long, and an inch and half broad, ſmooth and ſucculent, ſetting pretty cloſe to the branches. Flowers axillary, ſolitary, on very ſhort peduncles: tube long and ſlender; brim ſpreading open flat, divided into five broad obtuſe ſegments, which are reflexed at their points. The upper ſurface of the petal is of a bright crimſon or peach colour, and their under ſide pale fleſh-colour. There is a ſucceſſion of flowers, from february to the end of october. Thoſe which appear early in the ſummer are ſucceeded by taper ſeed-veſſels, filled with roundiſh black ſeeds, which ripen in autumn.

[Stem ſomewhat rigid, round, ſmooth and even. Leaves oppoſite, lanceolate-oval, coriaceous with a white midrib: the petioles have a toothlet on each ſide at the baſe. Flowers axillary, ſeſſile in pairs. The calyx ends in five awl-ſhaped briſtles. Corolla ſalver-ſhaped; ſegments half-ſickle-ſhaped, obtuſe, mucronate, roſe-coloured with a dark-purple eye [o] and a white circle within it.

Mr. Curtis remarks, that the flowers do not always grow in pairs. It varies with a white flower, having the eye only purple.

Follicles two, ſmall, round, ſubclavate, ſtriated, pubeſcent, half-two-celled, opening by the inner ſide: partition narrow, doubled, taking its riſe from the future plaited inwards. Seeds from ſixteen to twenty in each follicle, ſmall, ovate, acuminate above, on one ſide grooved and rugged with ſharp tubercles, on the other ſide ſmooth in the middle and having a ſmall umbilical teat, of a cheſnut-brown or blackiſh colour, and bald: they are faſtened longitudinally on each ſide of the partition [p].]

The ſeeds of this beautiful plant came originally from the iſland of Madagaſcar to the royal garden at Paris, and were communicated by Monſ. Richard to Mr. Miller, who cultivated them in 1757. [It has ſince been found in Java, China, Cochinchina and Japan.

5. The other ſpecies are perennial, this is annual. Stem a ſpan high, quadrangular. Flowers at the ſides, and often at the top, in pairs, peduncled. Corolla of the ſame ſize and colour with that of Lithoſpermum officinale [q].

Stem branched, even. Leaves ſinuate-toothed, ſomewhat rugged. Flowers uſually in pairs, on ſhort pedicels, axillary, in a briſtly involucre, ſmall with a long tube. Follicles linear, ſtriated, as it were jointed [r].

Native of the Eaſt Indies. Sent from Tranquebar by the indefatigable Konig. It is there a troubleſome weed in the gardens.—Introduced in 1778 by Sir Joſeph Banks. It flowers here in auguſt [s].]

PROPAGATION AND CULTURE.

1, 2. Theſe are eaſily propagated by their trailing ſtalks, which put out roots very freely: and if the ſtalks of the large ſort are laid in the ground, they will root very ſoon, and may be cut off and tranſplanted where they are to remain, and when they are once rooted, they will ſpread and multiply very faſt without farther care.

4. Sow the ſeeds upon a moderate hot-bed in the ſpring, and when the plants are fit to remove, tranſplant them on to a freſh hot-bed, at about four inches diſtance, ſhading them till they have taken new root: then treat them in the ſame way as other natives of warm countries; taking great care to prevent their drawing up weak, and not giving them too much water. When the plants have obtained ſtrength, take them up carefully with balls of earth to their roots, plant them in pots filled with good earth, and plunge them into a moderate hot-bed to facilitate their taking new root, obſerving to ſcreen them from the ſun, and when they are well rooted to enure them gradually to bear the open air: but unleſs the ſummer prove warm, theſe plants ſhould not be placed in the open air, for they will not thrive if they are expoſed to cold or wet; therefore during the ſummer they ſhould be placed in an airy glaſs-caſe, and in winter they muſt be removed into the ſtove, where the air is kept to a temperate heat.

It may alſo be increaſed by cuttings planted in pots during any of the ſummer months. Plunge the pots into a moderate hot-bed, and if they are cloſely covered with bell or hand-glaſſes, they will put out roots the more readily: when they have ſo done, they muſt be gradually hardened, and afterwards planted in pots and treated in the ſame way as the ſeedling plants.

Stem creeping herbaceous, leaves oblong, peduncles one-flowered.

DESCRIPTIONS, *&c.*

1. Root perennial. Leaves five-parted, the ſegments ovate, the middle ſegment wider, the outer one toothed only at the baſe [t].

Native of Virginia. It flowers here in may and june; and was cultivated by Mr. Miller in 1739 [u], as appears from his ſupplementary volume, publiſhed that year, and in which he has given thirty violets, many of which he omitted in the later editions of his Dictionary.

It is a ſingular ſpecies, and rare in this country, having no ſweet ſcent to recommend it [x].]

2. The leaves are divided into ſeven parts or lobes, [which are ſometimes toothed: they are of the ſort called pedate by Linneus.] The flowers ſtand upon naked foot-ſtalks: they are blue and have no ſcent either in this or the preceding ſpecies.

They appear in june, but are not ſucceeded by ſeeds here. Native of North America. [Cultivated in 1759, by Mr. Miller.]

3. This is a very low plant, ſeldom riſing two inches high. The leaves are ſmall and pinnatifid. The flowers are pale blue, and appear in june.

[It is like the preceding, but differs in having the ſegments more numerous, not produced at the baſe, lobed, and the outer ones only ſomewhat toothed [y].

This ſingular ſpecies, ſays Monſ. Villars, has the leaves rather digitate than pinnate; the ſegments, four or five in number, are obtuſe. The flower is ſmall, and on a ſcape three or four inches in length.

Root ſlender, branched. Root-leaves numerous, ſmooth, thickiſh, compoſed of three pairs of lobes, and an end one: the firſt four or five-cleft, with unequal blunt ſegments, the middle one obtuſely and ſhortly bifid and trifid. Flowering ſcape from the root, with two capillary briſtles, ciliate at the baſe. Flower nodding: ſegments of the calyx ovate, large, white, the uppermoſt very ſmall: the two uppermoſt petals ſmooth; the two middle very large, bearded, marked with lines, pale; the loweſt ſmooth, more ſlender, with blue lines. Allione remarks, that he has often ſeen two or three petals only. Fruit large, ovate, with ſpherical orange-coloured ſeeds [z].

Native of the mountains of ſouthern Europe and Siberia. Sent to Mr. Miller by Allione, and cultivated by him in 1759.

4. Leaves unequally and remotely ſerrate, below the middle gaſh-ſerrate, veined, ſubpubeſcent, a finger's length: petioles longer than the leaves, ſemicylindric, ſomewhat hairy. Scapes filiform, long, one-flowered, four-cornered, having a few hairs ſcattered over them, and a ſmall lanceolate leaf or two, reflexed at the top. Calyx-leaves lanceolate, acute, ſmooth. Petals oblong-ovate, blue: the uppermoſt white below the middle with blue veins, hairy within at the baſe, little more than an inch and half in length; the lateral ones a little longer than the uppermoſt, hairy and whitiſh at the baſe; the loweſt of the ſame length with theſe, whitiſh at the baſe, and beardleſs.

Native of Penſylvania. Introduced in 1775, by John Fothergill, M.D. It flowers in july, and is perennial [a].

5. The Canadian plant introduced by Kalm, has narrow leaves, on long petioles, with alternate parallel nerves, indiſtinctly ſerrate. Gmelin's Siberian plant has ovate-lanceolate leaves, on petioles ſhorter by half than the leaf, leſs ſtriated, and the flowers larger [b].

Mr. Forſter informs us that they are different ſpecies: Kalm's plant from Canada having very narrow lanceolate ſhining leaves, and a fibrous root throwing

V I O

out runners. Gmelin's from Siberia having ovate-lanceolate pubeſcent leaves, with a fuſiform root, and ſtemleſs.

The former was introduced here in 1785, by Mr. Archibald Menzies [c].

6. Leaves crenate-ſerrate, an inch and half long. Petioles twice or thrice as long as the leaves, ſemicylindric, channelled, ſmooth. Scapes filiform, ſemicylindric, ſmooth, erect, for the moſt part of the ſame length with the petioles. Calyx-leaves ſmooth. Petals oblong-ovate, ſtraw-coloured, blue at the baſe: the uppermoſt half an inch long, ſtreaked with blue, beardleſs; the lateral ones a little narrower and longer, bearded below the middle; the loweſt of the ſame length with the lateral ones, but a little wider, beardleſs. Native of Penſylvania and Virginia. Cultivated in 1762, by Mr. James Gordon. It flowers in may and june.

7. Leaves ſerrate, attenuated at the end, two inches and more in length. Petioles twice as long as the leaves, flat above, ſmooth. Scapes filiform, ſubcylindric, having a very ſmall leaf or two in the middle, for the moſt part the length of the petioles, reflexed at the end. Calyx-leaves ſmooth. Petals ovate-oblong, blue: the uppermoſt half an inch long, whitiſh below the middle, with violet-coloured veins, beardleſs; the lateral ones longer, whitiſh below the middle, bearded; the loweſt whitiſh at the baſe, beardleſs. Native of North America. Introduced in 1772, by Samuel Martin, M.D. It flowers in july [d].

8. Leaves very blunt, crenate, decurrent along the petiole, exactly as in Primula officinalis [e]. Native of North America. Said alſo to be found in Siberia, and in China near Canton.—Introduced in 1783, by Mr. William Young. It flowers in june [f].

9. Root ſomewhat woody, fibrous. Stem none. Runners or ſcions ſhort, ſimple, proſtrate but not taking root. Leaves nearly upright, heart-ſhaped, ſerrate, veiny, clothed on both ſides with ſhort denſe hoary hairs, on long hairy footſtalks, the hairs ſhort ſpreading and bent down. Stipules in pairs, radical, lanceolate, toothed. Scapes taller than the leaves, ſmooth, erect, one-flowered, bearing below their middle a pair of lanceolate ſmooth bractes. Flower nodding, blue, ſcentleſs. Calyx ſmooth. Lateral petals marked with a hairy line, as in V. odorata. Filaments flat. Anthers terminating in an orange-coloured membrane, cloſe but not united. Capſule roundiſh, hairy, containing ſeveral round ſeeds [g].

Mr. Curtis diſtinguiſhes this ſpecies from the odorata. It throws out young ſtalks, but then they are not procumbent, nor do they ever ſtrike root as thoſe of the odorata do; hence the hirta does not increaſe ſo faſt, nor ſpread ſo wide. Linneus makes a conſiderable difference in the form of the roots, but this proceeds chiefly from their age; for in both ſpecies, the older they are, the more tubercles or cicatrices are formed by the annual ſhedding of the leaves. The petioles form the moſt obvious difference: in the odorata they are nearly ſmooth, in this they are very hirſute, and this hairineſs puts on a ſilvery appearance in the young plants. The leaves in both are ſomewhat hirſute underneath; but thoſe of the hirta, in particular ſoils or ſituations, are ſometimes remarkably ſo; and thoſe of the odorata have a more gloſſy appearance on their upper ſurface: in the hirta they are ſomewhat longer, and not ſo perfectly heart ſhaped. In the odorata the bractes are placed above the middle of the ſcape or peduncle; in the hirta they are ſituate below it! But this character muſt be obſerved when the flowers of each are fully expanded, for the ſcape of the odorata above the bractes is conſiderably elongated, as the flowers fade. Theſe appear about a week later than thoſe of the odorata, are of a paler blue, and have none of that fragrance which renders the odorata ſo grateful a harbinger of ſpring. Beſides the perfect flowers which firſt ſpring up, the hirta continues for a month or more to throw out others, which have no petals or only rudiments of them, which never appear beyond the calyx; but theſe produce ſeed as well as the others. It is the ſame in the odorata, but in a leſs degree; and the capſules in both, when they become nearly ripe, lie cloſe to the ground: ſo that when they burſt, the ſeeds have an eaſy acceſs to the earth. Laſtly, there is ſome difference reſpecting the ſoil and ſituation; the odorata grows generally under warm hedges, among buſhes, or in woods; the hirta is pretty much confined to a calcareous ſoil, and often occurs in more expoſed ſituations. It is by far leſs frequent than the ſweet Violet. Long ſince obſerved about Charlton, in the way to Lewiſham, and near Sittingbourn in Kent. By North Cray Church, in many places about Foot's Cray, near Northfleet, and in the wood near Purfleet, by Mr. J. Sherard. In ſeveral places of Eſſex, and on the road from Aſhley to Silverton Steeple, on the confines of Cambridgeſhire towards Suffolk, by Mr. Dale. In coppices of Oxfordſhire, Shotover-hill, Stow-wood, Magdalen College woods [h]. Dr. Sibthorp marks it in the coppice under Shotover hills, and in Cheyney lane. Moor Barns, Cherry Hinton, &c. in Cambridgeſhire. At Marham in Norfolk, by Mr. Crowe. Near Bury in Suffolk, by Mr. Woodward. On Barton hill, Bedfordſhire, by Dr. Abbot. On St. Vincent's rocks near Briſtol, by Mr. Dyer. It flowers in april or may.

10. This has a large yellow flower, with bay-coloured veins. Native of Terra del Fuego, in boggy places [i].

11. Root fibrous, whitiſh: in old plants the upper part becomes knobby, and appears above ground, the knobs being formed from the baſe of the petioles which are left yearly; from the boſom of theſe knobs ſpring the ſcions or runners which creep on the ground, and are furniſhed with leaves and the ſame kind of ſtipules which are obſervable at the bottom of the plant: theſe runners are very long, and in general do not produce flowers till the ſecond year. Leaves ſomewhat rounded at the tip, notched at the edge, on the upper ſide ſmooth and ſhining, underneath ſlightly hairy, when young rolled in at the edges on longiſh upright nearly ſmooth footſtalks, which ſometimes however have a few ſcattered hairs. Stipules from the ſtump of the root in pairs, lanceolate, toothed, pale; each tooth terminates in a minute gland. Flower-ſtalks ſpringing from the root, taller than the leaves, ſmooth, bearing a pair of narrow bractes, preſſed to the ſtalk, and placed above the middle of it. Linneus remarks, that below the bractes they are quadrangular, and above them grooved on the upper ſide. They are incurvated at top, and ſupport one nodding flower. Calyx ſmooth, greeniſh purple. Corolla dark purple, varying to red purple, pale fleſh colour and white, poſſeſſing a fragrance generally moſt grateful. Spur ſhort and blunt: the two ſide petals marked with a hairy line on the inſide. Filaments very ſhort, flat. Anthers orange-coloured, dilated, cloſe but ſcarcely connected: from the back of two of them ſprings a ſlender flat greeniſh appendage, which enters the nectary. Style ſlendereſt at bottom and a little twiſted. Stigma hooked, and a little longer than the anthers. Seed-veſſel purpliſh, villoſe: containing ſeveral roundiſh, ſtraw-coloured ſeeds [k].

The accurate Gærtner, deſcribes the capſule as ſubglobular, rounded-three-cornered, one-coloured. Seeds to each valve about five, ovate-globular, of a dirty whitiſh colour, twice as big as in the tricolor. Navel large, glandular, elongated into a thick peduncle downwards, and produced upwards into an awl-ſhaped apophyſis lying on the ſeed. Coat cruſty, brittle. Embryo nearly the length of the albumen, graſs-green, or the radicle only green and the cotyledons yellow.

This favourite flower, ſo highly eſteemed for its fragrance, is a native of every part of Europe, in woods, among buſhes, in hedges and on warm banks; flowering in march and april; and ripening its ſeeds towards the end of ſummer. I gathered a handful of the flowers from a ſingle plant this year (1804) at the end of november. Desfontaines ſays it is frequent about Caſſa and Tozzer in Barbary, in the Palm groves; the

[h] Plot, Raii hiſt. and ſyn. Merr. pin. [i] Forſter. [k] Smith brit. and engl. bot. Curtis.

blue

Digitized by Google

blue and white growing promiſcuouſly, and flowering in winter. Haſſelquiſt found it in Paleſtine. Thunberg in Japan, plentifully by way ſides, flowering from january to april. Loureiro, in China near Canton.

The flowers of Violets, taken in the quantity of a dram or two, act as a mild laxative, and are given to young children in the officinal preparation of a ſyrup. This ſyrup is very uſeful in chemiſtry, to detect an acid or an alkali; the former changing the blue colour to a red, and the latter to a green: for this purpoſe Violets are cultivated in large quantity at Stratford upon Avon. Slips of white paper ſtained with the juice of the petals, and kept from the air and light, anſwer the ſame purpoſe. The ſeeds are reported to be ſtrongly diuretic, and uſeful in gravelly complaints. The powdered root in doſes from forty to eighty grains, vomits and purges [l].]

β, γ. Of the Common Violet there are the following varieties: the ſingle blue, and white, the double blue and white, and the pale purple. Theſe are all commonly preſerved in gardens, for the odour of their flowers. [It is very common with white flowers in the chalky ground near Cambridge. And Dr. Withering ſays, all that he has ſeen wild about Birmingham are white, with the ſame fragrance as the blue, but without the hairs on the inſide of the claws which that has.—It has been found wild with double flowers. This variety is in much eſteem, both for the ſuperior ſize of the flowers, and their extreme fragrancy: they alſo appear later and thereby keep up the ſucceſſion.

12. Root creeping, whitiſh, toothed, ſomewhat fleſhy, with many fibres. Leaves cordate-reniform, tender, ſhining, ſpreading, crenate, veiny, often purple beneath, on ſmooth ſemicylindric foot-ſtalks. Stipules radical, numerous, ovate, acute, ſmooth, ſcarcely perceptibly ſerrate. Flower-ſtalks longer than the leaves, erect, ſquare, ſmooth; having a pair of lanceolate erect bractes about the middle, not always below the middle, as Mr. Curtis aſſerts they are. Flowers ſolitary, drooping, inodorous, paler and ſmaller than in the more common ſpecies; ſometimes fleſh-coloured with darker red veins. Calyx-leaves rather elliptical, ſlightly membranous at the edge. The two upper petals are ſcarcely ſtreaked at all, the two lateral ones have one dark longitudinal line, and are bearded with white near the baſe; the lowermoſt is beautifully marked with numerous branched ſtreaks, and terminates behind in a ſhort blunt ſpur. Anthers bordered with an orange-coloured membrane, though collected together yet ſcarcely united. Stigma acute, with a ſingular protuberance above it [m]. It is diſtinguiſhed by this circumſtance from the other ſpecies, alſo by the greater roundneſs of its leaves, the paleneſs of its flowers, and its place of growth in bogs, or the moiſt parts of ſandy or turfy heaths. Like the odorata, hirta, &c. it produces ripe ſeeds without perfect flowers, and that in a greater quantity and for a longer continuance [n].

Native of Europe and Japan. With us more frequent in Scotland and the North of England than in the South: yet it is found plentifully on the boggy part of Shirley common near Croydon: it was gathered in Norfolk by Mr. Dawſon Turner; near Ampthill by Dr. Abbot; and long ſince by Dr. Plot on the banks of the Cherwell between Oxford and Water Eyton, by Dr. Richardſon on Oakenſhaw-moor and Roadeſhall woods, and by Mr. J. Sherard in the bogs about a mile from Joan Coles. On the borders of the lake weſt of Ballynahinch, in Ireland, by Mr. Templeton.

β. The variety with red ſtriped flowers mentioned by Parkinſon, was found in Yorkſhire by Mr. Stonehouſe, a reverend Miniſter of Darfield in Yorkſhire. The leaves were rounder and thinner, and the flowers reddiſh with ſadder veins therein [o].

It ſhould ſeem by the coloured copies of the Flora Danica to be intended by t. 83 of that work, though the leaves are there repreſented leſs pointed or more truly kidney-ſhaped than ours [p].

13. Root ſomewhat woody. The firſt flowers radical, but ſeveral branched angular leafy ſtems ſoon ſpring forth, which continue growing and bearing numerous flowers for ſeveral weeks. Leaves heart-ſhaped or oblong, crenate, ſmooth; their footſtalks ſmooth, ſomewhat dilated at the top. Stipules fringed. Flower-ſtalks axillary, ſolitary, erect, ſquare, bearing two awl-ſhaped bractes in the upper part, and one nodding blue flower. Anthers ſcarcely cohering. Calyx-leaves acute. Stigma gibbous. Capſule rather more oblong than in the Sweet Violet. Seeds roundiſh [q], of a pale yellowiſh colour, in each valve ſeven or nine.

Dog's Violet differs from the Sweet one in the flowers having no ſmell, being generally larger, and growing from the ſtem; the ſtipules very ſtrongly edged with ſtiff hairs; the calyx-leaves pointed; the ſeed-veſſel more oblong. It differs from V. hirta in all theſe reſpects except the firſt. It produces ſeed like them during the ſummer months, without any expanded corolla [r].

Native of Europe and North America.—After the flowers of the Sweet Violet are gone, every coppice, heath, hedge bank and ſhady dell is decorated for two or three months, with the paler and leſs welcome bloſſoms of the V. canina. This epithet ſeems to have been given it, as to the hedge roſe, to expreſs a degree of inferiority.

This ſpecies varies in the colour of its flowers, in the ſize of the whole herb, and in the form of the leaves [s]. Hence the varieties β, γ, δ.

β. Dog's Violet is not unfrequent with a white flower, and ſometimes the ſpur only is white [t].

γ. Mr. Du-Bois obſerved about Mitcham in Surry a variety ſmaller in all reſpects, with the ſpur of the flower yellowiſh [u].

The leaves are very ſmall, the largeſt not exceeding half an inch in length, and one third of an inch in breadth; others on the plant are even much ſmaller; they are more rough than in the common ſort. Stipules not ſo much fringed. Not entirely without ſtem, but it is very ſhort, and there is ſeldom more than one flower. It is common on heaths, and may be traced up through all its ſtages to the largeſt plant of V. canina [x].

δ. The Alpine variety was obſerved in Wales by Mr. Lhwyd. Dr. Richardſon, to whom he ſhowed it, did not think it different from the common Dog's Violet [y]. Yet Hudſon, in the firſt edition of his Flora, made it a diſtinct ſpecies, under the name of V. alpina or Welch Violet, with the character of a ſubtriflorous ſtem, and cordate leaves deeply ſerrate. But he does not aſſign any place of growth of his own knowledge. Dr. Smith only adopts it from Hudſon, not as a ſpecies, but a variety.

14. The herb in all its parts much ſmaller than the canina, and quite ſmooth. Stems procumbent at the baſe, and throwing out radicles from the joints, then erect, round, branched, leafy. Leaves alternate, on footſtalks about their own length, generally erect, lanceolate or inclining to ovate, decurrent, not cordate at their baſe, veiny, crenate, rather obtuſe. Stipules deeply ſerrate, and often pinnatifid; the ſerratures glandular not briſtly at the tip. Peduncles axillary, ſolitary, erect, riſing as high as the branches, each bearing above its middle a pair of purpliſh lanceolate bractes, moſtly toothed near their baſe, and at the top one nodding flower. Calyx-leaves linear-lanceolate, acute. Petals cream-coloured, obtuſe, much narrower than in V. canina, ſtreaked, eſpecially the lower one with purple lines, diſpoſed as thoſe in V. canina, and the two ſide petals, as in that, hairy above the baſe; ſpur ſhort and blunt. Anthers terminating in a broad dilated membrane, and not cohering. What diſtinguiſhes this from canina is principally the narrow and lanceolate form of the leaves, which if permanent would be ſufficient, but in cultivation the leaves become cordate; the flowers alſo turn blue. The ſtipules appear to be more deeply cut; and the bractes, which are entire and almoſt ſetaceous in canina, are in this lanceolate and moſtly toothed.—After all it is very doubtful whether it be any thing more than another variety of canina. It ſeems to be different from V. pumila of Villars. 2. 666.

[l] Woodville and Withering. [m] Smith brit. and engl. bot. [n] Curtis. [o] Park. theat. [p] Engl. bot. [q] Smith brit. and engl. bot. [r] Curtis. [s] Engl. bot. [t] Withering. [u] Dill. in Ray ſyn. [x] Woodward Mſſ. [y] Ray ſyn.

Digitized by Google

Mr. T. F. Forſter, jun. found it on the wolds near Tunbridge wells; and Mr. Stackhouſe at Pendarvis in Cornwall. It flowers in may [z].

15. Height about half a foot. Leaves large, oval-lanceolate, a little cordiform at the baſe. Flowers on axillary peduncles, bright blue, moderately large [a].

Stem tender, erect, a foot or even eighteen inches high, leafy and branched. Leaves petioled, the lower roundiſh or ovate, crenate, the upper elliptic. Stipules very large, ſemipinnate; the extreme pinna largeſt, oblong. Petioles long, erect, with very large lanceolate briſtles. Upper petals blue, middle ones pale, bearded, loweſt with a broad yellow claw with deep blue lines; ſometimes the flower is wholly blue, and ſometimes moſt of it is yellow: ſpur ſhort. Inodorous [b].]

Miller ſays it riſes with erect ſtalks more than a foot high; that the flowers are produced upon long axillary peduncles, are ſhaped like thoſe of the Dog Violet, of a pale blue colour, appear at the end of may, and are ſucceeded by roundiſh capſules filled with ſmall ſeeds which ripen in auguſt.

[It is improperly named arboreſcent by Camerarius, having nothing woody about it.

Cultivated in 1714, [c] in Chelſea garden.

16. Stem herbaceous, flexuoſe, grooved and angular, ſimple, hiſpid, a foot high and more. Leaves alternate, acuminate, wrinkled, ciliate, pale green; not unfrequently ſharply toothed and lacerated. Petiole very ſhort, ſemicylindric. Stipules four, two larger and two ſmaller, bowed, entire, ciliate. Peduncles two, very ſmall, from the axils of the leaves; one bearing an abortive flower. Bractes two, very ſmall, linear, obtuſe. Flowers ſmall, pale green of the ſame colour with the plant, whence its trivial name. Calyx five-leaved, concave, hooked. The two upper petals very ſmall, linear, recurved, entire; the two lateral linear, toothed, recurved; the loweſt two-parted; ſpur very ſhort, blunt. Stamens awl-ſhaped, very ſhort. Anthers green-purple, biſid at the baſe. Piſtil ſhort: ſtigma not urceolate but hooked, perforated, twice as long as the anther.

Native of North America, in bogs [d].

Mr. Forſter, who has cultivated this above fourteen years in his garden, informs us that it flowered only twice in that time. This gentleman having ſtudied the genus with great aſſiduity, and remarked not fewer than ſixty ſpecies, it is much to be wiſhed that he would give the reſult of his labours to the world.

17. This is a very ſmall plant, three or four inches high, with the peduncles two thirds of its length. Root black and knobbed. Leaves almoſt round, with a ſcarcely viſible point, and a ſtill ſmaller notch at the baſe, petioled, and only three or four lines in diameter: at their baſe are two lanceolate ſtipules, ſharply toothed. Flower ſmall, nodding, pale blue or whitiſh; with a blunt ſpur, half the length of the calyx [e].

Willdenow ſays it differs from the cenifia in having cordate leaves ſmooth at the edge, and toothed ſtipules.

Native of the alps of Dauphiné and Piedmont.]

18. This is an humble plant, with entire leaves, not more than half an inch long, and a quarter of an inch broad, on ſhort footſtalks. Flowers large, of a light blue colour, appearing in june, and having no ſcent.

[Stems filiform, perennial, undivided, creeping on under ground, aſcending at the top, quite ſimple. Leaves very ſmall, ſmooth, crowded at the top of the ſtem. Peduncle ſolitary, long. Flower large, blue, with a ſpur ſhorter than the petals [f].

Native of Mount Cenis and other places in the Alps. Mr. Miller received it from Dr. Allione, and cultivated it in 1759.

19. Stem a ſpan high. Leaves alternate, reniform-cordate, ſerrate, even, pale beneath, on petioles ſhorter by half than the leaf, in the uppermoſt yet ſhorter. Stipules in pairs, erect, lanceolate, ſhrivelling. Peduncles from each axil, ſolitary, naked, the length of the leaves. Flowers corolled. It differs from mirabilis in having the leaves more mucronate, the flowers on the ſtem corolled, the ſtems firmer and bigger [g].

Native of North America. Introduced in 1783, by Mr. William Young.

20, 21. Theſe alſo are natives of North America, and were introduced in 1772, by Mr. William Young. They all flower in june [h].

22. Leaves large, ſomewhat rigid, roundiſh, eſpecially the lower ones, produced at the end into a bluntiſh point, crenate with blunt broadiſh notches, on the upper ſurface a few ſlender hairs, paler beneath and ſmooth, on long thick petioles. The flowers come out early in ſpring among the young leaves, they ſmell ſweet, and are ſomewhat larger and paler than thoſe of V. odorata; though they have all the parts of fructification, yet they very ſeldom produce capſules: theſe are produced at the top of the ſtem after the flowers are paſt, among the leaves, on ſhort peduncles; they are large, oblong, ſmooth, pale green, bluntly three-ſided, filled with round pale ſeeds. This ſtem riſes to a long ſpan in height, is three-ſided, ſmooth, and has a few leaves on it, eſpecially at the top. Calyxes in both ſorts of flowers compoſed of five leaves, three larger, and two ſmaller or narrower. Petals commonly wanting in the upper fertile calyxes, but they have the piſtil and five ſtamens with their anthers.

It differs much from V. odorata, in having a ſtem, larger and longer capſules, wider leaves, more produced, and with broader notches; it does not creep by runners, and the capſules, when they are produced next the root, do not lie on the ground, but ſtand up. It is not unlike V. hirta, eſpecially in the leaves; but in that the leaves and petioles are very hairy, the former are paler with ſmaller notches, the flowers alſo are paler and ſmaller than in this, the capſules are round and hairy, and it has no ſtem.

This ſpecies was firſt obſerved by Maurice Hoffman, who (in Fl. Alt. 63.) calls it Viola ananthos, ſtamine perpuſillo luteo, cui capſula oblonga triangula ſuccedit. It is noticed in Ruppius's Flora Jenenſis; and was communicated to him by Dillenius, who found it in Hangeſtein wood, about a mile from Gieſſen his native place, and introduced it into the Eltham garden [i]. It was afterwards found by Linneus about Upſal, in Oeland and Dalecarlia, and by others in Germany, Auſtria, &c.

A ſingular œconomy having been firſt remarked in this ſpecies, gave occaſion to its being named mirabilis; but it has ſince been found to take place in ſeveral other ſpecies, as hirta, odorata, and montana. Jacquin ſays that the barreneſs of the corollate flowers in the mirabilis appears to ariſe from a defect in the ſtyle.

23. This is a very tender plant. Stem a hand high, from decumbent erect, ſmooth, round below but flatted above. Leaves petioled, ſmooth and even. Stipules oblong, acute. Peduncles two, filiform, compreſſed a little, one terminating, the other axillary. Bractes two, alternate, ſmall, preſſed cloſe. Corollas yellow, the claws of the petals with dark veins [k].

Leaves, according to Haller, reniform without a point, roundly and minutely ſerrate, ſubhirſute, on long petioles. Upper calyx-leaf very ſmall, the middle ones very large. Flowers ſmall, the four upper petals yellow with rufous lines, the loweſt deep orange with black lines.

Native of the Alps of Europe. Cultivated by Mr. Miller in 1739. (vol. 2, n. 12.) It flowers in april and may [l].

24. Stem ſcarcely a ſpan high, naked, firm, bearing at the top three ſubalternate cordate toothed ſubvilloſe leaves, on very ſhort petioles. Flower one, yellow, bigger than the leaves, on a very ſhort peduncle. Native of Siberia [m]. Cultivated in 1774, by Mr. James Gordon. It flowers in june and july [n].

25. Stems decumbent, filiform, ſomewhat branched, ſcarcely fruteſcent. Leaves linear, ſomewhat cluſtered, an inch long, quite entire, acute, ſeſſile. Stipules minute, awl-ſhaped, acute. Peduncles ſolitary, longer than the leaves, axillary. Bractes in pairs, minute, on the middle of the peduncle. Corolla blue, ſpurred, very nearly allied to V. tricolor. Native of the Cape of Good Hope [o].

This and all the preceding ſpecies are perennial.

[z] Smith brit. and engl. bot. [a] Villars. [b] Haller. [c] Hort. kew. [d] Forſter. [e] Villars. [f] Linn. ſpec. [g] Idem. [h] Hort. kew. [i] Dillenius. [k] Krocker. [l] Hort. kew. [m] Linn. ſpec. [n] Hort. kew. [o] Linn. ſuppl.

Digitized by Google

26. Root annual, ſimple, fibrous. Stems aſcending, much branched. Stipules pinnatifid, with two or three pairs of ſhort linear pinnæ at the baſe, and a large elliptical one ſlightly toothed terminating. Leaves elliptical or lanceolate, ſerrate, or toothed. Peduncles axillary, ſolitary, longer than the leaves; lower ones ſpreading, ſometimes declining; with a pair of ſmall bractes a ſhort diſtance below the flower. Calyx-leaves acutely lanceolate, unequal, the three upper ſhorteſt, but longer than the upper petals; the two lower as long as the lower petal: all remaining and ſurrounding the capſule [p]. This is of an oblong ſpheroidal form, with ſix longitudinal bands, of different colours, namely whitiſh, ruſeſcent, or green, one-celled, three-valved; the valves at firſt concave, afterwards boat-ſhaped, converging, and throwing out the ſeeds. Theſe are numerous, (more than 30,) ovate-acuminate, ſmooth and ſhining, pale ſtraw-coloured or whitiſh; they are faſtened in longitudinal rows by means of ſhort pedicels to the middle of the back of the inner ſurface of the valves. They are covered with a ſingle thin papery coat. Albumen fleſhy, thick, white. Embryo almoſt the length of the albumen, of a graſs-green. Cotyledons orbicular, flattiſh. Radicle a little longer than the cotyledons, ſtraight, roundiſh, centrifugal [q].

The ſtem is about four or ſix inches high, angular, pubeſcent, at bottom of a dull purple colour: branches alternate, erect. Leaves alternate, petioled, hairy eſpecially about the edge, but ſometimes ſmooth; the lowermoſt often ſmaller and roundiſh, the uppermoſt narrow and ſlightly indented. Peduncles alternate, nearly quadrangular, channelled on the back, bent in at top. Petals obcordate, ſhorter than the calyx and whitiſh or yellow white, in its truly ſavage ſtate, when it appears as a weed among corn: but longer than the calyx, and variegated with yellow and purple in gardens [r]. The truly wild plant has ſometimes a few purple ſtreaks: and in a ſomewhat improved ſtate is blue or purpliſh, with or without yellow or white [s]. Theſe go under the name of V. bicolor.

β. With more than two colours, purple, blue, yellow, white, improved and enlarged by garden culture. Linneus remarks the black lines which ſometimes appear on the petals; and gave occaſion to Milton's expreſſion of "Panſies freakt with jet."]

Some of theſe varieties, ſays Mr. Miller, have very large beautiful flowers, with an agreeable odour; others have ſmaller flowers without ſcent. Some have the two upper petals of a deep yellow colour with a purple ſpot in each, the two middle of a paler yellow with a deep yellow ſpot, and the lower petal like velvet; in others the petals are white with yellow and purple ſpots; in ſome the yellow is the moſt prevailing colour, in others the purple.

[The variation from white to purple in this flower, gave occaſion to Shakſpeare, in his Midſummer Night's Dream, to feign a metamorphoſis of it, and at the ſame time to pay an elegant compliment to Queen Elizabeth.

"Yet mark'd I where the bolt of Cupid fell;
"It fell upon a little weſtern flower,
"Before milk-white; now purple with Love's wound,
"And Maidens call it Love in idleneſs."

It has ever been a favourite flower with the people, and has many provincial names bearing ſome alluſion to love: as that juſt mentioned; Kiſs me behind the garden gate; Call me to you; Three faces under a hood; in days of ſuperſtition it was called Herb Trinity, for an obvious reaſon ſuch as it was. Heart's-eaſe is the general name by which it is now known, and that ſhows the eſteem in which it is held. Its more elegant name Panſies is from the French Penſees. The meaning is alluded to by Shakſpeare in Hamlet. "There's Panſies, that for thoughts."— Gerarde's names are Hart's eaſe, Panſies, Live in idleneſs, Cull me to you, and Three faces in a hood.

Native of Europe, Siberia and Japan: in corn fields, gardens, &c. flowering from may to ſeptember; frequently earlier and in mild ſeaſons much later.

[p] Woodw. Mſſ. [q] Gærtner. [r] Smith and Curtis. [s] Withering.

Heart's eaſe was repreſented by old writers on the materia medica as a powerful medicine in epilepſy, aſthma, ulcers, ſcabies and cutaneous complaints. Stark, Metzger, Haaſe and other moderns recommend it eſpecially as a remedy for the cruſta lactea. For this purpoſe, a handful of the freſh herb, or half a dram of it dried, and boiled two hours in milk, is to be ſtrained and taken night and morning. Bread with this decoction is alſo to be formed into a poultice, and applied to the part. By this treatment it has been obſerved, that the eruption during the firſt eight days increaſes, and that the urine, when the medicine ſucceeds, has an odour ſimilar to that of cats; but on continuing the uſe of the plant a ſufficient time, this ſmell goes off, the ſcabs diſappear, and the ſkin recovers its natural purity.

Inſtances of the ſucceſsful exhibition of this medicine, as cited by theſe authors, are very numerous. It appears, however, that Murſinna, Ackermann, and Henning were leſs fortunate; and the laſt of them declares, that in the different cutaneous diſorders in which he uſed it, no benefit was derived.

Haaſe, who adminiſtered it in various forms and large doſes, extended its uſe to many chronic diſorders; and from the great number of caſes in which it proved ſucceſsful, it ſeems to deſerve a farther trial in this country [t].

27. Stem high, branched, leafy, ſtipuled, altogether that of V. tricolor, but the flower is very large and yellow, with ovate petals, the length of the leaves, and a ſpur twice as long as the calyx, but ſhorter than the petals [u].

Linneus at firſt conſidered it as a variety of the calcarata, but afterwards ſeparated it, though he ſtill conſidered them as too nearly allied, and both as the progeny of V. tricolor: which is annual, whereas theſe are perennial.

Villars deſcribes the root as creeping; the ſtems from five or ſix inches to ten in height; the leaves as oblong, obtuſe, and entire from the bottom up to the middle, whence iſſue two or three naked peduncles, each bearing one flower. The ſtipules are intermixed with the leaves, as in the calcarata, but they are larger and more cut. The flower is of three colours, but the yellow predominates. The ſpur is as long again as the calyx: in the calcarata it is twice as long.

Native of Switzerland, Sileſia, Dauphiné, and the Pyrenees.

28. Root perennial, ſmall, ſlender. Stem unbranched, weak and proſtrate at the baſe, then erect or aſcending, leafy, triangular, very ſlightly downy, bearing one or two flowers on very long ſtalks from the boſoms of the upper leaves. Leaves alternate, petioled, more or leſs ovate, crenate, very like thoſe of the tricolor, but finely fringed; accompanied by a pair of large, deeply five-cleft, fringed ſtipules, the outer lobes of which are deepeſt and narroweſt. Calyx toothed at the baſe. Petals either all yellow with dark purple radiating veins, or the two uppermoſt blue purple and the reſt yellow with a blue tinge, or ſometimes wholly purple. Anthers ſlightly attached to each other. The ſtyle and ſtigma are of a ſingular form, and the purple line under the ſtigma is remarkable [x].

This ſpecies, which has been confounded with V. tricolor, differs widely from it in its place of growth, in being perennial, in having a ſimple ſtem, and the ſtipules deeply five-cleft and palmate, neither pinnatifid nor lyrate, though the middle lobe is larger than the reſt [y].

It has been confounded alſo with the preceding, but that has a much larger flower, and differs both in the ſpur and ſtipules. Our plant was entirely unknown to Linneus [z].

Our lutea is thus accurately deſcribed by Mr. Woodward under the name of grandiflora, from plants growing in great abundance on the hills above Dovedale in Derbyſhire. Stem erect, or aſcending, three-angled, ſimple. Stipules in pairs with winged cleſts, linear or linear-lanceolate, the terminating one not much longer than the others, all abſolutely entire, ſlightly

[t] Woodville. [u] Linn. mant. [x] Smith brit. and engl. bot. [y] Engl. bot. [z] Withering.

hairy.

Digitized by Google

hairy. Lower leaves obtuſely ovate-lanceolate; upper elliptical or lanceolate, diſtantly ſerrate or toothed, ſlightly hairy. Fruit-ſtalk one terminating, and ſometimes one or two more ariſe from the axils of the upper leaves, pointing upwards, and nearly parallel to the upper one. Bractes ſmall, in pairs, at a little diſtance beneath the flower. Calyx-leaves lanceolate, unequal, all much ſhorter than the petals. Corolla yellow; two upper petals oval, tapering to a narrow claw, unveined; ſide ones oval, as broad but ſhorter than the upper ones, with three purple veins near the baſe, and fringed, terminated in a bent claw; lower one very broad, ſlightly emarginate, tapering to the baſe, and ending in a blunt horn longer than the calyx but ſhorter than the petals; this petal is marked with branched purple veins towards the baſe. Mr. Woodward ſuſpects this not to be diſtinct from V. tricolor, though it differs in three, and thoſe not trifling particulars: the ſimple ſtem, the ſhape of the ſtipules, and the comparative length of the calyx and petals. The few fruit-ſtalks and their manner of growth alſo diſtinguiſh it.

The ſtem of the tricolor, ſays Dr. Withering, is almoſt always branched, but this is never ſo, even in the ſtrongeſt and moſt luxuriant ſpecimens.

This ſpecies is found only in mountainous paſtures. It is plentiful in the north of England, Scotland, and the wildeſt parts of South Wales, often in a rotten peaty ſoil. Near Latham in Lancaſhire, found by Mr. Heſketh, according to Gerarde. Between Malham and Settle, and about Hallifax, Yorkſhire, found by Dr. Richardſon. About Attamine cliffs near Settle in the ſame county, by Mr. Curtis. Dovedale, by Mr. Woodward. Chatſworth park, by Mr. Whately. Moorlands of Staffordſhire, between Leek and Buxton, by Dr. Stokes. In Scotland, on Broughton-heights in Tweddale, and on Pentland hills, two miles ſouth of Faſt-caſtle, at Crawford-John, near the Lead-hills in Lanerkſhire, and with a purple flower on Mall-gyrdy, in Breadalbane, &c. by Lightfoot. It flowers from may to ſeptember.—Ray, in his hiſtory, has diſtinguiſhed this ſpecies very well from the grandiflora.

29. This reſembles the grandiflora, but it has a ſhorter ſtem, ſhorter leaves, and quite entire very ſhort ſtipules. The flowers are yellow with a blue ſpur. Hoſt has united it with the grandiflora, but it differs from that in habit as well as the marks ſpecified above. Native of the mountains of Carinthia [a].

30. Leaves near the root very ſmall and crowded, oval, obtuſe, toothed and petioled. The ſtipules mixed with the leaves are wide, of the ſame colour, but pinnatifid, ſeſſile and oppoſite; whereas the leaves are petioled and alternate. The two lower calyx-leaves are ſlightly cloven into two lobes at their hinder part and turned back. The flower is large, with a ſlender ſpur from three to ſix lines in length. It is ſometimes white, and ſometimes it is found with flowers ſmaller by half than common; but having the ſame ſmell and colour, the ſtem and leaves only a little increaſed in ſize [b].

According to others, and the ſynonyms, the flowers are blue, not yellow, but the colour is very uncertain in this ſection of the violet, and the ſpecies are ſo nearly allied as not eaſily to be diſtinguiſhed.

Linneus remarks, that what nature has taken from the herb of V. tricolor in this plant, it has added to the flowers.

Native of the Alps of Europe. Cultivated by Mr. Miller in 1739: (vol. 2. n. 11.) It flowers in march [c].

31. This differs from the preceding, in having a long erect ſtem, whereas that is in a manner ſtemleſs; this has oblong petals leſs than the leaves, in that they are round and bigger than the leaves; in this the leaves are oblong-ovate, in that rounded-ovate; yet after all they are very nearly allied [d].

According to Desfontaines, the ſtems are decumbent at the baſe, ſtriated, ſmooth; the leaves obtuſe, crenate, ſmooth, on petioles longer than the leaves; the ſtipules pinnatifid at the baſe; the peduncles long, one-flowered; the flower of the ſame ſize with that of the garden V. tricolor, violet or white; the ſpur awl-ſhaped, the length of the flower.

Native of the Pyrenees. Ray found it on mount Jura; but Haller ſays it has not been found by any other perſon in Switzerland. Desfontaines obſerved it in mount Atlas near Belide, belonging to the Algerines.

Introduced in 1776, by Caſimer Gomez Ortega, M.D. It flowers in may [e].

All theſe are perennial, and differ in that reſpect from V. tricolor.

Desfontaines has a ſpecies, which he entitles Viola ſuberoſa, and characterizes as ſuffruticoſe, with narrow-lanceolate, ſerrate, ſmooth leaves, awl-ſhaped ſtipules, axillary peduncles, and a very ſhort ſpur. The bark in very old trunks is cloven and fungous. Branches round, ſlender, unequal, leaflets at bottom decumbent, tubercled. Leaves at the end of the branches cluſtered, running down into a ſlender petiole. Stipules entire. Peduncles ſolitary, filiform, one-flowered, for the moſt part longer than the leaf. Calyx-leaves linear, acute. Corolla the ſize of V. biflora, pale blue or white, with a blunt ſpur. Style longer than the ſtamens. Stigma hooked. Native of mount Atlas, in the cleſts of rocks.

32. Native of the Cape of Good Hope.

33. Native of Spain. Theſe are both ſhrubby. This was introduced in 1784, by Mr. John Fairbairn [f], gardener of the botanic garden at Chelſea.

34. Native of the Weſt Indies, in the iſland of St. Chriſtopher [g]. Perennial.

35. Root perennial, cylindric, thickneſs of a pigeon's quill, flexuoſe, toruloſe, aſh-coloured. Appearance that of Veronica ſerpyllifolia. Stems ſcarce a foot high, diffuſed, ſomewhat twining, filiform, branched at the baſe, afterwards ſimple, ſubpubeſcent. Leaves on the ſtem and branches numerous, approximating, having five ſerratures on each ſide, blunt, flat, ſmooth, veined, the ſame ſize as thoſe of Vaccinium Vitis idæa. Peduncles axillary over the whole ſtem, ſhorter by half than the leaf, ſolitary, erect, naked, one-flowered. Flower the ſmalleſt of all the Violets. Capſule ſmall. This ſpecies has roots in habit and property very like thoſe of Ipecacuanha. Native of the hotter regions of South America, where it was found by Mutis [h].

36. Root perennial. Stem ſcarcely branched except at the baſe, where it is very much ſo, half a foot high, with rudiments of branches in the axils. Leaves ſcarcely petioled, alternate; without any ſtipules. Peduncles axillary, capillary; ſolitary, one-flowered. Calyx-leaves not at all appendicled at the back. Lower lip of the corolla wide, it is the upper and not as in the reſt reſupine downwards [i]. According to the Hortus Malabaricus there are eight ſhining ſeeds in the capſule.

Burmann ſays the flowers are blue and ſoon fall off.

Native of the Eaſt Indies.

37. Stem a ſpan high or little more, not much branched, ſmooth. Leaves ſeſſile, remote, the lower oppoſite, the upper alternate, ſcarcely an inch long, very ſmooth, paler underneath, bluntiſh, for the moſt part quite entire, but ſometimes having one or two remote ſerratures. Stipules two on each ſide, briſtle-ſhaped, ſpreading. Peduncles one-flowered, the lower oppoſite, the upper alternate, twice or thrice as ſhort as the leaf, filiform, jointed above the middle, below the joint permanent like a thorn after the flower is fallen. Bracte minute, towards the baſe of the peduncle. Calyx equal behind: calyx-leaves lanceolate, attenuated, whitiſh at the edge. Lower petal linear. It differs from V. enneaſperma in having a ſuffruticoſe ſtem, and quite entire leaves:—from V. ſuffruticoſa in having remote oppoſite leaves. Found by Weſt in the iſland of Santa Cruz [k].

38. Herb procumbent, very much branched, hard as in Helianthemum. Leaves alternate, acute, ending in the petioles, ſcarcely manifeſtly ſerrate. Stipules awl-ſhaped, hardiſh, permanent; whence the plant is rugged and in a manner prickly. Peduncles capillary. Flower as in n. 36 [l]. Native of the Eaſt Indies.

39. This riſes with ſeveral upright, branchy, villoſe ſtems, with alternate, downy, grayiſh leaves: the

[a] Willdenow. [b] Villars. [c] Hort. kew. [d] Linn. ſpec. [e] Hort. kew. [f] Hort. kew. [g] Swartz. [h] Linn. ſuppl. [i] Linn. zeyl. [k] Vahl. [l] Linn. zeyl.

flowers

flowers are axillary and ſolitary, and either of a white or blue colour: the fifth petal is very large and rhomboid. It is a native of the Caribbee iſlands, flowering at various times of the year [m].

Native of Cumana, Cayenne and Martinico.

40. Shrubby, with a ſmooth ſtem. Native of Cumana. This and the preceding were found by Loefling, and ſuppoſed by him to belong to the genus Calceolaria.

41. This is an inelegant little tree, upright, branched, about ſeven feet high. Prickles awl-ſhaped, ſcattered, few. Leaves attenuated to both ends, emarginate, ſlightly ſerrate, petioled, coming out ſeveral together from the ſame tubercle. Common peduncles ſhort, bifid at top, few-flowered, one or two from the ſame tubercle with the leaves. Flowers ſmall, inodorous, with whitiſh corollas, ſcarcely to be examined with the naked eye. Fruit the ſize of a large pea [n].

This differs from the Violets in having many-flowered peduncles. Jacquin at firſt made it a diſtinct genus. Native of South America.

42. Root fibrous, white, branched. Stems two feet high, erect, round, even, branched. Leaves alternate, petioled, elliptic, ſharply ſerrate, ſmooth. Petioles very ſhort. Stipules in pairs, ſcarioſe, lanceolate, keeled, awned, hairy. Flowers lateral, ſolitary, peduncled, drooping, on a peduncle ſhorter than the leaves. Bractes two, on the middle of the peduncle, very ſhort, lanceolate, hairy at the tip. Calyx five-leaved, muricate at the edge. Petals five, white; two ſhorter than the calyx, linear; two a little longer, reflexed, emarginate; one very large, retuſe, wide, gibbous at the baſe without a ſpur, pubeſcent beneath. Many contend that the root of this is the White Ipecacuanha. It certainly is not the brown [o]. See Pſychotria emetica. Native of Braſil.

43. Stem filiform, climbing along hedges by creeping. Leaves alternate, remote. Peduncles ſolitary, jointed, thickened; with two minute bractes on them. Calyx by no means protruded behind. Corolla white: upper petal incumbent, very large, as it were ringent with a trifid helmet; lateral petals aſcending; lower petals ſmaller, bent downwards; the uppermoſt of theſe ends behind in a very long twiſted nectary or ſpur. Stamens five, three of which are anterior and ſterile; the other two poſterior and fertile. Allamand [p].

PROPAGATION AND CULTURE.

1, 2. Theſe North American Violets will ſucceed beſt by putting them in pots filled with loam and bog earth mixed, and plunged in a north border, where they may be ſheltered in winter, or taken up, and kept in a common hot-bed frame.]

The common Violets are eaſily propagated by parting their roots; this may be done at two ſeaſons: the firſt or moſt common ſeaſon for removing and parting theſe roots is at michaelmas, that the young plants may be well rooted before winter; this is generally practiſed where the plants are put on the borders of wood-walks in large plantations, but in the gardens where they are cultivated for their flowers, the gardeners tranſplant and part their plants ſoon after their flowering ſeaſon is over; they gather all the flowers firſt, and the plants, which are then removed, having all the remaining ſummer to grow and get ſtrength, will produce a greater quantity of flowers the following ſpring, than thoſe which are removed in autumn; but this is not to be practiſed, where they cannot be ſupplied with water till they have taken new root, unleſs in moiſt ſeaſons.

When theſe are planted, they ſhould be placed at a good diſtance from each other to allow them room to ſpread, for if they are expected to produce many flowers, they ſhould not be tranſplanted oftener than once in three or four years, and in that time the offsets will ſpread over the ground, if the roots are three feet aſunder.

Violets may alſo be propagated by ſeeds, which ſhould be ſown ſoon after they are ripe, which is about the end of auguſt. The plants will come up the following ſpring, and when they are fit to remove, they ſhould be tranſplanted in ſhady borders to grow till autumn, and then they may be planted where they are to remain, but the double-flowering Violets do not produce ſeeds.

The other ſorts of Spring Violets are ſometimes preſerved in botanic gardens for the ſake of variety; theſe may be propagated in the ſame way as the common ſort, but require a moiſt ſoil and a ſhady ſituation.

The upright ſort not ſending out ſhoots like the common Violet, increaſes but ſlowly by offsets; this may be propagated by ſeeds in plenty, and is as hardy as the common ſort.

The ſeveral varieties of Panſies (n. 26.) will ſcatter their ſeeds in a ſhort time after the flowers are paſt, and from theſe ſelf-ſown ſeeds the plants which come up in autumn, will flower very early in the ſpring, and theſe will be ſucceeded by the ſpring plants; ſo that where they are indulged in a garden, and their ſeeds are permitted to ſcatter, there will be a conſtant ſucceſſion of their flowers the greateſt part of the year; for they will flower all the winter in mild ſeaſons, and moſt part of the ſummer in ſhady ſituations, which renders them worthy of a place in every good garden; but then they muſt not be allowed to ſpread too far, leſt they become troubleſome weeds, for their ſeeds, when ripe, are caſt out of their covers with great elaſticity to a conſiderable diſtance, and the plants will ſoon ſpread over a large ſpace of ground, if they are permitted to ſtand.

The great yellow Violet propagates by offsets in pretty great plenty, if it has a moiſt ſoil and a ſhady ſituation; this may be tranſplanted in autumn, and the offsets may then be taken off, but the roots ſhould not be divided into ſmall heads; nor ſhould they be too often tranſplanted, becauſe they will not produce many flowers unleſs the plants are ſtrong, and have good root in the ground. This ſort will not live in a dry ſoil, nor in a ſituation much expoſed to the ſun.

DESCRIPTIONS, &c.

1. Root annual. Herb tender, like that of Mercurialis annua. Stem round, a ſpan high or more, ſimple, ſometimes rooting, pubeſcent. Leaves oppoſite, petioled, ovate, obtuſe, quite entire, decurrent along the petiole, veined, ſmall. Stipules interfoliaceous, ſmall, erect, awl-ſhaped. Peduncle terminating between two tender branches, for the moſt part ſhorter than the leaves, two-flowered: the lower flower ſeſſile. Corollas becoming red, with a white mouth. Native of Surinam, in moiſt places; found by Dalberg [q].

2. Branches roundiſh, oppoſite, with cloſe-preſſed hairs, ſcattered over them. Leaves oppoſite, an inch long, acute at each end, quite entire, having cloſe-preſſed hairs ſcattered over them on both ſides, veinleſs, nerved, paler underneath, on very ſhort petioles, on each ſide of which is a ſhort lanceolate ſtipule. Peduncles from the uppermoſt axils and from the top, oppoſite. Flowers four to ſix, at the top of the peduncle, ſcarcely pedicelled. Calyx rough-haired, ſuperior: ſegments linear, ſharp. Tube of the corolla twice as long as the calyx, thinly hairy on the outſide, and the opening hirſute: ſegments of the border oblong. Germ crowned at the edge. Style thicker above, almoſt the length of the border. Stigma club-ſhaped. Native of Guiana [r].]

DESCRIPTIONS, &c.

1. This plant inſtead of rooting and growing in the earth, fixes itſelf into the branches of trees, where it ſpreads and forms a large buſh. The branches are woody, and are covered with a pale or yelloviſh green bark; the largeſt is about the thickneſs of a man's finger, and the reſt gradually ſmaller; they have many joints which eaſily part aſunder; and at each of theſe are two thick fleſhy leaves, which are broad and rounded at their points, and narrow at their baſe. The flowers come out from the axils in ſhort ſpikes, and are compoſed of four greeniſh-yellow calyx-leaves. The female flowers are ſucceeded by round white berries, which are almoſt pellucid, about the ſize of currants,

Digitized by Google

plants, full of a tough viſcid juice, in the middle of which lies one heart-ſhaped flat ſeed.

[The root inſinuates its fibres into the woody ſubſtance of the tree on which it grows. The ſtem is one of the beſt inſtances we have of what Linneus calls dichotomous, in its mode of branching. The branches are round, ſmooth and even: the leaves pale green, oppoſite, tongue-ſhaped, quite entire, ſmooth and even: the flowers in axillary ſeſſile heads, few together, inſerted into a fleſhy common receptacle [s]. Berry inferior, marked with four brown warts at the top from the falling of the capſule, ſpherical, white, diaphanous, one-celled: pulp viſcid, pellucid, ſurrounding the ſeed. Seed elliptic, as it were emarginate, and thence heart-ſhaped, or a ſpherical triangle, compreſſed like a lens, fleſhy, when freſh, painted with white dendritic veſſels on a graſs-green baſe: navel in the baſe of the ſeed, ſlightly emarginate [t].

Native of Europe and Japan, on various trees: flowering in may. It is very rare with us in the northern counties, and in Scotland not remarked at all. In the fruit counties, as Worceſterſhire and Herefordſhire, very common in orchards and hedge-rows.

Miſſeltoe, ſays Gerarde, groweth upon Okes, and divers other trees almoſt every where. Parkinſon reports that it groweth very rarely on Okes with us, but upon ſundry other as well timber as fruit trees, plentifully in woods, groves, and the like, in all the land. Both theſe authors hold the exploded notion of this paraſite growing from its own ſuperfluous moiſture, and not from ſeed.

Mr. Ray, in his Cambridge catalogue (1660) ſays it grows upon Apple trees chiefly, but that he has ſometimes found it upon the White-thorn. In his Hiſtory he relates that he has ſeen it upon the Maple and Aſh in Mr. Willughby's park at Middleton in Warwickſhire, on the Hazel near Braintree in Eſſex, on the Lime, Elm, Willow, Mountain Aſh and Buckthorn; on Apples, Pears, and White-thorn frequently, on other trees more rarely. John Bauhin enumerates many other trees on which he and others have obſerved the Miſſeltoe to grow as Cratægus Aria, Hornbeam, Birch, &c. Bartholinus ſays that he never obſerved it on the Almond, but it is commonly found in Provence, both on that tree and the Box; and John Bauhin ſays that he once obſerved it on the Almond. Braſſavola ſaw it on the Vine.

The Miſſeltoe of the Oak has been celebrated from the time of the Druids both as a ſacred plant, and as a medicine.

"Ad viſcum Druidæ, Druidæ cantare ſolebant."

And the Oak itſelf on which it grew was alſo held ſacred. The Druids ſent round their attendant youths with branches of the Miſſeltoe to announce the entrance of the new year; and this cuſtom has continued down to modern times, for in ſome parts of France the children run about from houſe to houſe aſking for Miſſeltoe in rude rhymes, and calling out *Aguilaneuf*, that is *A gui l'an neuf*, or *to the Miſſeltoe, 'tis the new year* [u]. And in England, branches of this plant are hung up in moſt houſes at Chriſtmas, among other evergreens.

As a medicine, the Miſſeltoe of the Oak obtained great reputation for the cure of the Epilepſy; and a caſe of this diſeaſe in which it proved remarkably ſucceſsful, is mentioned by Mr. Boyle [x]. Monſ. Villars adminiſtered the dry leaves in powder to two children between eight and ten years of age, who were epileptic, and were cured by it; but he has cured others by emetics and Cinchona; whilſt others again have reſiſted all theſe remedies, together with cauteries, ſetons, extracts of henbane and valerian, electricity, &c.

The wood raſped or powdered, from a dram to a dram and half in a doſe, or a decoction of it, from two drams to an ounce and half, is a very old remedy in the epilepſy; but it is now diſregarded, and its ſenſible qualities promiſe little [y].

The uſe of it however has been ſtrongly recommended in various convulſive diſorders by Colbach. He adminiſtered it in ſubſtance, in doſes of half a dram or a dram of the wood or leaves, or an infuſion of an ounce. This author was followed by others, who have not only borne teſtimony to the efficacy of the Miſſeltoe in convulſions, but alſo in complaints denominated nervous, in which it was ſuppoſed to act in the character of a tonic. But all that has been written in favour of this remedy, has not prevented it from falling into general neglect, and the Colleges of London and Edinburgh have expunged it from their catalogues of the Materia Medica [z].

There ſeems to be a diſpoſition to doubt, whether the Miſſeltoe ever grows upon the Oak. It is certainly not common now in England upon that tree, and I do not recollect having ſeen it more than once, which was many years ſince, in the Duke of Mancheſter's park at Kimbolton. The Engliſh Oak is of ſo hard a texture, that it is no wonder if the Miſſeltoe ſhould find a difficulty in eſtabliſhing itſelf upon it; eſpecially as few Oaks are now left to be in a ſtate of decay, when it principally attacks trees, and contributes to haſten their diſſolution. The ſcarcity of this paraſitical plant on the Oak at preſent, is no proof that it might not have been plentiful when great part of the iſland was a foreſt, and there were trees in all ſtates of age and decay adapted to receive and nouriſh it.

Ray ſays that the Miſſeltoe is very rarely found on the Oak in England; but according to Cluſius, it is very abundant on that tree in many woods of Hungary; and Bellonius writes, that between mount Athos and Ceres and Tricala there is not an Oak to be ſeen without Miſſeltoe on it; he affirms indeed that it is different from that which grows on Apple and Pear trees, but he does not inform us in what the difference conſiſts. Scopoli obſerved it on the Pine and the Oak in Carniolia. Pollich ſays, "circa Lauteren in ſylvis paſſim ad quercus præprimis reperitur." Allione relates, that it occurs on the Oak, as well as other trees, on the hills about Turin.

The berries of Miſſeltoe are devoured by ſeveral birds, as the Blackbird, Fieldfare, Thruſh, and large Thruſh thence named Miſſel Thruſh or Miſſeltoe Bird. Birdlime is made from theſe berries and alſo from the bark [a].] The berries are boiled in water till they burſt, when they are well beaten in a mortar, and afterwards waſhed, till all the branny huſks are cleared away.

The Italians make their birdlime of the berries heated and mixed with oil, as is alſo that which they make of Holly bark; and to make it bear the water, they add turpentine.

The birdlime now commonly uſed with us, is made of the bark of Holly, which is ſtripped off about midſummer: this is boiled for ten or twelve hours, and when the green coat is ſeparated from the other, it is covered up with fern for a fortnight, and put in a moiſt place; by that time the bark will be turned to a jelly, and no fibres left: then it is beaten in a ſtone mortar till it becomes a tough paſte: this is waſhed in a running ſtream till no motes appear; is then put up to ferment for four or five days, is ſcummed as often as any thing ariſes, and then laid up for uſe. When uſed, a third part of oil is incorporated with it over the fire. The bark of our Wayfaring Shrub, as it is ſaid, will make birdlime as good as that of the Holly.

That which is brought from Spain has an ill ſmell. Damaſcus birdlime is ſuppoſed to be made of Sebeſtens, their kernels being frequently found in it; but this will not endure either froſt or wet.

[Our Engliſh name is from the German *Miſtel*; it is the ſame in Swediſh: in Dutch, *Marentacken*: in French, *Gui*. The Italians have kept the Latin name, *Viſchio* or *Viſco*; the Portugueze, *Viſgo*. The Spaniards, *Liga*. The Japoneſe, *Kſei* or *Jadoriki*.

2. This Miſſeltoe, ſays Cateſby, has long ſmooth ſhining green leaves, growing by pairs: the berries are round, red, and ſomewhat ſmaller than thoſe of the Common Miſſeltoe: they grow in cluſters to ſtalks of above an inch long, which ſhoot forth by pairs from between the joinings of the leaves to the ſtalk. They grow to Mahogany and other trees of the Bahama iſlands.

3. The

Digitized by Google

3. The leaves of this ſpecies, according to Cateſby, grow by pairs, and are narrow at their beginning, and broad at their ends, ſet on ſlender pliant ſtalks, growing confuſedly, after the manner of the common Miſſeltoe: between every pair of leaves ſhoot forth two ſlender ſtalks of about three inches in length, with pairs of oblong purple berries ſet oppoſite to each other. It is a native of America and the Weſt Indian iſlands, and is ſaid to grow principally on the Mancineel tree [b].

4. This ſeems by its way of growth to be near of kin to the Opuntiæ, having no leaves or rather ſtems; but what we may call the ſtem or firſt leaf at the coming out of the trunk of the tree is flat, ſomewhat roundiſh, of a very dark-green colour, having at every inch and half's diſtance, out of their ſides only, oppoſite branches, growing out of one another, after the manner of the Indian Fig, being an inch and half long, and an eighth of an inch broad, the whole growing to a foot in length: at the ends of the branches are ſmall yellowiſh flowers, two together: berries whitiſh, like thoſe of the ordinary Miſſeltoe. Native of Jamaica, on trees [c]. Alſo of the Society Iſles.

5. Branches dichotomous: joints three-cornered, oblong, compreſſed, very ſhort, gradually ſmaller, wrinkled [d]. Native of Japan. Taken at firſt by Thunberg for the preceding ſpecies [e].

6. This is a very branching, brachiate, jointed ſhrub, with the bark ſomewhat wrinkled longitudinally; each joint being round, and ending at top in a bluntiſh ſcale, exactly as in Salicornia herbacea, to which it approaches very much in ſtature. It has no leaves like the two preceding. Anthers ſeſſile two or four. Berries lateral, oppoſite, often three together, ſeſſile, the ſize of a currant, with a very ſhort cylindrical ſtyle, and an obtuſe ſtigma, about which is a little area girt with a four-cornered, ſhort, ſcarcely four-cleft margin. Native of the Cape of Good Hope, on trees; found by Sparrmann [f].

7. This hangs down from trees after the manner of Miſſeltoe, having a roundiſh, green, woody, ſtriated ſtalk, as big as a gooſe quill, two or three feet long, ſometimes flatter and ſometimes rounder, having a large pith. It divides into ſeveral branches, and theſe into twigs, at the diſtance of one, two or three inches; at which diviſions the ſtalk is always ſet round, almoſt after the manner of ſtellated plants, with roundiſh green leaves, an inch and half long, juſt like ſtalks, only ſmaller and very numerous, ſo that it appears very buſhy. Native of Jamaica, in the North parts [g].

Browne ſays it is pretty frequent in that iſland; growing on all the larger trees in every ſavannah. It is uſed there for the ſame purpoſes, as the Miſſeltoe of the Oak in England, but Dr. Browne never knew it to have any remarkable effect.

8. A ſhrubby ſpecies, according to Plumier's figure, with ſimple branches, ovate, ſinuous, very broad leaves, which are oppoſite and footſtalked: racemes ſeveral, upright, ſimple, axillary, upright and ſubumbellate: berries verticillate, placed at intervals, roundiſh and umbilicate: their colour is ſaid to be purple. Native of the Weſt Indies and Guiana [h].

9. Paraſitical, hoary but not tomentoſe. Found at the Cape of Good Hope by Thunberg [i].

10. Stem herbaceous, a foot high, even, brachiate, four-cornered. Leaves petioled, even, quite entire, veinleſs: the lower one ſmaller. Spikes axillary, ſeſſile, fleſhy, oblong. Linneus ſaw only female flowers, and no fruit: the genus therefore is uncertain; and it may be a ſpecies of Loranthus. Native of Philadelphia, in moiſt meadows. Found by Kalm [k].

11. Paraſitical. Native of the Cape of Good Hope, where it was found by Thunberg [l].

12. Native of New Zealand [m].]

PROPAGATION AND CULTURE.

1. Miſſeltoe is always produced from ſeed, and cannot be cultivated in the earth like moſt other plants, but will always grow upon trees: hence the ancients thought it was an excreſcence of the tree, without any ſeed being previouſly lodged there; which opinion has been confuted from repeated experiments.

The manner of its propagation is this. The Miſſeltoe Thruſh, which feeds upon the berries of this plant in winter, when they are ripe, often carries them from tree to tree; for the viſcous part of the berry, which immediately ſurrounds the ſeed, ſometimes faſtens it to the outer part of the bird's beak, and to diſengage it, he ſtrikes his beak againſt the branch of the tree on which he alights, and leaves the ſeed ſticking to the bark; if this ſhould chance to be a ſmooth part, the ſeed will adhere to it, and the following year will put out and grow. In the ſame manner it may be propagated by art. The trees on which it moſt readily takes are the Apple, Aſh, White-thorn, and others which have a ſmooth rind. I have ſeveral times tried it upon the Oak without ſucceſs, for the bark of that tree is of too cloſe a texture to admit the ſticking of the ſeeds thereto, which is alſo the reaſon why it is ſo rarely found upon the Oak. Notwithſtanding the great encomiums which have been given to the Miſſeltoe of the Oak for its medicinal virtues, I cannot help thinking that it is equally good from whatever tree it be taken: nor is it poſſible to find this plant growing in any quantity upon the Oak; ſo that they who pretend to furniſh it for medicinal uſe, do but impoſe upon their cuſtomers; for it is ſo rarely met with, that whenever a branch of an Oak-tree has Miſſeltoe growing upon it, it is cut off and preſerved by the curious in their collections of natural curioſities, and of theſe there are few to be ſeen in England.

As to what ſome perſons have aſſerted, of its being propagated by Miſſeltoe Thruſhes, who having eat the berries, void the ſeed in their dung upon the branches of trees, I can by no means agree to it; for in this caſe the plant would always be found on the upper part or the ſides of ſuch branches, upon which only the dung can be ſuppoſed to lodge; whereas it is generally found at the under ſide of the branches: beſides I believe that the ſtomachs of theſe birds are too powerful digeſters, to ſuffer any ſeeds to paſs ſo entire as to grow.

[The firſt of theſe objections would apply to the other mode of propagation by nature and art. The ſecond is generally right, but yet it is certain that ſeeds now and then eſcape the powers of digeſtion, probably by a paſſage more accelerated than common, and vegetate when they happen to fall on their proper nidus. And though the ſeeds are firſt depoſited upon the upper part of the branch, the rains may ſoon waſh them to the ſides or even the lower part.

The ancients, as Ariſtotle, Pliny, &c. inſiſted that the only mode of propagation of the Miſſeltoe is by the excrement of birds, ſuppoſing that the heat of the body is neceſſary to mature the ſeed for vegetation. Julius Scaliger, John Bauhin, and other moderns of the old ſchool, adopted the idea of equivocal generation. Ray was too good a philoſopher to admit this doctrine, and aſks very reaſonably, to what end ſo great a quantity of ſeed ſeemingly perfect was created, if it were all barren and unfruitful? But Ray lived to ſee his theory and that of Ariſtotle confirmed by experiment; for Mr. Doody, an Apothecary of London, inſerted a ſeed of the Miſſeltoe into the bark of a White Poplar tree, which grew in his garden, with complete ſucceſs; this has been done ſince by many perſons, both by rubbing the berries on the ſmooth bark of various trees, and by inſerting them in a cleft. Doody ſeems to have bored a hole for the reception of the ſeed.

It is wonderful, as Ray juſtly obſerves, that Botaniſts and Philoſophers ſhould chooſe to argue pro and con ſo many years, not to ſay centuries, rather than take the pains to conſult nature, and determine the matter by an eaſy experiment [n].

The celebrated Tournefort, in his travels in the Levant ſaw numbers of wild Pear trees covered with Miſſeltoe, and obſerved upon their trunks, how hard ſoever the bark was, the germination of the ſeeds. Theſe ſeeds, ſays he, which are in the ſhape of a heart, were

out of their caſes, and had faſtened themſelves by their glue to the trunks and branches of theſe trees, at the time that winds or ſome other cauſe made them fall off. Each ſeed lay upon its ſide, in ſuch a manner that the radicle began to pierce the bark, whilſt the eye (or plume) ſhot out and unfolded itſelf°.

DESCRIPTION, *&c.*

This is a ſmall ſhrub, with a round, ſomewhat warted ſtem. Leaves alternate, erect, on ſhort petioles, elliptic, very ſmooth, veined, ſerrate, the conſiſtence of the Bay. Peduncles axillary, ſolitary, nodding, ſcarcely longer than the petiole, naked, one-flowered. Flowers ſmall. Corolla yellow. When the flower is impregnated, the peduncle is erected, the calyx cloſed and thickened, and its three outer leaflets become brown and hairy. Native of the Canary iſlands, in mountain woods. Found by Francis Maſſon[P].]

DESCRIPTIONS, *&c.*

1. This is a tree, in appearance and colour like V. Agnus castus, except in the leaves, which are nearly roundish, and two inches long. Peduncles axillary, short, one-flowered [a].

Stem creeping. Leaves decussated, petioled, ovate, obtuse, quite entire, green above but underneath soft and white-tomentose. Flowers at the top of the branchlets, at first axillary, but finally terminating and panicled. Panicle subtrichotomous, very shortly peduncled. Berry globular, twin, four-valved, four-celled. Seeds minute. Native of China and Japan [b].

2. Branches below roundish, smooth, purplish, above four-cornered with a rust-coloured down, jointed: joints two inches long. Gems golden-rust-colour. Leaflets on very short petioles from two to five inches in length, the lateral ones a little smaller, elliptic-lanceolate, wider outwards, towards the base gradually narrowed a little, bluntly acuminate, veined, smooth on both sides, quite entire. Petioles purplish, above channelled, an inch and half long, golden tomentose at the top. Axillary peduncles, opposite, solitary; the terminating ones in pairs, length of the petioles, compressed. Pedicels in threes, one-flowered, half an inch long, the middle one shorter. Bractes two, bristle-shaped, towards the top and at the base of the lateral pedicels. Calyx almost an inch long; corolla twice the length, golden-tomentose on the outside. Calyx a little different from its congeners; but the corolla the same. Native of Cayenne [c].

3. Branches obscurely four-cornered, smooth, with an ash-coloured bark. Leaves at the tops of the branches, opposite, petioled: leaflets petioled, membranaceous; the lateral ones oblong, scarcely an inch long, acute, sometimes acuminate; the end one four or five inches long, ovate, acuminate. Peduncles axillary, solitary, three or four times dichotomized: pedicel at the divisions one-flowered, filiform, like the rest. Frequent in the islands of Martinico, St. Lucia, and Santa Cruz. Called by the French there, bois de Lezard.

4. Branches four-cornered, pubescent. Leaves opposite, petioled: leaflets sessile, two inches long, or a little less, ovate attenuated, quite entire, above marked with very fine lines along the nerves, and smoothish; beneath ribbed, veined, pubescent. Panicle terminating, large, trichotomous, finally dichotomous. Under the first divisions on each side is a ternate leaf. Bractes spreading, opposite, sessile, oblong, obtuse, length of the calyx, hoary. Flowers six or seven on the outmost branches of the panicle, sessile, alternate. Calyx bell-shaped, five-toothed, hoary. Corolla twice as long as the calyx, tomentose on the outside. Berry the size of black Pepper, four-seeded. Native of the East Indies.

It differs from V. trifolia, in having the leaves not hoary beneath, the pedicels not dichotomous, but with the flowers longitudinally sessile and alternate; and by the squarrose habit of the panicle, from the spreading and reflex bractes, which are bigger than in the other species [d].

5. Leaflets ovate, acuminate at both ends, smooth above, pubescent underneath. Found in the vast woods of Ceylon by Koenig [e].]

6. This has a shrubby stalk eight or ten feet high, sending out their whole length opposite branches, which are angular, pliable, and have a grayish bark. Leaves for the most part opposite upon pretty long foot-stalks; they are composed of five, six or seven leaflets spreading out like the fingers of a hand; the lower ones small; and the middle largest; they are smooth and entire; the largest are about three inches long, and half an inch broad in the middle, ending in blunt points, of a dark green on their upper side, but hoary on their under. The flowers are produced in spikes at the extremity of the branches, from seven to fifteen inches in length, composed of distant whorls; in some plants they are white, in others blue. They are generally late before they appear, so that in bad seasons they do not open fair in England, and even in warm years the plants produce no seeds here. They have an agreeable odour when they open fair, and make a good appearance in autumn, when the flowers of most other shrubs are gone; for in warm mild seasons I have seen these shrubs in full flower the middle of october.

[The fruit, according to Gærtner, is a berried drupe, received into the calyx, globular, with a little point upon the top, rufescent, the size of a large pepper corn: pulp thin, somewhat aromatic: shell bony, ovate-globular, acuminate downwards, four-celled. One seed in each cell, fastened to the base of it, oblong, acuminate at bottom, angular rufescent. We shall seek in vain for a four-seeded berry in the Vitex. Gærtner remarks that he never could see a six-cleft corolla, except in Tournefort's figure, whence Linneus took his generic character. Native of Sicily and the kingdom of Naples, where Ray observed it to be plentiful, flowering in august. Scopoli found it about Tergeste and in Istria—Allione on the maritime hills near Albenga—Bellardi between Menton and Monaco—Dr. Smith near Lodano, on Dec. 26, in seed. He remarks that it is a small shrub there, and that the seeds have an unpleasant aromatic smell [f]. Forskahl found it in Egypt—Desfontaines, in the kingdom of Tunis—Rauwolff, about Aleppo and Racka—Gronovius in Virginia. It was cultivated here in 1570, according to Lobel [g].

The seeds, from the time of Dioscorides and Pliny, have been highly celebrated for securing chastity, hence the absurd officinal name of the shrub, Agnus castus; *αγνος* in greek being the same with *castus* in Latin: and hence the Athenian matrons, in the sacred rites of Ceres, used to strew their couches with the leaves. Hence also it has had the affected name of Piper eunuchorum and monachorum.

The seeds of the Chaste-tree are, however, so far from being thought antiaphrodisiac, that writers of later times have ascribed to them an opposite quality; their aromatic pungency seems to favour this opinion, and Bergius states them to be carminative and emmenagogue [h]. See n. 9. and 13.

β. Mr. Miller considers the Broad-leaved Chaste-tree as a distinct species. He says] it is a lower shrub, seldom rising more than four or five feet high, with several stalks which do not branch so much as the other; their bark is also whiter. The leaflets are not so disproportionate in their length, the longest being seldom more than three inches, and the shortest an inch and half: they are near an inch broad, serrate, and not so stiff as those of the former. The spikes are shorter; the flowers smaller, always blue, and appear sooner. Native of the South of France and Italy.

7. [Stature of the preceding, but smaller in all its parts, with quinate acuminate pinnatifid leaves pubescent underneath. Vitex Negundo, under which name this species occurs in the gardens, is quite another

[a] Linn. suppl. [b] Thunberg. [c] Vahl.

[g] Adv. 423. Hort. kew. [h] Woodville.

Digitized by Google

plant, differing in the ſize of all the parts, and the raceme-panicled, not whorled inflorescence [t].]

Mr. Miller deſcribes it as a lower ſhrub, ſeldom riſing more than three feet high, ſending out on every ſide ſpreading branches, which are ſlender and angular. Leaves oppoſite upon pretty long footſtalks; ſome compoſed of three, others of five leaflets, which are deeply and regularly cut on their ſides like pinnatifid leaves, and end in acute points: the largeſt of theſe leaflets is about an inch and half long, and three quarters of an inch broad in the middle; they are of a dull green colour on their upper ſide and gray on their under. The branches are terminated by ſpikes of flowers three or four inches long, diſpoſed in whorls; in ſome plants they are white, in others blue, and ſome have bright red flowers: they are in beauty from the middle of july to the beginning of ſeptember; but no ſeeds are produced in Europe. Native of China: whence ſeeds were ſent to Paris by the Miſſionaries. Mr. Miller had young plants from France: [but the ſpecies ſeems to have been ſince loſt in England, as it does not appear in the Kew catalogue.

8. This very much reſembles Vitex trifolia, but differs in having the leaves very ſmooth on both ſides, and a dichotomous panicle from the firſt diviſion. Found by Koenig in the vaſt woods of Ceylon [k].

9. Leaflets ovate, acute, quite entire, tomentoſe underneath [l]: the two neareſt to the petiole ſmaller [m].

Stem ſhrubby, branched, round, eight feet high, the thickneſs of a finger, procumbent, ſometimes creeping. Leaves ternate, ſeldom quinate; leaflets waved, duſky green above, cinereous-hoary beneath, ſoft: common petioles long, oppoſite. Flowers violet in dichotomous terminating racemes. Upper lip of the corolla trifid, lower bifid. Fruit ſmall, globular, hard, ſmooth, black, like Pepper, four-ſeeded [n].]

Mr. Miller ſays, that it riſes nine or ten feet high, with many ſide branches, which have a brown bark; and that the flowers are ſmall and white, not followed by ſeeds in England. [Native of the Eaſt Indies; very common on the coaſt both of China and Cochinchina, creeping in the ſand; alſo in the Friendly iſlands.

The fruit is reputed in the eaſtern countries to be warm, diſcutient, nervine, cephalic, and emmenagogue; and to be of ſervice in paralyſis, weakneſs and pains of the limbs. It is in great uſe among Indian practitioners both internally and externally. The plant has a bitter taſte, and a ſtrong ſomewhat aromatic ſmell [o].

10. Native of Jamaica, in ſhady places.

11. This is a middle-ſized tree. Branches roundiſh, warted, at the warts a little dilated and four-cornered, ſmooth with an aſh-coloured bark, even: branchlets leafing and flowering, the lower alternate, the end ones often in threes, alternately compreſſed. Leaves at the ends of the branchlets, oppoſite, approximating, ſpreading: leaflets tender, the middle ones petioled, the outmoſt ſeſſile, four inches long, the outer ones gradually leſs, all lanceolate, attenuated, ſharp at each end, veined, very ſmooth, on petioles two or three inches in length. Peduncles axillary, ſolitary, length of the petiole, ſmooth, ſlender. Flowers ſix to twelve at the top of the peduncles at firſt ſeſſile, but afterwards very ſhortly pedicelled. At the baſe of the calyx are a few minute bractes. Calyx ſilky-villoſe, five-toothed; when fruiting enlarged to five times its former dimenſions, hemiſpherical, ſmooth, netted-veined. Corolla alſo ſilky-villoſe; upper lip bifid, lower trifid: throat villoſe. Drupe ovate-oblong, ſubmucronate, double the ſize of a pea; with a four-celled ſhell in it, having one ſeed in each ſhell. Native of the iſland of Trinidad, where it was found by Ryan [p].

12. Leaflets three or five, ovate-lanceolate, ſinuate-ſerrate, underneath naked and veined [q].

Stem arboreous, twiſted, the thickneſs of the human arm, with ſpreading branches. Leaflets lanceolate, for the moſt part quite entire, but ſometimes ſerrate, flat, veined, of a duſky aſh colour, on oppoſite petioles. Flowers purpliſh, in looſe, terminating, erect racemes. Calyx, corolla and fruit as in V. trifolia. The taſte

[t] Willdenow. [k] Linn. ſuppl. [l] Linn. ſpec. [m] Linn. ſuppl. [n] Loureiro. [o] Idem. [p] Vahl. [q] Linn. ſpec.

and ſmell as in that. The qualities alſo the ſame, only weaker [r].]

Stalks eight or ten feet high, with a gray bark. Branches oppoſite. Leaves oppoſite, upon long footſtalks: leaflets deeply ſerrate, ending in very acute points; the largeſt three inches and a half long, and an inch and quarter broad, dark green above, but gray beneath. Flowers in oppoſite axillary whorled ſpikes: and the branches are terminated by branching ſpikes of flowers, which are blue. They appear in july and auguſt, but do not produce ſeeds in England.

[Native of the Eaſt Indies, China, and Cochinchina. —Cultivated in 1697, by the Dutcheſs of Beaufort [s].

13. Stem ſhrubby, erect, eight feet high, thick. Leaves quinate, rarely ternate, lanceolate, crenate, ſome quite entire, bright green, tomentoſe, wrinkled, ſtrong-ſmelling, oppoſite, on long petioles. Flowers pale violet, on long linear ſpikes, often heaped, terminating: involucrets awl-ſhaped, many-flowered. Calyx very ſmall, five-cleft, acute, permanent. Corolla tube ſhort, globular: border ſpreading, five-cleft; ſegments obtuſe, the four upper nearly equal, the loweſt bigger. Filaments ſhorter than this ſegment, but longer than the others. Fruit roundiſh, brown, ſmaller than Pepper, containing four ſeeds. Native of China and Cochinchina. Qualities the ſame as the trifolia: the leaves are moſt frequently uſed externally, in paralyſis, contraction and weakneſs of the limbs, and wandering pains [t].

14. Native of Ceylon and other iſlands of the Eaſt Indies. Doubtful whether it appertains to this genus. Loureiro determines that it not only is not of this genus, but that it belongs to another claſs and order, pentandria digynia. He thus deſcribes it under the name of Aglaia odorata. It is a tree eight feet in height; the wood hard and yellowiſh; the bark thin and brown; the branches ſpreading; the head very cloſe and thick. Leaves ternate or quinate; leaflets oval, attenuated at the baſe, quite entire, ſmooth, ſhining; on ſhort petioles. Flowers yellow, very ſmall, globular, ſweet-ſmelling, on oblong, axillary racemes. Fruit ſmall, red. Native of China and Cochinchina, where it is alſo cultivated in the gardens of the great, for its beauty and ſweetneſs. In Malay it is called Tſjiulang. Loureiro has named it from the ſplendour and beauty of the plant, and from the ſweetneſs of the flowers. He ſuſpects the Bumalda trifolia of Thunberg to be of this genus; but Willdenow remarks, that Bumalda differs in many points from Loureiro's generic deſcription of Aglaia.]

PROPAGATION AND CULTURE.

6. This plant is very hardy, and may be propagated by planting the cuttings early in the ſpring, before they ſhoot; it requires a freſh light ſoil, and muſt be frequently refreſhed with water until it has taken root; after which the plants muſt be carefully cleared from weeds during the ſummer ſeaſon, and if the following winter prove ſevere, lay a little mulch upon the ſurface of the ground between the plants, to prevent the froſt from penetrating to their roots, which would injure them while they are young; and as theſe cuttings are apt to ſhoot late in the year, their tops will be very tender, and the early froſts in autumn often cut them down a conſiderable length, if they are not protected, therefore they ſhould then be covered with mats, which will be of great ſervice to them. Toward the middle of March, if the ſeaſon is favourable, you ſhould tranſplant them either into the places where they are deſigned to remain, or into a nurſery to grow two or three years to get ſtrength, where they muſt be pruned up, in order to form them into regular ſtalks, otherwiſe they are very ſubject to ſhoot out their branches in a ſtraggling manner.

They may alſo be propagated by laying down their branches in the ſpring of the year, in doing which be very careful not to break them, for their ſhoots are apt to ſplit if they are violently forced; theſe will take root in one year, provided they are watered in very dry weather, and may then be tranſplanted out, and managed as was directed for thoſe plants raiſed from cuttings.

[r] Loureiro. [s] Hort. kew. [t] Loureiro.

The

Digitized by Google

The 9th ſort being too tender to live in the open air in England, muſt be planted in pots, and conſtantly kept in the ſtove; it is propagated both by cuttings and layers, but the cuttings of this muſt be planted in pots, and plunged into a moderate hot-bed, covering them cloſe with a bell or hand-glaſs to exclude the air; they ſhould be refreſhed with water now and then, but it muſt not be given them too freely. The beſt time to plant the cuttings is about the middle or latter end of april, for if they ſucceed, they will put out roots in ſix or ſeven weeks, and will then begin to ſhoot, they ſhould therefore have the free air gradually admitted to them to prevent their ſhooting weak; then they may be carefully taken up, and each planted into a ſeparate ſmall pot filled with light earth, and plunged into the hot-bed again, ſhading them from the ſun till they have taken new root; after which they ſhould have plenty of free air at all times when the weather is good, treating them in the ſame manner as other tender plants. In winter they muſt be kept in a moderate temperature of heat, but in the ſummer they ſhould have the free air in mild weather, but muſt not be removed into the open air.

As this plant retains its leaves all the year, it makes a variety in the ſtove, but the flowers have no great beauty.

7. Plant cuttings in the ſpring in pots, plunging them into a moderate hot-bed and covering them with glaſſes. When theſe are well rooted, take them carefully up, and plant each in a ſeparate ſmall pot filled with light earth, placing them in the ſhade until they have taken new root: then remove them to a ſheltered ſituation with other greenhouſe plants, where they may remain all the ſummer. In autumn they muſt be put under ſhelter; but as they caſt their leaves early in autumn, they muſt not be much watered in winter. They are late in putting out new leaves in the ſpring, and have much the appearance of dead plants before theſe appear.

12. This alſo is encreaſed by cuttings in the ſpring, a little before the buds open, and muſt be managed as directed for the ſeventh ſpecies. Having lived ſome years in the open air, the ſevere froſt of 1740 deſtroyed all the plants. [But it has been ſince recovered to our gardens.

The directions given for the ſeventh and ninth ſpecies will ſuffice for all the reſt, which are natives of the Eaſt or Weſt Indies, China or Japan.

DESCRIPTIONS, *&c.*

The common Vine is univerſally known to have a thick twiſted irregular weak ſtem, covered with a brown

Digitized by Google

brown cloven bark, and having very long tough flexible branches, trailing along the ground, or climbing trees by means of tendrils. The leaves are lobed and ſinuated, ſerrate, ſmooth and alternate, on long foot-ſtalks. The tendrils are oppoſite to a leaf and are attended by the flowers in a raceme. The flowers are whitiſh or herbaceous, very ſmall and inſignificant in appearance but having a very agreeable ſmell; the petals cohering at the tip and concealing the genitals in manner of a veil, but ſoon fall off. Berry globular, in ſome varieties ovate, before it is ripe regularly divided into five cells; but afterwards one-celled, almoſt pellucid, coloured in ſome, colourleſs in others. In the middle is a ſhort column, ſpringing from the woody fibres of the pedicel of the berry; to the top of this the ſeeds are faſtened by its peculiar umbilical chord: this chord is filiform, running along the inner ſide of the ſeed to its very top, then reflected to the back, and finally entering the navel. Seeds naturally five, but for the moſt part fewer [u]: others have not diſcovered more than two. In ſome berries they are all abortive.

Native of moſt of the temperate parts of the world. In very cold regions it refuſes to grow; and within 25° or even 30° of the equinoctial line, it ſeldoms flouriſhes ſo as to produce good fruit. In the Northern Hemiſphere, the proper wine country is from 25° to 51° of latitude. Thunberg informs us, that grapes do not ripen very well in Japan, and are not high flavoured in that country. Browne however ſays that the Muſcadine Grape ripens well in Jamaica, and would produce a mellow and rich wine, if care were taken to cultivate it. The Vine is ſpontaneous in Carolina and all North America, from 25° to 45° of latitude, but they do not ſucceed in making wines there in the ſame latitude with Spain and Italy. The American woods are in many parts ſo entangled with vines for many miles together, that their trailing branches are a great impediment in travelling, and lofty trees are overtopped and wholly covered with them [x].

The Vine was gradually introduced into the different countries of ſouthern Europe, from the Eaſt, where we know it was cultivated from the time of Noah. In the age of Homer it grew wild in the iſland of Sicily, and probably in the adjacent continent, but it was not improved by ſkill, nor did the rude inhabitants extract a liquor from it. A thouſand years afterwards, Italy could boaſt, that of the fourſcore moſt generous and celebrated wines, more than two thirds were produced from her own ſoil. The bleſſing was ſoon communicated to the Narbonneſe province of Gaul; but ſo intenſe was the cold to the north of the Cevennes, that in the time of Strabo, it was thought impoſſible to ripen Grapes in thoſe parts of Gaul. This difficulty, however, was gradually vanquiſhed; and there is ſome reaſon to believe, that the vineyards of Burgundy are as old as the age of the Antonines. In the beginning of the fourth century, the orator Eumenius ſpeaks of the vines in the territory of Autun, which were decayed through age, and the firſt plantation of which was totally unknown. The Pagus Arebrignus is ſuppoſed, by M. D'Anville, to be the diſtrict of Beaune, celebrated even at preſent for one of the firſt growths of Burgundy [y].

Mr. Miller tells us, that the vineyards in ſome parts of Italy will hold good above three hundred years, and that vines of one hundred years old are accounted young ones.

It would ſeem probable that the luxurious Romans ſhould introduce the Vine into Britain, during their eſtabliſhment in the iſland; and that it ſhould have maintained its ground ever ſince, with various fortune. But there is little doubt that Vineyards were common appendages to Abbies and Monaſteries, which were frequently filled with Monks who were foreigners, or had lived much in Italy, and had there contracted ſuch a habit of drinking wine with their meals, that it appeared to be in a manner a neceſſary.

Mr. Pegge, from Pliny's ſilence on that head, in the large account which he gives of the Vine in his fourteenth book, concludes that Britain had it not when Pliny wrote. But Tacitus, writing of the times when Julius Agricola commanded here, expreſsly denies us the Vine. If ſo, it is not probable that we had it for many years after, ſince Domitian ordered vineyards in the Provinces to be deſtroyed, both becauſe they occaſioned a ſcarcity of corn, and were an incitement to ſedition by the encouragement which they gave to drunkenneſs: and from this time none could plant vineyards without the permiſſion of the Emperors; till Probus, who acceded in A.D. 276, reſcinded the edict, towards the end of his reign. Mr. Pegge conceives that licence was granted the Provincials to plant vineyards about the year 280, and the Britanni are expreſsly mentioned by Vopiſcus among the nations who partook of it.

Bede, who finiſhed his hiſtory A.D. 731, writes expreſsly, "Vineas etiam quibuſdam in locis germinant."

It is natural to ſuppoſe, that the propagation of the Vine would be firſt attempted in the ſouthern parts of our iſland, both becauſe they are the warmeſt, and the neareſt to Gaul. Accordingly the neighbourhood of Wincheſter was formerly famous for Vines, as appears from the old verſes cited by Mr. Somner; and Twyne ſuppoſes this city to have taken its name from hence.

Of Canterbury and that neighbourhood the ſame author makes the abbat of St. Auguſtine's ſay, that their houſe was formerly not deſtitute of vines: and Somner informs us, that in the year 1285, both that abbey and the priory of Canterbury were plentifully furniſhed with vineyards.

At Rocheſter, a large piece of ground adjoining to the city is now called the Vine: another is ſo called at Sevenoke in Kent: this alſo was the name of the ſeat of the barons Sandes in Hampſhire. At Halling, near Rocheſter, the biſhop of that ſee had formerly a vineyard; for when Edward II. in the nineteenth year of his reign, was at Bockinfeld, biſhop Hamſon ſent him thither, as Lambarde tells us, "a preſent of his drinkes, "and withal both wine and grapes of his own growth "in his vineyarde at Halling." Captain Nicholas Toke, of Godington, in Great Chart, in Kent, "hath "ſo induſtriouſly and elegantly, ſays Philipot, cultivat-"ed and improved our Engliſh Vines, that the wine, "preſſed and extracted out of their grapes, ſeems not "only to parallel, but almoſt to out-rival that of "France."

Of Suſſex, Lambarde writes, "Hiſtory doth mention, "that there was about that time, (the Norman inva-"ſion) great ſtore of Vines at Santlac (near to Bat-"tel.") He adds, as to Berkſhire, "the like where-"of I have redd to have been at Wyndſore, in ſo "moche as tythe of theim hathe beene theare yelded "in great plenty, which gyveth me to think, that "wyne hath been made longe ſence within the realme; "although in our memorie it be accompted a great "deintye to heare of." He farther obſerves, that ſome part of the wine was ſpent in the king's houſhold, and ſome ſold for the king's profit.

John Twyne has remarked, that William of Malmeſbury has extolled the Vines and wine of Glouceſterſhire; and the paſſage is extant in William's book de Geſtis Pont. IV. p. 283. See alſo Camden [z].

Domeſday book mentions at Rageneia in Eſſex one park, and ſix arpennies of vineyard, which, if it takes well, yields twenty modii of wine.—And at Ware, a park and ſix arpennies of vineyard very lately planted.

We hear of vineyards alſo in Middleſex, Cambridgeſhire at Denny abbey, the Iſle of Ely, at Dunſtable, and at St. Edmundſbury; in the engraved plan of which town the vineyard of the abbey is particularly noted. Within the walls of the city of London there is a ſtreet called the vineyard; and in the liberties and ſuburbs, and in Weſtminſter, there is Vine-ſtreet in Hatton garden, and St. Giles's and Piccadilly; and the vineyards by Houndſditch and Coldbath fields [a].

In the archives of the church of Ely is the following regiſter:

10 buſhels of Grapes from the Vineyard	0	7	6
7 Dolia Muſti from the Vineyard 12 Edw. II.	15	1	0
Wine ſold for	1	12	0
Verjuice	1	7	0
One Dolium, and one pipe filled with new wine, and ſuppoſed at Ely.			
For wine out of this Vineyard	1	2	2
For verjuice from thence	0	16	0
No wine, but verjuice made 9 Edw. IV.			

Hence it appears plainly that at Ely Grapes would ſometimes ripen, and the convent made wine of them; and when they did not, they converted them into verjuice [c].

In Northamptonſhire, Martin, Abbot of Peterborough, in the time of King Stephen, is ſaid expreſsly, in the Saxon Chronicle, to have planted a vineyard, and it was a large one [d]. Madox, in his Hiſtory of the Exchequer writes, that the Sheriffs of Northamptonſhire and Leiceſterſhire were allowed in their account, for the livery of the King's vine-dreſſer at Rockingham, and for neceſſaries for the vineyard [e].

There are evidences of Vineyards ſtill farther north, as at Darley abbey in the county of Derby. And perhaps the ſeveral villages there of South Winfield, North Winfield, and Wingerworth, take their names from vineyards formerly flouriſhing at thoſe places [f].

Petrarch therefore muſt ſurely have been ill informed, when he ſays that "the Engliſh drink nothing but beer and cyder, and the Flemiſh hydromel; each of theſe countries being ſo far diſtant from thoſe in which Vines grow, that the people cannot afford to purchaſe wine [g]." This famous poet lived in the reigns of our three firſt Edwards, being born in 1304 and dying in 1374. Now long before this, in different years of Henry the ſecond's reign, allowances were made to the officer who farmed Windſor of that prince for wine, perry and cyder. In the reign of Henry III. the neglect of vineyards in England, is attributed by Twyne in part to that fondneſs for French wine which then came upon us. In this king's time, about the year 1260, a Dolium (thirty-ſix gallons) of the beſt wine could be bought for forty ſhillings, ſometimes for two marks, and ſometimes for twenty ſhillings. In 1285 (temp. Edw. I.) we have ſeen, that the churches at Canterbury were plentifully furniſhed with vineyards. In 1325, the 19th of Edw. II. we have alſo ſeen that the biſhop of Rocheſter ſent the King wine and grapes of his own growth from his vineyard at Halling in Kent [h]. As to the ſplendid reign of Edward III. when our commerce ſo much increaſed, and we had the command of ſo great part of France, it cannot be ſuppoſed that there was any want of French wines in England, allowing that our own vineyards were much neglected. If Petrarch meant only that wine was not the general drink of the commonalty in England, it never has been ſo at any period, nor is it ſo even in this luxurious and expenſive age.

Several cauſes may be aſſigned why vineyards were neglected, and at length in a manner diſuſed in this country. The principal cauſe probably was that our wine was of an inferior quality, and that better wine could be had cheap from our French provinces. The advancement of agriculture alſo contributed to their being relinquiſhed. We may however fairly conclude with Mr. Pegge, that there were many vineyards in England, for ſeveral centuries ſince the conqueſt; few of our greater religious foundations, in the ſouth at leaſt, having been without them.

In more modern times, the Vine, ſays Dr Plot, has been improved by Sir Henry Lyttleton to that advantage at Over-Arley, that he has made wine ſo good there, as not to be diſtinguiſhed from the beſt French wines. And Dr. Ralph Bathurſt, preſident of Trinity college and dean of Wells, made as good claret at Oxford in 1685, as one could wiſh to drink [i].

Barnabe Googe, in his Epiſtle to the Reader, prefixed to his tranſlation of Hereſbachius's Huſbandry, 1586, ſays, "he is fully perſuaded we might have a reaſonable good wine growing in many places of this realme: as undoubtedly we had immediately after the Conqueſt, till partly by ſlothfulneſs, not liking any thing long that is painful, partly by civil diſcord long continuing, it was left, and ſo with time loſt, as appeareth by a number of places in this realme, that keep ſtill the name of Vineyards: and upon many cliffs and hills are yet to be ſeen the roots and old remains of Vines. There is beſides Nottingham an ancient houſe called Chilwell, in which remaineth yet as an ancient monument in a great window of glaſs, the whole order of planting, proyning, ſtamping and preſſing of Vines. Beſide, there is yet alſo growing an old Vine that yields a Grape ſufficient to make a right good wine, as was lately proved by a gentlewoman in the ſaid houſe. There hath moreover good experience of late years been made by two [illegible] and honourable Barons of this realme, the Lord [illegible]am, and the Lord Williams of Tame, who both had growing about their houſes as good Vines as are in many places of France."

Samuel Hartlib, in 1659, ſays, that here in England ſome ingenious gentlemen uſually make wine, very good and long laſting. He inſtances Sir Peter Ricard, at Great Chart, in the Wilde of Kent, a place very moiſt and cold, who yearly made ſix or eight hogſheads, which was very much commended by divers who had taſted it.

We are informed in Rea's Flora (1702) that Sir Thomas Hanmer aſſerted, he had drunk in ſeveral places good wine of Engliſh growth.

At Arundel caſtle in Suſſex, a ſeat of the Duke of Norfolk's, a noble Vineyard was ſome years ago planted: it has ſucceeded, and annually yields conſiderable quantities of wine: there are at this time (1763) in his grace's cellar at Arundel, above ſixty pipes of excellent Burgundy. This wine is not, it is true, of quite ſo fine a flavour as the wines of Beaune; yet does it much exceed quantities of Burgundy wine annually imported into England, and moſt of what is conſumed commonly in France [k].

Mr. Bradley ſays, he cannot help mentioning how our poor ſoils might be improved by making of vineyards; a good inſtance of which is at Mr. John Warner's, a gentleman of Rotherhithe, who makes good wine from his own vineyards.

Stephen Switzer, in his Ichnographia Ruſtica, publiſhed in 1742, affirms that Vineyards may be ſo cultivated in England, as to produce large quantities of Grapes, and thoſe ſo well ripened, as to afford a good and ſubſtantial vinous juice: that there were then in ſeveral parts of Somerſetſhire flouriſhing Vineyards, and that the Vineyard of the late Sir William Baſſet annually produced ſome hogſheads of good-bodied and palatable wine.

Bartholomew Rocque, of Walham Green, made wine for thirty years from a Vineyard he had planted in a common field garden; and although the ground was flat, the wine was as good as that of Orleans or Auxerre.

I have known, ſays Mr. Hanbury, good wine made of Grapes growing in England, and have drank our Burgundy no way inferior, as my taſte could find out, to that noted wine which we have conſtantly imported from that country.

Mr. Viſpre, in a diſſertation on the growth of wine in England, printed at Bath in 1786, informs us, that he planted a piece of ground with Vines at Wimbledon in march 1783; that his intention was to train the ſhoots, as he did afterwards at Chelſea, upon the ground in their natural poſitions, like the vines of melons and cucumbers; and that he hoped thus to make good wine with well-ripened Grapes, almoſt every year. In 1784, he preſented his plan to the Society for the Encouragement of Arts, &c. [l]. The ſecond ſeaſon proving more favourable than the firſt, the Grapes on the Vines trained near the ground were conſiderably larger than thoſe of the ſame kind growing on a ſouth wall.

Hales, in his Practical Huſbandry, ſays that he drank

with Dr. Shaw, wines made under his own care, from a little vineyard behind his garden at Kenſington, which equalled many of the lighter wines of France; and while due care was taken of the Vineyard at Hammerſmith, much very good wine was obtained there for ſale: yet neither of theſe were favourable ſpots. Mr. King's Vineyard at Brompton was well known to the curious. As was alſo that of the Hon. Charles Hamilton at Pain's-Hill, near Cobham in Surry. This laſt was ſituated on the ſouth ſide of a gentle hill, the ſoil a gravelly ſand; it was planted entirely with two ſorts of Burgundy Grapes, the Auvernat, which is the moſt delicate, but the tendereſt, and the Miller grape, commonly called the black Cluſter, which is more hardy. The wine which he made reſembled Champagne[m].

From the evidences thus collected I think we may fairly conclude, notwithſtanding the difficulties which the Hon. Daines Barrington and others have thrown in the way; firſt that we have in former times many Vineyards in England, properly ſo called, that were not Orchards of apples and pears, much leſs plantations of currants: and ſecondly, that Vineyards might now be cultivated in the ſouthern and weſtern parts of England, in proper ſoils and ſituations, by perſons ſkilled in their management, provided they adopted the ſorts of Grapes beſt ſuited to the climate, and kept the wines low, as they do in the northern parts of France.]

Mr. Miller, in alluſion probably to ſome of the trials above recited, ſays that if we were to judge only by the ſucceſs of ſome modern eſſays made near London, where ſmall Vineyards have been planted a few years paſt, there would be no great encouragement to begin a work of this kind, becauſe the produce of very few of theſe Vineyards has been ſo kindly as were to be wiſhed: but this ſhould not deter others from making farther trials, for ſcarcely one of them was placed in a proper ſoil and ſituation, and not one was rightly planted and managed: and how can ſucceſs be expected from Vineyards under theſe diſadvantages, when even in France and Italy they would ſucceed little better, if their management were not directed with more judgment. Mr. Miller therefore humbly offers his own opinion, founded on ſome trials he had ſeen made, and on inſtructions that he had received from ſeveral curious perſons abroad who cultivated Vineyards for their own uſe, and from their friends who were very exact in obſerving the ſeveral methods of practice among the vignerons; whence he hopes that the prejudice which moſt people have againſt a project of this kind, will either be removed, or ſuſpended until trials have been judiciouſly made.

[The Vine is not generally reputed to be a tree, but rather a trailing ſhrub; yet in its wild ſtate it arrives ſometimes at a conſiderable ſize. Pliny mentions one which attained a bulk ſufficient to make a ſtatue of Jupiter, and columns for Juno's temple. The great doors of the cathedral of Ravenna were made of Vine-tree planks; ſome of which are twelve feet long, fourteen and fifteen inches broad; the whole ſoil of that country producing vines of prodigious growth. Such another in Margiana is ſpoken of by Strabo, that was twelve feet in circumference. Pliny mentions one of ſix hundred years old in his time. At Ecoan, the late Duke of Montmorency's houſe, is a table of very large dimenſion, made of the like plant. That which renders this the more ſtrange is, that a tree growing in ſuch a wreathed and twiſted manner, rather like a rope than timber, and needing the ſupport of others, ſhould arrive to ſuch a bulk and firm conſiſtence. But ſo it is, and Olearius affirms, that he found many Vines near the Caſpian Sea, whoſe trunks were as big about as a man [n]. No wood, Pliny ſays, is of a more laſting nature. On the Barbary coaſt, Vines are now growing of ſurpriſing dimenſions, ſome of them having trunks eight or nine feet in circumference.

In general we are not to expect Vines that are pruned and dreſſed to attain this enormous ſize; the vigour of the ſtock being transfuſed into the branches, and conſumed in bearing fruit. In our climate in particular we are not to look for inſtances of longevity and magnitude in the Vine. When however it is planted in a genial ſoil and ſituation, it will attain an amazing ſize and expanſion even in this country.

One inſtance we have at Northallerton in Yorkſhire, where a Vine is now (1789) growing, that once covered a ſpace of one hundred and thirty-ſeven ſquare yards; and might probably have covered three or four times that area. The circumference of the trunk, a little above the ground, was three feet eleven inches. It is ſuppoſed to have been planted an hundred and fifty years; but from injudicious management it was then in a very declining ſtate. The ſoil is light and rich, of a dark colour, and inclining to ſand [o].

At Valentines, the ſeat of Donald Cameron, Eſq. to the north of Ilford in Eſſex, is a Vine of the black Hamburgh ſort, which was planted in april 1758. The branches extend two hundred feet, and the ſtem is about nineteen inches in girth. It never produces leſs than three hundred weight of fruit annually, and has been known to bear four hundred weight and a quarter. The average profit, when it was in the hands of a gardener, was eighty pounds per annum; but the Grapes did not then ripen till june: when the hot-houſe was kept warmer they ripened in march; when it is ſuppoſed they would have been worth, in ſome years, three hundred pounds [p].

When Mr. Speechly ſaw it, which was about eight years prior to Mr. Lyſons's account, it was in the hands of the gardener. It then furniſhed the entire roof of a pine-ſtove ſeventy feet long and eighteen feet broad; ſome of the branches alſo were trained downwards, and covered great part of the back wall. It was exceedingly robuſt, and under a very judicious management, by the gardener who planted it. The bunches in general were ſingularly fine, and compoſed of large well-ſwelled berries, but the crop was not large in the year 1788, when Mr. Speechly ſaw it.

Mr. Laurents, head maſter of the grammar ſchool at Bury in Suffolk, gives a detailed account of a Vine there which covers forty-four yards of a wall ten feet high; and ſome of the branches run over the wall and cover about twelve yards more. It is thirty-five or thirty-ſix years old. The cluſters hang very thick, and each weighs from half a pound to a pound. Upon ſome vigorous ſhoots there were about forty cluſters. If it had been always pruned in the manner it has been for three or four years paſt, it would probably have covered three or four times the area of wall that it does at preſent. The ſoil is a light looſe browniſh mould, about two feet thick on a looſe ſand, with coarſe gravel, and at the depth of twenty feet is water [q].

But the moſt famous Vine for the quantity of its produce, is in a grape-houſe on the ſouth ſide of Hampton Court Palace. It is of the black Hamburgh kind, and occupies the whole houſe, which is ſeventy feet by fourteen. It was planted in the year 1769; the ſtem is about thirteen inches in girth; and the principal branch, having been trained back at the extremity of the houſe, is one hundred and fourteen feet in length. This Vine has been known to produce, in one year, two thouſand two hundred bunches of grapes, weighing on an average one pound each [r].

Of Grapes, or the fruit of the Vine, moſt of the uſes are ſo generally known, that it is not neceſſary to enlarge upon them. A few words may ſuffice upon their medical qualities. Of the juice of the unripe fruit is made Verjuice, now much ſuperſeded by juice of lemons; but ſtill employed externally in bruiſes and ſprains. The dried fruit, Uvæ paſſæ majores et minores, Raiſins and Currants, are uſed as agreeable lubricating aceſcent ſweets, in pectoral decoctions, and for obtunding the acrimony of other medicines, and rendering them grateful to the palate and ſtomach. The general effects of wine are, to ſtimulate the ſtomach, exhilarate the ſpirits, warm the habit, quicken the circulation, and promote perſpiration: taken in too large quanti-

ties it is but too well known to prove intoxicating and powerfully ſedative. In many diſorders wine is admitted to be of important ſervice, eſpecially in fevers of the typhous kind, or of a putrid tendency: in many caſes it proves of more immediate advantage than the Peruvian bark. Delirium, the conſequence of exceſſive irritability, and a defective ſtate of nervous energy, is often removed by the free uſe of wine. In the putrid ſore throat, in the ſmall-pox when attended with great debility and ſymptoms of putreſcency, in gangrenes, and even in the plague, wine is conſidered a principal remedy. In almoſt all caſes of languor and great proſtration of ſtrength, wine is a more grateful and efficacious cordial than can be furniſhed from the whole claſs of aromatics.

The Tartar, which is thrown off from wines, and conſiſts of the vegetable alkali ſuperſaturated with acid, is alſo an officinal article. Cryſtals of Tartar are in common uſe as a laxative and mild cathartic; are ſerviceable in the dropſy; and enter ſeveral officinal compoſitions.

Vinegar is eſteemed of great uſe in almoſt all inflammatory and putrid diſorders: and is very efficacious in counteracting the effects of vegetable poiſons. Inhaled in form of a vapour, it is uſeful in the putrid ſore throat. It is alſo much employed as a menſtruum, or for extracting the virtues of other medicines.

The leaves (pampini) and the tendrils (capreoli,) having an aſtringent acid taſte, were formerly uſed in diarrhœas, hemorrhages, and other diſorders, requiring refrigerant and ſtyptic medicines. The juice or ſap of the Vine (lacryma,) has been recommended in calculous diſorders, and is ſaid to be an excellent application to weak eyes, and ſpecks of the cornea*.

Varieties.

The Vine having been aſſiduouſly cultivated from the time of Noah, in a variety of ſoils and climates, the varieties are very numerous, and might be increaſed indefinitely, if more attention were given to raiſing it from ſeed, which is ſeldom done on account of the facility with which it may be propagated by other methods.

Virgil has given ſome of the varieties moſt eſteemed in his time:

" Non eadem arboribus pendet vindemia noſtris,
" Quam Methymnæo carpit de palmite Leſbos.
" Sunt Thaſiæ vites, ſunt et Mareotides albæ:
" Pinguibus hæ terris habiles, levioribus illæ.
" Et paſſo pſythia utilior, tenuiſque lageos,
" Tentatura pedes olim, vincturaque linguam,
" Purpureæ, preciæque, et quo te carmine dicam
" Rhætica? nec cellis ideo contende Falernis.
" Sunt etiam Ammineæ vites, firmiſſima vina,
" Tmolius adſurgit quibus, et rex ipſe Phanæus,
" Argitiſque minor: cui non certaverit ulla,
" Aut tantum fluere, aut totidem durare per annos.
" Non ego te, Dîs, et menſis accepta ſecundis,
" Tranſierim, Rhodia, et tumidis, bumaſte racemis.
" Sed neque quam multæ ſpecies, nec nomina quæ ſint,
" Eſt numerus; neque enim numero comprendere refert:
" Quem qui ſcire velit, Lybici velit æquoris idem
" Diſcere quam multæ Zephyro turbentur arenæ:
" Aut ubi navigiis violentior incidit eurus,
" Noſſe, quot ſonii veniant ad litora fluctus."

Pliny has been very copious upon this ſubject, but it would ſerve no purpoſe to give a long catalogue of names, which we could not reduce to the ſorts with which we are now acquainted.

The oldeſt liſt of Grapes which we have in Engliſh is that of Parkinſon in 1629.

1, 2. Our ordinarie Grape both white and red, which excelleth Crabs for Verjuice, and is not fit for wine with us.

3. The white Muſcadine; very great, ſweet, and firm, ſome of the bunches have weighed ſix pounds, and ſome of the Grapes half an ounce.

4. The red Muſcadine as great, chiefly differing in colour.

5. The Burlet, very great and white, fitter for verjuice than wine, except in a hot year, when it is pleaſant.

6. The little black Grape that is ripe very early.

7. Raiſin of the Sunne Grape, very great and in very great cluſters, reddiſh when ripe, yet in an extraordinarie hot yeare, it hath got a little blewneſſe caſt over it: but naturally verie blew.

8. The Curran Grape, or the Grape of Corinth, the leaſt of all; beareth both few and verie ſeldome with us. There is another ſort that are red or browne, and of a ſour taſte.

9. The Greeke wine Grape, blackiſh and very ſweete.

10. The Frontignack: white, verie ſweete and delicate, as the wine declareth, that ſmelleth as it were of Muſke.

11. The ſquare Grape; not fully round but ſided.

12. The Damaſco; great, white and very ſweete.

13. The Ruſſet; reaſonable faire, exceeding ſweet and whitiſh, with a thick ſkin, cruſted over with a ſhew of aſh colour.

14. The long white Grape, like unto a Pigeon's egge, or as it were pointed pendent like a Pearle.

15. The partie-coloured Grape; reaſonable great, diſcoloured when ripe, ſometimes the whole bunches, and ſometimes but ſome of the Grapes being parted whitiſh, and blacke halfe through, verie variably.

16. The Rheniſh wine Grape; white, and endureth the cold of winter when it commeth earely, more then the Muſcadine, and is nothing ſo ſweete.

17. The White wine Grape, is very like unto the preceding, the ſoile only and climate adding more ſweetneſſe.

18. The Claret wine Grape is altogether like the white, but reddiſh, which lying bruiſed upon the ſkins before they are preſſed, give that Claret tincture to the wine.

19. The Teint; deeper and darker, whoſe juice is of ſo deepe a colour, that it ſerveth to colour other wine.

20. The Burſarobe; faire, ſweete and white: of much eſteeme about Paris.

21. The'Alligant; verie ſweete, giving ſo deep and lively a coloured red wine, that no other is comparable to it, and therefore uſually called Spaniard's blood.

22. Blew or blacke Grape of Orleans; giving a darke coloured ſweete wine much commended in thoſe parts.

23. The Grape without ſtones, growing near Aſcalon, the wine whereof is redde, and of a good taſte.

Mr. Ray, in 1688, gives a few of the Grapes, which were then moſt in requeſt in England.

1. The white and red Muſcadine.
2. The ſmall black, or cluſter or Currant-grape.
3. The Canada or Parſly-grape.
4. The Frontignac, white and red.
5. The red and black Orleans.
6. The Raiſin of the Sun Grape.
7. The Burlet.
8. The Grape de Arbois, in Burgundy: large, longiſh, oval, firm but ſweet. This ſort does not ripen early, and is therefore unfit for cold ſituations.
9. The Burſarobe.
10. The Muſcate. Uvæ moſchatæ, Apianæ Plinio, C. Bauh.
11. The Canary Grape: tranſlated hither from the Rhine.

Mr. Ray adds a liſt of the principal wines then in uſe.

French wines: 1. Vin de Paris. 2. Champagne. 3. Common Claret or Graves wine. 4. Burgundy. 5. Common white wine. 6. Frontignac. 7. Orleans. 8. Hermitage.

Spaniſh wines: 1. Canary Sack. 2. Malaga Sack. 3. Sherry Sack. 4. Alicant wine. Not unlike which is Tent wine.

Portugal: Porto-port wine is imported, but rarely. —Madeira wine is chiefly carried to America.

Italian wines: few are imported. 1. Red Florence wine. 2. Verdea, alſo from Tuſcany, white and ſweet. —Wines eſteemed in Italy are, Malvaſia from Crete; Vicentine;

* Woodville.

Digitized by Google

Vicentine; Montefiaſcone; Montepulciano; Syracuſe; and Lacryma Chriſti. Red Muſcadine is alſo imported from Crete.

German wines: are Neccar, Rheniſh, Hock, Moſelle and Baccherac.

For farther information Ray refers to a work of Andrea Baccio, printed at Rome in 1596.

John Rea, in 1702, gives moſt of thoſe in Mr. Ray's liſt, and adds,

1. Blood-red.
2. The red round Lombardy.
3. White Rheniſh.
4. Small white Muſcat.
5. Muſcat of Frontignan.

The Grapes moſt eſteemed in Italy are la Lugliatica and Tremorina.

The fitteſt for England are, white and red Muſcadine, the two ſorts of Frontiniack, Blood-red, and D'Arbois.

The beſt Vines, he ſays, were then on the walls of the Phyſick Garden at Oxford.

This author gives directions for making a Vineyard in England, from Sir Thomas Hanmer. The ſorts he recommends for this purpoſe are the white and red Muſcadine and the Frontiniack. He does not however encourage the planting of Vineyards in England.

John Roſe, who was gardener to king William at St. James's, in the Engliſh Vineyard, printed at the end of Evelyn's French Gardener, 12mo. 1691, mentions a new white Grape, which he ſays he found in his Majeſty's garden at St. James's, with a red wood, and a dark leaf, the fruit of which ripens as ſoon in ſtandard as againſt ſome walls.

Hitherto no heat but that of the ſun had been applied to the ripening of Grapes. Stoves for preſerving curious exotics from hot climates had been introduced ſoon after the middle of the ſeventeenth century; and towards the end of the ſame century artificial fire was applied to raiſing Ananas or Pine-apples. The firſt mention I find made of its application to Vines is by Mr. Laurence in his Fruit-garden Kalendar, 1718: where he ſays he has been informed that the Duke of Rutland, at Belvoir caſtle, has done ſo much juſtice to the Vine, as to have theſe artificial fires conſtantly burning behind his ſlope walls from Lady-day to Michaelmas; whereby he is rewarded with the largeſt Grapes, and even the beſt Frontignacs in july.

I have not ſeen them, ſays Mr. Laurence; but it is eaſy to conceive, that by the help of Stoves at convenient diſtances, and cavities in the ſtructure of the wall to convey the heat to all parts, the deſireable purpoſe of early, large, and good Grapes muſt be attained; eſpecially if the conſtant care of matting them at night be not neglected; without which all would quickly be ſpoiled by the cold and perpendicular dews or froſts, that fall ſo frequently in april and may.

Our modern forcers of Grapes, will laugh at ſuch improvement. It is however a conſiderable ſtep from Maſter Parkinſon's blanket [t].

But to return to our varieties: Bradley, in 1724, gives a liſt of forty-nine Grapes, which are moſt eſteemed in France; but as he does not pretend to reconcile theſe with our Engliſh catalogues, I will not ſet them down here, but proceed to Mr. Miller's, and ſubjoin ſome from the lateſt and moſt approved writers on the ſubject.]

N. B. *The letter* (h) *diſtinguiſhes the Grapes proper for a Hothouſe; the letter* (v) *for a Vinery; and the letter* (w) *for a common Wall.*

1. July Grape, or Morillon noir hatif. *Duham.* 2. 264. *n.* 1. *Speechly n.* 37. *Forſyth n.* 1. *Bradley n.* 1. Berry ſmall, round, black, growing looſe on the bunches, which are ſmall, but many. Juice ſugary, with little flavour. Principally eſteemed for ripening early without fire heat. Mr. Miller ſays, the beginning of auguſt; Mr. Forſyth, ſeptember.

2. The black Sweet-water. *Speechly n.* 17. *Forſyth n.* 20. Berry ſmall, roundiſh, growing cloſe in the bunches, which are ſhort. Skin thin, juice very ſweet. Birds and flies are very apt to devour them if they are not guarded: they are alſo ſubject to crack. This ripens ſoon after the preceding. *v. w.*

3. The white Sweet-water. *Speechly n.* 16. *Forſyth n.* 19. Berry large and round when in perfection. Juice ſugary, but not vinous. It is apt to have very ſmall berries among the large ones.—It is eſteemed an excellent Grape, the juice being very agreeable; the ſkin and fleſh very delicate. In ſome ſituations, on the ſide next the ſun, the berries are clouded with a ruſſet colour, and are then generally moſt admirable. This Grape is forced in Holland preferably to any other. It is by the Dutch called Parel druyf. *Speechly h. v. w.*

4. Chaſſelas Blanc, or Royal Muſcadine. *Duham. n.* 2. *t.* 1. ? or D'Arboyce, *Speechly n.* 29. *Forſyth n.* 2. An excellent Grape; the bunches generally large, and at the upper part having two ſmaller ſide bunches or ſhoulders. Berries round, white, when perfectly ripe turning to an amber colour. Juice rich and vinous. It ripens in ſeptember; but if carefully preſerved, will hang very late, and become excellent.—The berry is of a moderate ſize, with a thin ſkin, and a juicy ſoft fleſh. The bunches ſometimes weigh ſix or ſeven pounds. The Vine is very diſtinguiſhable by the wood and foliage, generally growing remarkably groſs and ſtrong. *Speechly. h. v.*

5. The Chaſſelas Muſqué, or le Cour Grape, by ſome Frankindal. *Duham. n.* 4. Excellent, and generally ripens well in England on a good-aſpected wall. Berries like thoſe of the preceding in ſhape, ſize and colour; but fleſhy with a little muſky flavour. It ripens in ſeptember.—Mr. Speechly ſays, that he had his Black Muſcadine, *n.* 28. from Holland, by the name of Frankendale. See *n.* 19.

6. The Black Cluſter, or Meunier Grape, ſo called from the hoary down of the leaves in ſummer. For the ſame reaſon Speechly calls it Miller's Burgundy, n. 33. And Forſyth, the Miller Grape. Morillon taconné, *Bradley n.* 2. It is a good fruit, and ripens well here. The bunches are ſhort; the berries oval, and very cloſe, ſo that many of the inner ones continue green, when thoſe on the outſide are perfectly ripe. It is by ſome called the Burgundy Grape, and ripens in ſeptember.—Speechly adds, that the ſkin and fleſh are delicate, the juice ſweet and pleaſant. *v. w.*

This author has another that he calls Small Black Cluſter, n. 34. the berries and bunches of which are little different from Miller's Burgundy, but the leaves have leſs down, and are ſomewhat ſmaller. The fruit is ſweet and delicate, and is ſometimes called the Burgundy Grape. See Forſyth *n.* 24.

7. The Auvergne, or true Burgundy Grape, ſometimes called Black Morillon. *Forſyth n.* 44. Le Bourguignon, *Bradl. n.* 24?—An indifferent fruit for the table, but one of the beſt for making wine. Berries oval, and hanging looſer on the bunches than in the Cluſter Grape, ripen more equally.

8. The Corinth or Currant Grape. *Duham. n.* 14. *t.* 7. *Forſyth n.* 49. Raiſin de Corinthe *Bradl. n.* 18. Berry ſmall, roundiſh, generally without ſtone, of a deep black colour, and much cluſtered on the bunches, which are ſhort. It has a ſugary juice, and ripens in ſeptember, but will not laſt long. *h. v.*

[Richard Hakluyt, in his Remembrances, 1582, informs us that it is ſaid, ſince we traded to Zante, that the plant which beareth the *Coren* is brought into this realm from thence.

I have heard thoſe who have eaten the fruit ripe in that Iſland, ſpeak of it with exquiſite delight.

Mr. Speechly has a White Corinth Grape, with a ſmall round berry, thin ſkinned, having a very delicate juicy fleſh, of an agreeable flavour. The berries when perfectly ripe, are tranſparent, ſo that the ſeeds appear very diſtinctly. N. 48. *Forſ. n.* 30. This therefore differs from the black Zante Grape, which ſeldom has any ſeeds.

Bradley has both a red and a blue Curran Grape, beſides the common ſort.]

9. The Red Chaſſelas. *Forſyth n.* 51. Very like the White (n. 4.) in ſize and ſhape, but of a dark red colour. It is a very good Grape, but ripens later than the White. See *Bradl. n.* 8.

10. The

[t] Park. parad. p. 401.

Digitized by Google

10. The White Muſcadine. *Speechly n.* 27. White or Common Muſcadine, by ſome called the Chaſſelas. *Forſyth n.* 5. Somewhat like the Chaſſelas, (n. 4.) but the berries are ſmaller and hang looſer on the bunches, which are longer but not ſo thick. The juice is ſweet, but not ſo rich.—It is however the beſt Grape that we have for a common wall, and is a great bearer. *Forſyth.* It is often eaten before it is well matured, but when well perfected is an exceeding fine Grape. *Speechl.*

11. Black Frontinac, or Muſcat noir. *Duham. n.* 9. *Forſyth n.* 15. *Bradl.* 13. 14. Blue or Violet Frontinac. *Speechly n.* 14. Berries round of a good ſize, looſe on the bunches, yet do not ripen equally; when fully ripe they are very black, and are covered with a meal or flue like the Plum: the juice is very rich and vinous. Bunches ſhort. It ripens at the end of ſeptember or beginning of october.

12. The Red Frontinac, or Muſcat rouge. *Duham. n.* 7. *t.* 4. *Forſyth n.* 16. *Bradl. n.* 12. An excellent Grape when fully ripe, but unleſs the ſeaſon proves very warm, they rarely ripen without artificial heat in England. Bunches longer than thoſe of the former, the berries large and round, when fully ripe of a brick colour, but when unripe gray with a few dark ſtripes. This is then taken to be a different kind commonly called Griſley Frontinac: but it is the ſame Grape. The juice of this has the moſt vinous flavour of all the ſorts, and is greatly eſteemed in France. *v.*

Both Speechly (n. 12.) and Forſyth (n. 18.) have a Grizzly Frontinac, which they diſtinguiſh from this. The Red Frontinac of the former (n. 15.) is different from Miller's, and he ſays is undoubtedly the true one. Berries of a moderate ſize, round, of a fine red colour, and high flavour. They grow cloſe upon the bunches, which are of a moderate ſize. He had ſeen only two or three bunches, produced here laſt ſummer from a plant which came from France the preceding year, growing in a pot.

13 White Frontinac. Muſcat Blanc. *Duham. n.* 6. *t.* 3. *Speechly n.* 11. *Forſyth n.* 17. Bunches larger than either of the former, berries round, ſo cloſely cluſtered that unleſs they are carefully thinned early in the ſeaſon they will not ripen; and the moiſture will be detained in the autumn, which will cauſe them to rot. Juice excellent; and when the fruit is perfectly ripe, it is inferior to none. *h. v. w.*

14. Alexandrian Frontinac, or Muſcat d'Alexandrie, by ſome called Muſcat of Jeruſalem. *Duham. n.* 10. *t.* 5. White Muſcat of Alexandria. *Speechly n.* 1. *Forſyth n.* 6. Berries oval, hanging looſe on the bunches, which are long and not ſhouldered. There are two ſorts, one with white, the other with red berries; their juice is very rich and vinous, but they ſeldom ripen in England without artificial heat.—This Grape is in great eſtimation, and is more generally planted in hot-houſes than any other ſort. When perfectly ripe, the berries are of a fine amber colour: the ſkins are thick; the pulp hard, and not very juicy, but of a high muſky flavour. *Speechly.*

15. Red Hamburgh. Berries inclined to oval, thin-ſkinned, dark red, with a juicy delicate fleſh, that has a rich vinous flavour. Size middling. Bunches large. End of october or in november. *h. v. Speechly n.* 19. *Forſyth n.* 22. It is ſometimes called the Gibraltar Grape.

16. Black Hamburgh. Like the preceding, but black. Mr. Speechly remarks, that the ſkin is thick, and the pulp hard; but that it is a valuable Grape, being a good-flavoured fruit, and a plentiful bearer.—Mr. Miller ſays it is by ſome called the Warner Grape.

It ripens with the former. *h. v. Speechly n.* 18. *Forſyth n.* 21.

17. St. Peter's Grape. *Speechly n.* 43. *Forſyth n.* 47. Berry large, oval, deep black. Bunches very large, and make a fine appearance at the table, but the juice is not rich, and it ripens late in the year.—Mr. Speechly ſays, the berry is nearly globular, the ſkin thin, and the pulp very delicate and juicy; as it is very apt to crack, it is not generally planted in forcing-houſes, *v.* He has another (n. 44.) which he calls Black Grape from Paleſtine. It is like the St. Peter, but does not crack in the hot-houſe.

The leaves are much more divided than thoſe of the other ſorts, approaching to the Parſley-leaved Grape.

The Claret Grape, Bourdelais or Verjuice Grape, the Raiſin Grape, the ſtriped Grape, and many others which never come to perfection here, are not worthy of any place in gardens, unleſs for the ſake of variety; for even when they have the aſſiſtance of heat to bring them to maturity, their juice is harſh, and without flavour.

[Since Mr. Miller's time many new Grapes have been introduced; and the luxury of forcing has been carried to ſuch an extent, that ſeveral ſorts are now cultivated which were then neglected, as they would not ripen kindly on walls, or by the common mode of treatment then uſed.

The choiceſt of theſe, from the catalogues of Mr. Speechly and Mr. Forſyth are here added.

18. The Malmſey Muſcadine. *Sp. n.* 30. *Forſ. n.* 3. Malvoiſee Muſquée. *Bradl. n.* 15. It ſomewhat reſembles the Royal Muſcadine. (n. 4.) The juice is very ſweet, and of a high flavour. It is a good bearer and a very fine Grape. *w. v.*—Bradley ſays it is one of the richeſt muſked Grapes; comes from Montferrat, and grows plentifully about Turin.

19. The Black Muſcadine. *Sp. n.* 28. *Forſ. n.* 4. Muſcat noir. *Bradl. n.* 13. Berries and bunches ſomewhat ſmaller than in the White Muſcadine. (n. 10.) Very prolific, and makes a fine appearance, on account of the black berries being powdered with a blueiſh bloom; but the pulp is not ſo delicate and juicy as the white. *b. v.*

Mr. Speechly ſays he procured a plant of this Grape from Holland by the name of Frankendale.

20. The Red Muſcat of Alexandria. *Forſ. n.* 7. Muſcat rouge. *Bradl. n.* 12. Reſembles the White; (n. 14.) only the berries are red. *b.*

Bradley ſays, it requires a good deal of ſun to bring it to perfection, but is then one of the beſt Grapes.

21. The White Muſcat from Lunel. *Sp. n.* 49. *Forſ. n.* 8. Berries large and oval, when perfectly ripe of a fine amber colour, ſometimes clouded with brown or ruſſet, eſpecially on the ſide next the ſun. Skin thin, and pulp delicate, full of a vinous juice. This Vine is a plentiful bearer and highly eſteemed. *b. v.*

22. The Black Muſcadel. *Sp. n.* 8. *Forſ. n.* 9. Berries large, oval, black; with a thin ſkin, and a delicate juicy fleſh. *b.*

The ſame bunch contains berries of different ſizes, ſome of them very large and long, but ſomewhat compreſſed and flat at the ends. The leaves change in autumn to a beautiful ſcarlet.

23. The Red Muſcadel. *Sp. n.* 9. *Forſ. n.* 10. Berries large, oval, of a beautiful red colour, with a thick ſkin and hard fleſh, ſomething like the Raiſin Grape. The bunches frequently weigh ſix or ſeven pounds, and are moſt elegantly formed of equal berries. It is one of the lateſt ripe. *b.*

The leaves change in autumn to a beautiful red and green.

24. The Black Damaſcus. *Sp. n.* 2. *Forſ. n.* 11. Berries large, round, black, with a thin ſkin, and a delicate, rich, juicy pulp, of an exquiſite flavour. *b.*

The ſame bunch commonly has berries of different ſizes; the ſmall ones, without ſtones, and the large ones with only one. It is a late Grape, but a moſt excellent and very valuable ſort.

25. The Black Tripoli. *Sp. n.* 3. *Forſ. n.* 12. Nearly allied to the preceding, but the berries are all large and equal, with one ſtone in each. It is a truly valuable late Grape. *b.*

The foliage in both theſe is ſimilar, and in autumn beautiful.

26. The black Spaniſh or Alicant Grape. *Sp. n.* 26. *Forſ. n.* 13. Groſnoir d'Eſpagne, *Bradl. n.* 37. Berries inclining to an oval ſhape, moderately large and black, on exceedingly long unſhouldered bunches. Skin thick, and the ſeeds uncommonly large. Pulp ſoft, juicy, and of an agreeable flavour. It is a pretty good fruit, and is ſometimes called the Lombardy Grape. *b. v.* See *n.* 42.

The leaves in autumn are beautifully variegated with red, green and yellow.

Digitized by Google

The moſt excellent Spaniſh Wine is made from this Grape.

27. The Black Liſbon. *Sp. n.* 46. *Forſ. n.* 14. Berries large, globular, black, thin-ſkinned, and juicy. Bunches large-ſhouldered, reſembling the Black Hamburgh. It is a good Grape. *b. v.*

28. Grizzly Frontinac. *Sp. n.* 12. *Forſ. n.* 18. Berries round, ſomewhat larger than the White, (n. 13.) brown, red and yellow. It has a high, muſky, perfumed flavour. *b. v.*

29. The White Hamburgh. *Sp. n.* 20. *Forſ. n.* 23. Berries large, oval, with a thick ſkin and hard fleſh. It is a plentiful bearer, and forms large bunches; but is not ſo valuable as the Black or Red Hamburgh, (n. 15. 16.) It is ſometimes called the Portugal Grape. *b.*

30. The large Black Cluſter. *Sp. n.* 35. *Forſ. n.* 25. Berries larger and more oval than the ſmall; (ſee *n.* 6.) with a juice of a harſh rough taſte. *v.*

Mr. Speechly ſays it was ſent him from Liſbon, and that he was aſſured it is the Grape of which Port wine is made.

31. The White Grape from Alcobaca. *Sp. n.* 10. *Forſ. n.* 26. Berry large, oval, white, with a thin ſkin and juicy pulp; on large and long bunches, without ſhoulders. *v.*

It was ſent to Mr. Speechly, with many others, from Portugal, by Gerrard De Viſme, Eſq.

32. The White Morillon. *Sp. n.* 36. *Forſ. n.* 27. Berry oval, white, of a moderate ſize, and delicate juicy pulp, growing cloſe on the bunches, which are ſmall. Leaves ſoft, covered with down on the under ſide, ſomewhat ſimilar to the genuine Tokay Grape, to which it appears to be nearly allied.

33. Early White Grape from Teneriffe. *Sp. n.* 42. *Forſ. n.* 28. Berries round, middle-ſized, with a thin ſkin, and delicate juicy pulp, of an extraordinary ſweetneſs. The berries and bunches much reſemble the common Muſcadine, to which it appears to have a near affinity. *v. w.*

34. The Aleppo Grape. *Sp. n.* 4. *Forſ. n.* 31. Berries middle-ſized, roundiſh, with a thin ſkin, and delicate juicy fleſh of an exquiſite vinous flavour. Colour various, white, black, but the major part ſtriped in the ſame bunch, ſometimes one half is white and the other half black, and the colours never intermix, but are divided by ſtraight lines. The leaves in autumn are very curiouſly ſtriped with green and yellow, ſomewhat ſimilar to the Aleppo Lettuce. *b. v.*

35. The Red Grape from Syracuſe. *Sp. n.* 5. *Forſ. n.* 32. Berries very large, oval, ſomewhat irregularly formed; hanging looſely on the bunches, which are pretty large. This is a noble Grape, but little known in this country. *b.*

36. Le Cocoeur or Morocco Grape. *Sp. n.* 6. *Forſ. n.* 33. Berries large, ſomewhat heart-ſhaped, of a tawny grizzly colour; often unequally ſized: they never contain more than one ſtone, and the ſmall ones have none. The pedicels are ſhort, and ſingularly large. It is a much-eſteemed Grape, and very ſcarce. *b.*

37. The Golden Galician. *Sp. n.* 7. *Forſ. n.* 34. Berries large, oval, with a hard fleſh but of a tolerable flavour. They and their footſtalks are of a light yellow colour. *b.*

38. The Black Raiſin Grape. *Sp. n.* 39. *Forſ. n.* 35. Berries large, oval, with a thick ſkin and a firm fleſh. It forms long handſome bunches. *b.*

39. The White Raiſin Grape reſembles the preceding, except that the berries are white.

Mr. Twiſs in his travels through Spain and Portugal, informs us, that Raiſins are cured theſe two ways: firſt, by cutting the ſtalk of the bunches half through, when the Grapes are almoſt ripe, and leaving them ſuſpended on the Vine by their ſtalks. The ſun, in this ſtate, candies them, and when they are dry they are packed up in boxes.—Secondly: when the Vines are pruned, the tendrils are preſerved till the time of vintage: a great fire is then made, wherein the tendrils are burnt, and in the lye, made of their aſhes, the newly-gathered Grapes are dipt, after which they are expoſed to the ſun to dry.

Mr Swinburne, in his travels through Spain, ſays that the Raiſins dried upon the coaſt of Valencia are dipped in a lye of wine and aſhes. *Speechly p* 14. *note.*

40. The Malvoiſe, ſometimes called the Blue Tokay. *Sp. n.* 21. *Forſ. n.* 37. La Malvoiſie or Malmſey Grape. *Bradl. n.* 41. Berries ſmall, inclining to oval, brown powdered with a blue bloom; ſkin thin, and fleſh delicate, full of a vinous juice. *b. v.*

Bradley ſays it bears well, and though the berry is ſmall, it is extremely rich and high flavoured; that it ripens early, and is ſo full of juice that he eſteems it the moſt melting of all Grapes.

He has two other Malvoiſies, red and white, but he eſteems the firſt the beſt.

41. The genuine Tokay. *Sp. n.* 22. *Forſ. n.* 38. White, inclining to oval, rather cloſe on the bunch, which is of a moderate ſize: ſkin thin, and pulp delicate, abounding with a very agreeable juice. The leaves on the under ſide are covered with a fine ſoft down, like ſattin. The Duke of Portland received it from Hungary. *b. v.*

42. The Lombardy. *Sp. n.* 23. *Forſ. n.* 39. Berry large, inclining to oval, of a beautiful flame-colour. The bunches are regularly formed with ſhoulders, and frequently weigh ſix or ſeven pounds. *b. v.*

The leaves are much divided, and their upper ſurface is of a deep green colour. This is by ſome called the Rheniſh Grape, and by others the Flame-coloured Tokay.

43. The Smyrna. *Sp. n.* 24.. *Forſ. n.* 40. Berry large, red, oval, with thin ſkin and delicate juicy fleſh; on long bunches with ſhoulders looſely connected. The leaves in autumn have purple edges. It is a good Grape, but little known in this country. *b. v.*

44. The Brick Grape. *Sp. n.* 25. *Forſ. n.* 41. Berries ſmall, inclining to oval, of a pale red or brick colour; growing cloſe on the bunch, which is very ſmall. It is a very ſweet Grape, but not much eſteemed. *v. w.*

45. The Claret Grape. *Sp. n.* 31. *Forſ. n.* 42. Berries ſmall, black, inclining to oval, growing cloſe, in ſmall bunches: the juice is blood-red, of a harſh taſte, excepting the Grapes are perfectly matured, and then it may be conſidered rather as an agreeable delicate fruit. The leaves change to a ruſſet-red early in ſummer, and to a deep red in autumn. *b. v.*

46. The Syrian Grape. *Sp. n.* 32. *Forſ. n.* 43. Berries white, large, oval, with a thick ſkin, and a firm hard fleſh; on well-formed bunches enormouſly large. It is very prolific, and when well perfected, may be called a very eatable fruit; it may alſo be kept without difficulty many weeks longer than any other ſort. They may thus be had in perfection in january and ſometimes even in february. *b.*

This is ſuppoſed to be the ſort of Grape which the twelve ſpies, who were ſent by Moſes to view the land of Canaan, cut down by the brook of Eſhcol, and bare it between two upon a ſtaff. (Numb. 13. 23.) How large the bunch might be we are not told; but Strabo teſtifies that the Vines in Margiana and other places were ſo big, that two men could ſcarcely compaſs them with their arms, and that they produced bunches of Grapes two cubits or a yard long. And Huetius informs us, that Crete, Chios and other iſlands of the Archipelago afford bunches of ten, and ſometimes of thirty-ſix or forty pounds weight. Nay even in this country, a bunch of the Syrian Grape was produced at Wellbeck under the care of Mr. Speechly, that weighed nineteen pounds and an half. Ignorant perſons, judging from the ordinary ſize of a bunch of grapes, have attempted to throw a ridicule upon the circumſtance of conveying a ſingle bunch between two men. Suppoſing the branch with its cluſter to have weighed forty or fifty pounds, it might certainly have been carried by one man: but as it was to be exhibited to the people, it was proper that the fruit ſhould be preſerved fair, whole and unbruiſed, which it could not have been without carrying it in the manner they are related to have done. Accordingly when the Duke of Portland ſent his large cluſter to the Marquis of Rockingham as a preſent, it was conveyed to Wentworth houſe, a diſtance of more than twenty miles, by four labourers, who carried it, ſuſpended on a ſtaff in pairs, by turns. Its greateſt diameter was nineteen inches and an half,

Digitized by Google

its circumference four feet and an half, and its length twenty-one inches three quarters [u].

47. Cat's Grape. *Sp. n.* 38. *Forſ. n.* 45. Berries ſmall, oval, greeniſh white, with a thin ſkin, and ſoft juicy pulp, growing cloſe on ſmall bunches. Taſte very diſagreeable unleſs perfectly ripe, and then it is very ſweet, *b. v.*

48. The Damſon Grape. *Sp. n.* 41. *Forſ. n.* 46. Berries very large, oval, of a beautiful purple colour, growing looſely on large bunches. Leaves large, thick, and ſucculent, having ſomething of the appearance of green leather. *b.*

49. The Greek Grape. *Sp. n.* 47. *Forſ. n.* 48. Berries of a moderate ſize inclining to oval, bluiſh white, growing cloſe in moderately-ſized handſome bunches. It is a delicate fruit juſtly eſteemed. The leaves grow on very ſhort footſtalks, and bear a reſemblance to thoſe of the Sweetwater. *b. v.*

50. The Cornichon. *Sp. n.* 50. *Forſ. n.* 50. Berries white, with a thick ſkin, and a firm ſweet fleſh. Their ſhape is remarkable, tapering from the ſtalk, but not in a regular manner, and ending in a blunt point, according to the French name, ſomething like a horn; but its figure is more like the long end of a ſmall fiſh's bladder. *b.*

51. The new Muſcat of Jeruſalem. Introduced by Mr. Phillip Miller about thirty-ſix years ago, (1766) and now in the Botanic Garden at Chelſea. Berries large, round, red, in fine ſeaſons the ſize of a gooſberry: but as it does not ripen well on a wall in this country, it might be worth while to try it in a hot-houſe or vinery. *Forſyth n.* 52.

52. The Black Prince. Berries large; bunches alſo large, in a favourable ſeaſon weighing a pound and half on walls. It very well deſerves a place in the hot-houſe and vinery. Ripe in october, and will hang till the middle of november. *Forſyth n.* 53.

Mr. Speechly ſays he might add two or three ſeedling Grapes that have borne fruit: one the produce of the Black Frontinac, impregnated by the White Sweetwater, which may be conſidered as a valuable ſort. The berries are black, but of unequal ſizes. It ripens early.

Mr. Forſyth alſo adds ſeveral names to his liſt, without any deſcription or obſervation. Some of them are mere varieties of varieties; and of ſuch there is no end. They are however the following:

Black Frankindale. See *n.* 5. and 19.
Black Gibraltar. See *n.* 15. for the Red.
Black Muſcat of Alexandria. See *n.* 14.
The Miller Grape. See *n.* 6.
New White Sweetwater. See *n.* 3.
Paſſe Muſk.
Pearl Muſcadine.
Red Conſtantia.
Red Raiſin. See the Black and White, *n.* 38 and 39.
Sir Abraham Pitches's Fine Black.
Weſt's St. Peter. See *n.* 15. It is common for perſons who raiſe new varieties, to add their own names to an old one.
White Conſtantia.

From this and the Red is made the famous Conſtantia wine, ſo called from a place near the Cape of Good Hope. But Colonel Paterſon informs us that this Vine, when tranſplanted to but a ſmall diſtance from that ſpot, produces a very inferior wine. The ſituation of the place is rather low, but rather more elevated than other parts of the diſtrict; and the ſoil is a light ſandy loam.

Mr. Speechly ſays, that he had his Black or Purple Frontinac, *n.* 13. from the Cape by the name of Black Conſtantia. The berries, he ſays, are black, but when produced under glaſs are generally dark purple: they are moderately large, round, and of a moſt excellent flavour. The bunches are very long. It has been generally called the Red Frontinac (See *n.* 12.) and is one of our very beſt Grapes.

Seleƈt Vines for a ſmall Garden.

The White Muſcadine. White Sweetwater. Black Sweetwater. Large and Small Black Cluſter. The Miller Grape.

St. Peter's and the Black Hamburgh, will do very well in favourable ſeaſons [x].

Mr. Speechly remarks, that the leaves of white Grapes change to a yellow colour. Thoſe of the Claret grape change to a dark purple and ruſſet green early in the ſeaſon. Thoſe of the Blue Frontinac and Black Muſcadine change late to a beautiful ſcarlet and yellow intermixed. The leaves of the Aleppo Grape are curiouſly ſtriped with red, green and yellow: the Muſcadel, Smyrna, Morocco, Black Damaſcus, Grizzly Frontinac, and Black Spaniſh or Alicant, are alſo exceedingly beautiful.

The leaves of the pale-red and grizzly Grapes are not always tinged with red; but whenever the leaſt tinge of red, purple or ſcarlet appears on the leaves of the Vine at the time of their maturation, it is a certain ſign that the Grape will be grizzly, red, or black. By attending to this, we may aſcertain at the end of the firſt year, the colour which the Grapes of ſeedling Vines will have.

β. The Currant Vine has been noticed among the varieties: it is not unuſual to have ſome berries without ſtones in other varieties: and we have dried Grapes frequently imported under the name of Sultana Raiſins, that are eſteemed on that account.

2. Branches purpliſh, ſmooth. Leaves equal in length and breadth, cordate at the baſe; ſegments lanceolate, attenuated, the lateral ones with lanceolate teeth on the outſide, the middle one deeply ſerrate on each ſide above. Stipules lanceolate. Racemes an inch long: with approximating umbellets. Native of Virginia [y]. Vahl ſays he had it from the Paris Garden.]

3. Trunk woody, ſending out many ſlender branches, furniſhed with branching tendrils, by which they faſten themſelves to trees. Flowers in bunches like thoſe of the other ſorts; ſucceeded by berries or Grapes of an auſtere taſte.

[Size of the common Vine but with gray hairs ſcattered over the whole. Leaves undivided, almoſt ſmooth above, but villoſe and veined beneath with thick veſſels. It has a ſimple tendril from the axils, and ſimple raceme from the middle of the tendril [z].

Leaves ovate, acute, alternate, on reddiſh petioles. Flowers white, like thoſe of the common Vine and equal; on ſmall lateral racemes. Berries round, browniſh-green, ſmall, watery, acid, eatable [a].

It produces a great quantity of ſmall black Grapes in the lower hills of Jamaica; but they are of a rough taſte, and would doubtleſs make an excellent red wine, if properly managed. It ſeems to thrive beſt in the Red hills. In Jamaica it is known by the name of Water-withe. When it grows luxuriant, as it generally does in the higher woody lands, it is ſo full of juice, that a piece of about three feet will yield near a pint of clear taſteleſs water; which has ſaved the lives of many who have wandered long in the woods, without any other refreſhment of a liquid ſort [b].

Native both of the Eaſt and Weſt Indies, and Cochinchina.

4. Stem round, aſh-coloured, ſmooth. Leaves acute, villoſe beneath, eſpecially along the nerves. Petioles filiform, half an inch long. Panicles without tendrils, with glomerate floſcules. Native of Japan [c]. At firſt not diſtinguiſhed by Thunberg from the preceding.]

5. Leaves large, covered with a white down on the under ſide. Berries round and black, with a rough-flavoured juice.

[Stem very long, and ſlender, branched, and climbing by tendrils. Leaves ſubtrilobate and entire, ſerrate-toothed, with a ruſt-coloured down beneath, rough, alternate, on long petioles. Flowers very ſmall, pale, on ſhort lateral racemes. Berries round, black, acid but eatable.

From the fermented Grapes of this and the Indian Vine a tolerably good ſpirit is diſtilled in Cochinchina [d].

[u] Speechly, p. 41. and Pegge's note.

Native

Digitized by Google

Native of North America, Amboyna, Cochinchina and Japan.—Introduced in 1656, by Mr. John Tradescant, jun[e].]

6. Stem shrubby climbing by tendrils. Berries black, with a flavour resembling the scent of a fox, whence the name. [Native of Virginia. Cultivated 1656, by Mr. John Tradescant, jun[f].

7. Stem climbing, somewhat angular, smooth and even, jointed, knobbed: branches alternate, spreading, resembling the stem. Leaves alternate; the lower ones larger, five-lobed; upper gradually less, three-lobed with the lobes gashed and toothed; uppermost undivided, serrate, deep green above and even, beneath paler with the veins standing out and rugged. Petioles round, have a brown downy groove above, spreading, as long as the leaf from an inch to a finger's length. Tendrils opposite to the peduncles, bifid, smooth. Flowers axillary, in subdichotomous smooth panicles. Corolla white. Berries globular, green, smooth, the size of a pea, containing two or sometimes three or four seeds, surrounded by a hardish white rind, subcordate, attenuated below, subbilocular. Native of Japan, flowering there in july and auguſt[g].]

8. The stalks and branches of this are like those of the common Grape, but the leaves are cut into many slender segments. The Grapes are round, white, and disposed in loose bunches. Mr. Miller says, it is supposed to grow naturally in Canada, [but that is probably a mistake, which took its rise from Cornutus having inserted it in his work. It was cultivated by Mr. John Tradescant, jun. in 1656.] But as the fruit has little flavour, and ripens late in autumn, it has been almost banished the English gardens, where at present there are only a few plants preserved for the sake of variety.

[Speechly and Forsyth have a white Parsly-leaved Grape, called also Ciotat, or Ciouta, as Bradley writes it. In his catalogue from France it is named Raisin d'Autriche á feuille de Persil. Berries round, white, of a moderate size, with a thin skin, and delicate juicy pulp, but not of a vinous flavour. The bunches are of a pretty good size, almost similar to the White Muscadine. Bradley adds that it bears pretty well. *Sp. n.* 45. *Forſ. n.* 29. *Bradl. n.* 6.

There is a variety of this with red berries.

9. See Hedera quinquefolia, n. 3.

10. This resembles the preceding species. Stem scandent. Leaves alternate, digitate, on long petioles: leaflets seven, or from five to eight, on petiolets, elliptic, smooth, substantial, mucronate, twice as long as the petiolets. Raceme terminating, very large, formed of alternate spikes, which are simple and subtomentose. Flowers sessile, small, in remote whorls. Calyx five-toothed. Petals cohering at the top, deciduous at the base. Stamens five. Pistil blunt. Therefore it is not either a Hedera or a Cissus. Native of the East Indies[h].

11. Branches purplish, smooth, round. Leaflets in fives, the middle ones subsessile, the rest petioled, the lowest frequently augmented on the outside with a lobe, ovate, acuminate, having four or five large serratures on each side, pale green beneath, two inches long. Peduncles opposite to a leaf, twice bifid. Pedicels umbelled. Flowers small. Native place unknown. Vahl had it from Schumacher[i].]

12. Stem woody, sending out many slender branches, which climb by tendrils. Leaves composed of many smaller winged leaves, divided somewhat like those of common Parsley, of a lucid green on their upper side, but much paler on their under. Flowers axillary in loose bunches, very small, white, composed of five small petals, which expand and soon fall off. They are not succeeded by any fruit in England, but the berries which come from North America, their native place of growth, have generally three seeds in each.

Mr. Rand gave it the name of Reynardsonia, from Samuel Reynardson, Esq. of Hillendon near Uxbridge, who was a great collector of foreign plants, [and cultivated the Pepper Vine there before the year 1700, as we learn from Plukenet[k].] Mr. Miller says, that the characters are not sufficiently known in Europe, to determine its proper genus; for it seldom flowers here, and has never produced any fruit in England. He therefore leaves it in this genus on the authority of Linneus.

PROPAGATION AND CULTURE.

All the sorts of Grapes are propagated either from layers or cuttings, the former of which is greatly practised in England, but the latter is what I would recommend, as being much preferable to the other; for the roots of Vines do not grow strong and woody, as in most sorts of trees, but are long, slender, and pliable; therefore when they are taken out of the ground, they seldom strike out any fibres from their weak roots, which generally shrivel and dry; so that they rather retard than help the plants in their growth, by preventing the new fibres from pushing out; for which reason I had rather plant a good cutting than a rooted plant, provided it be well chosen, and there is little danger of its not growing.

But as there are few persons who make choice of proper cuttings, or at least that form their cuttings rightly in England, so it will be proper to give directions for this in the first place, before I proceed. You should always make choice of such shoots as are strong, and well ripened of the last year's growth: these should be cut from the old Vine, just below the place where they were produced, taking a knot, or piece of the two years wood to each, which should be pruned smooth; then you should cut off the upper part of the shoots, so as to leave the cutting about sixteen inches long. When the piece or knot of old wood is cut at both ends near the young shoot, the cutting will resemble a little mallet, from whence Columella gives the title of Malleolus to the Vine cuttings. In making the cuttings after this manner, there can be but one taken from each shoot; whereas most persons cut them into lengths of about a foot, and plant them all, which is very wrong; for the upper part of the shoots is never so well ripened as the lower, which was produced early in the spring, and has had the whole summer to harden, so that if they take root, they never make so good plants; for the wood of those cuttings being spongy and soft, admits the moisture too freely, whereby the plants will be luxuriant in growth, but never so fruitful as such whose wood is closer and more compact.

When the cuttings are thus prepared, if they are not then planted they should be placed with their lower part in the ground in a dry soil, laying some litter upon their upper parts to prevent them from drying: in this situation they may remain till the beginning of april (which is the best time for planting them) when you should take them out, and wash them from the filth they have contracted; and if you find them very dry, you should let them stand with their lower parts in water six or eight hours, which will distend their vessels, and dispose them for taking root. Then the ground being before prepared where the plants are designed to remain (whether against walls, or for standards, for they should not be removed again,) the cuttings should be planted; but in preparing the ground, you should consider the nature of the soil, which, if strong, and inclinable to wet, is by no means proper for Grapes; therefore where it so happens, you should open a trench where the cuttings are to be planted, which should be filled with lime rubbish, the better to drain off the moisture; then raise the border with fresh light earth about two feet thick, so that it may be at least a foot above the level of the ground, then you should open the holes at about six feet distance from each other, putting one good strong cutting into each hole, which should be laid a little sloping, that their tops may incline to the wall, but it must be put in so deep, as that the uppermost eye may be level with the surface of the ground; for when any part of the cutting is left above ground, as is the common method used by the English gardeners, most of the buds attempt to shoot;

[k] Hort. kew.

so

ſo that the ſtrength of the cuttings are divided to nouriſh ſo many ſhoots, which muſt conſequently be weaker than if only one of them grew; whereas on the contrary, by burying the whole cutting in the ground, the ſap is all employed on one ſingle ſhoot, which conſequently will be much ſtronger; beſides, the ſun and air are apt to dry that part of the cutting which remains above ground, and ſo often prevents their buds from ſhooting.

Then having placed the cutting into the ground, you ſhould fill up the hole gently, preſſing down the earth with your foot cloſe about it, and raiſe a little hill juſt upon the top of the cutting, to cover the upper eye quite over, which will prevent it from drying; this being done, there is nothing more neceſſary, but to keep the ground clear from weeds until the cuttings begin to ſhoot; at which time you ſhould look over them carefully to rub off any ſmall ſhoots, if ſuch are produced, faſtening only the firſt main ſhoot to the wall, which ſhould be conſtantly trained up, as it is extended in length, to prevent its breaking or hanging down; you muſt continue to look over theſe once in about three weeks during the ſummer ſeaſon, conſtantly rubbing off all lateral ſhoots which are produced, leaving only the firſt main ſhoot; and be ſure to keep the ground conſtantly clear from weeds, which, if ſuffered to grow, will exhauſt the goodneſs of the ſoil, and ſtarve the cuttings.

The Michaelmas following, if your cuttings have produced ſtrong ſhoots, you ſhould prune them down to two eyes, which, though by ſome people may be thought too ſhort, yet I am ſatisfied, from ſeveral experiments, to be the beſt method. The reaſon for adviſing the pruning Vines at this ſeaſon, rather than deferring it till ſpring is, becauſe the tender parts of thoſe young ſhoots, if left on, are ſubject to decay in winter, for they are apt to grow late in the year, ſo the tops of their ſhoots are tender, and the early froſts will pinch them, and then they frequently are killed down a conſiderable length, which weakens their roots; but if they are cut off early in autumn, the wounds will heal over before the bad weather, and thereby the roots will be greatly ſtrengthened.

In the ſpring, after the cold weather is paſt, you muſt gently dig up the borders to looſen the earth; but you muſt be very careful in doing this, not to injure the roots of your Vines; you ſhould alſo raiſe the earth up to the ſtems of the plants, ſo as to cover the old wood, but not ſo deep as to cover either of the eyes of the laſt year's wood. After this they will require no farther care until they begin to ſhoot, when you ſhould look over them carefully, to rub off all weak dangling ſhoots, leaving no more than one or two ſhoots, which are produced from the eyes of the laſt year's wood, which ſhould be faſtened to the wall; and from this time, until the Vines have done ſhooting, you ſhould look them over once in three weeks or a month, to rub off all lateral ſhoots as they are produced, and to faſten the main ſhoots to the wall as they are extended in length, which muſt not be ſhortened before the middle or latter end of july, when it will be proper to nip off their tops, which will ſtrengthen the lower eyes; and during the ſummer ſeaſon, you muſt conſtantly keep the ground clear from weeds; nor ſhould you permit any ſort of plants to grow near the Vines, which would not only rob them of nouriſhment, but ſhade the lower part of the ſhoots, and thereby prevent their ripening, which will not only cauſe their wood to be ſpongy and luxuriant, but render it leſs fruitful.

As ſoon as the leaves begin to drop in autumn, you ſhould prune theſe young Vines again, leaving three buds to each of the ſhoots, provided they are ſtrong, otherwiſe it is better to ſhorten them down to two eyes if they are good; for it is a very wrong practice to leave much wood upon young Vines, or to leave their ſhoots too long, which greatly weakens the roots; then you ſhould faſten them to the wall, ſpreading them out horizontally each way, that there may be room to train the new ſhoots the following ſummer, and in the ſpring dig the borders as before.

The third ſeaſon you muſt go over the Vines again as ſoon as they begin to ſhoot, to rub off all danglers as before, and train the ſtrong ſhoots in their proper places, which this year may be ſuppoſed to be two from each ſhoot of the laſt year's wood; but if they attempt to produce two ſhoots from one eye, the weakeſt of them muſt be rubbed off, for there ſhould never be more than one allowed to come out of each eye. If any of them produce fruit, as many times they will the third year, you ſhould not ſtop them ſo ſoon as is generally practiſed upon the bearing ſhoots of old Vines, but permit them to ſhoot forward till a month after Midſummer, at which time you may pinch off the tops of the ſhoots; for if this were done too ſoon, it would ſpoil the buds for the next year's wood, which in young Vines muſt be more carefully preſerved than on older plants, becauſe there are no other ſhoots to be laid in for a ſupply of wood, as is commonly practiſed on old Vines.

During the ſummer you muſt conſtantly go over your Vines, and diſplace all weak lateral ſhoots as they are produced, and carefully keep the ground clear from weeds, as was before directed, that the ſhoots may ripen well; which is a material thing to be obſerved in moſt ſorts of fruit-trees, but eſpecially in Vines, which ſeldom produce any fruit from immature branches. Theſe things being duly obſerved, are all that is neceſſary in the management of young Vines; I ſhall therefore proceed to lay down rules for the government of grown Vines, which I ſhall do as briefly as poſſible. And,

Firſt, Vines rarely produce any bearing ſhoots from wood that is more than one year old, therefore great care ſhould be taken to have ſuch wood in every part of the trees; for the fruit are always produced upon the ſhoots of the ſame year, which come out from buds of the laſt year's wood. The method commonly practiſed by the gardeners in England is, to ſhorten the branches of the former year's growth, down to three or four eyes, at the time of pruning; though there are ſome perſons who leave theſe ſhoots much longer, and affirm that by this practice they obtain a greater quantity of fruit; but however this may be, it is a very wrong practice, ſince it is impoſſible that one ſhoot can nouriſh forty or fifty bunches of Grapes, ſo well as it can ten or twelve; ſo that what is gotten in number, is loſt in their magnitude; beſides, the greater quantity of fruit there is left on Vines, the later they are ripened, and their juice is not ſo rich; and this is well known in the wine countries, where there are laws enacted to direct the number and length of ſhoots that are to be left upon each Vine, leſt by overbearing them, they not only exhauſt and weaken the roots, but thereby render the juice weak, and ſo deſtroy the reputation of their wine.

Wherefore the beſt method is, to ſhorten the bearing ſhoots to about four eyes in length, becauſe the lowermoſt ſeldom is good, and three buds are ſufficient, for each of theſe will produce a ſhoot, which generally has two or three bunches of Grapes; ſo that from each of thoſe ſhoots there may be expected ſix or eight bunches, which is a ſufficient quantity. Theſe ſhoots muſt be laid about eighteen inches aſunder, for if they are cloſer, when the ſide ſhoots are produced, there will not be room enough to train them againſt the wall, which ſhould always be provided for; and as their leaves are very large, the branches ſhould be left at a proportionable diſtance from each other, that they may not croud or ſhade the fruit.

At the winter pruning of your Vines you ſhould always obſerve to make the cut juſt above the eye, ſloping it backward from it, that if it ſhould bleed, the ſap might not flow upon the bud; and where there is an opportunity of cutting down ſome young ſhoots to two eyes, in order to produce vigorous ſhoots for the next year's bearing, it ſhould always be done, becauſe in ſtopping of thoſe ſhoots which have fruit upon them as ſoon as the Grapes are formed, which is frequently practiſed, it often ſpoils the eyes for producing bearing branches the following year, and this reſerving of new wood is what the vignerons abroad always practiſe in their vineyards. The beſt ſeaſon

Digitized by Google

for pruning of Vines is the end of october, for the reaſons before laid down.

The latter end of april, or the beginning of may, when the Vines begin to ſhoot, you muſt carefully look them over, rubbing off all ſmall buds which may come from the old wood, which only produce weak dangling branches; as alſo when two ſhoots are produced from the ſame bud, the weakeſt of them ſhould be diſplaced, which will cauſe the others to be ſtronger: and the ſooner this is done, the better it is for the Vines.

In the middle of may you muſt go over them again, rubbing off all the dangling ſhoots as before, and at the ſame time you muſt faſten up all the ſtrong branches; ſo that they may not hang from the wall; for if their ſhoots hang down, their leaves will be turned with their upper ſurfaces the wrong way, and when the ſhoots are afterwards trained upright, they will have their under ſurface upward; and until the leaves are turned again, and have taken their right poſition, the fruit will not thrive; ſo that the not obſerving this management, will cauſe the Grapes to be a fortnight or three weeks later before they ripen; beſides, by ſuffering the fruit to hang from the wall, and be ſhaded with the cloſeneſs of the branches, it is greatly retarded in its growth; therefore during the growing ſeaſon, you ſhould conſtantly look over the Vines, diſplacing all dangling branches and wild wood, and faſten up the other ſhoots regularly to the wall, as they are extended in length; and towards the middle of june you ſhould ſtop the bearing branches, which will ſtrengthen the fruit, provided you always leave three eyes above the bunches; for if you ſtop them too ſoon, it will injure the fruit, by taking away that part of the branch which is neceſſary to attract the nouriſhment to the fruit, as alſo to perſpire off the crudities of the ſap, which is not proper for the fruit to receive.

But although I recommend the ſtopping thoſe ſhoots which have fruit at this ſeaſon, yet this is not to be practiſed upon thoſe which are intended for bearing the next year, for theſe muſt not be ſtopped before the middle of july, leſt, by ſtopping them too ſoon, you cauſe the eyes to ſhoot out ſtrong lateral branches, whereby they will be greatly injured.

During the ſummer ſeaſon you ſhould be very careful to rub off all dangling branches, and train up the ſhoots regularly to the wall as before, which will greatly accelerate the growth of the fruit, and alſo admit the ſun and air to them, which is abſolutely neceſſary to ripen and give the fruit a rich flavour; but you muſt never diveſt the branches of their leaves, as is the practice of ſome perſons; for although the admitting of the ſun muſt be neceſſary to ripen them, yet if they are too much expoſed thereto, their ſkins will be tough, and it will retard their ripening; beſides, the leaves being abſolutely neceſſary to nouriſh the fruit, by taking them off, the fruit is ſtarved, and ſeldom comes to any ſize, as I have ſeveral times obſerved; therefore a great regard ſhould be had to the ſummer management of the Vines, where perſons are deſirous to have their fruit excellent, and duly ripened.

When the fruit is all gathered, you ſhould prune the Vines, whereby the litter of their leaves will be entirely removed at once, and their fruit will be the forwarder the ſucceeding year.

[*Method of managing Vines againſt flued or hot-walls, commonly called Vineries or Grape Houſes.*

A Vinery or Grape Houſe conſiſts of walls twelve or fourteen feet high, running from eaſt to weſt, furniſhed with ſtoves and proper flues, with a roof and lights of glaſs covering a border of about ten feet in width. See the engraved Elevation, Section and Ground Plan.

Where Vines are intended to be forced at an early ſeaſon, it is uſual to have upright glaſſes, two and an half or three feet high in front, to ſupport the roof, to admit ſun and light to the border, which is generally occupied by low-growing vegetables; but where Grapes are not wanted early, a low wall in front will anſwer as well.

Suppoſing the wall to be twelve feet high, the breadth of the border ten feet, and the height of the upright wall in front three feet, the roof will then form an angle of about 43°; which experience ſhows to be a proper pitch for forcing Vines after the vernal equinox.

A Grape Houſe may alſo be conſtructed on a plan ſimilar to that of a ſingle-pitted Pine-ſtove. The back wall fourteen feet high; the roof ſlanting, and covering an extent of about ſixteen feet; and a flue running from eaſt to weſt near the front wall. Such a building is well calculated not only for Grapes, but for early crops of melons, ſtrawberries, &c.

Glaſs being the principal article of expenſe in forcing fruit; where there is a Peach-houſe, the glaſs-frames may ſerve both for that and the Vinery, provided the buildings are conſtructed of the ſame dimenſions; for as Peaches do not require to be covered with glaſs later than the middle of ſummer, a crop of Grapes may be got by means of the ſame glaſſes after that ſeaſon.

Good crops of Grapes may alſo be obtained from Vines trained againſt walls about ſix feet high, by means of melon-frame glaſſes, if a ſmall ſlanting roof is made of proper dimenſions to receive the glaſſes. A ſmall degree of fire-heat would be of great advantage, and might be applied either by a flued wall, the flue running through the houſe, or by caſt-iron pipes[1].]

The borders againſt theſe hot walls ſhould have the earth taken out two feet deep (provided the ground is dry,) otherwiſe one foot will be ſufficient, becauſe in wet land the borders ſhould be raiſed at leaſt two feet above the level of the ground, that the roots of the Vines may not be injured by the wet. When the earth is taken out, the bottom of the trench ſhould be filled with ſtones, lime rubbiſh, &c. a foot and a half, or two feet thick, which ſhould be levelled and beaten down pretty hard to prevent the roots of the Vines from running downward. The trenches ſhould be made five feet wide at leaſt, otherwiſe the roots of the Vines will in a few years extend themſelves beyond the rubbiſh, and finding an eaſy paſſage downwards, will run into the moiſt ground, and thereby imbibe ſo much wet, as to leſſen the vinous flavour of the Grapes; but before the rubbiſh is filled into the trench, it is a better method to raiſe a nine inch wall, at five feet diſtance from the hot wall, which will keep the rubbiſh from intermixing with the neighbouring earth, and alſo confine the roots of the Vines to the border in which they are planted, ſo that they cannot reach to the moiſture of the ground about them. This nine inch wall ſhould be raiſed to the height of the intended border, ſo will be of great uſe to lay the plate of timber of the frames upon, which will be neceſſary to cover the Vines when they are forced, whereby the timbers will be better preſerved from rotting; and where the borders are raiſed to any conſiderable height above the level of the ground, theſe walls will preſerve the earth of the borders from falling down into the walks; but in carrying up theſe walls, it will be proper to leave little openings about eight or ten feet diſtance, to let the water paſs off, becauſe when the rubbiſh at the bottom of the trench unites and binds very hard, the water cannot eaſily find a paſſage through it; therefore it will be the better method to leave theſe ſmall paſſages in the front wall, leſt the moiſture being confined at bottom, ſhould be pent up as in a ditch, which will be of ill conſequence to the Vines, but theſe openings ſhould be two feet below the ſurface.

When the walls are finiſhed and thoroughly dry, the rubbiſh ſhould be filled in, as before directed; then there ſhould be freſh light earth laid upon it two feet thick, which will be a ſufficient depth of ſoil for the Vines to root in. Theſe borders ſhould be thus prepared at leaſt a month or ſix weeks before the Vines are planted, that they may have time to ſettle. The beſt time to plant them is about the end of march, or the beginning of april, according as the ſeaſon proves early or late. Theſe I would alſo adviſe to be planted with cuttings, rather than rooted plants, for the reaſons before aſſigned, but there ſhould be two cuttings put into each hole, or placed at a nearer diſtance, leſt any of them ſhould fail; for if all ſhould

[1] Speechly, p. 97. and 124.

ſucceed

Digitized by Google

ſucceed, the weakeſt of them may be eaſily drawn out the following ſpring. Theſe cuttings ſhould be well choſen from good bearing Vines, and the ſhoots ſhould be well ripened, otherwiſe they will never make good plants. The diſtance theſe Vines ſhould be allowed to remain is the ſame as for common walls, i. e. about ſix feet. In planting them there ſhould be holes opened with a ſpade, about fouteen or fifteen inches deep, for if there be but three or four inches of good earth under the foot of the cuttings it will be ſufficient; then the cuttings ſhould be laid in the holes a little ſloping, afterward the earth ſhould be filled into the holes, and gently preſſed with the foot to the cuttings, and raiſed in a heap over them, ſo as juſt to cover the uppermoſt eyes of the cuttings; afterward lay a little mulch on the ſurface of the ground about the cuttings, to prevent the ſun and air from drying the earth, and if the ſpring ſhould prove very dry, they ſhould have ſome water once a week, which will be as often as the cuttings require it, for nothing will deſtroy them ſooner than too much water, which rots their bark, and deſtroys them. If theſe cuttings are well choſen, and the inſtructions here laid down duly obſerved, they will make ſtrong ſhoots the firſt ſummer, for I have frequently planted cuttings which have ſhot five feet in one year, but then I carefully rubbed off all the ſide dangling ſhoots as they were produced, and never permitted more than one ſhoot to remain on each cutting, which is what ſhould always be obſerved by thoſe who have the care of Vines. With this management there will be little hazard of the cuttings taking root, for in upwards of five hundred cuttings which I received from Italy, and which had been cut off from the Vines in the beginning of november, wrapped up in moſs, and put on board the ſhip, (which did not arrive at the port of London until march, ſo that they were full four months cut off before they were planted,) there were not twenty of the number which failed, and many of them ſhot about ſix feet the firſt ſeaſon.

As I have directed the pruning of Vines to be performed in autumn (which is without diſpute the beſt ſeaſon for this work,) ſo in preſerving of the cuttings till the planting ſeaſon, I have adviſed them to be cut to their lengths, and their ends laid into the ground, and then covered with litter or moſs to keep the air from them; but ſince I have found it a much better method not to ſhorten the ſhoots, from which the cuttings are to be made, but to lay their ends juſt into the ground, about two inches deep, and ſo leave them at full length, only obſerving to cover them with dry litter or Peas haulm in froſty dry weather, tho' in moiſt weather the covering ſhould not remain on, becauſe it would make the cuttings grow mouldy, which would greatly injure them. Then in the ſpring, when they are to be planted, they ſhould be taken out of the ground, and their upper part cut off, ſo as to reduce them to about fourteen inches in length, according to the diſtance of the buds or eyes; for thoſe cuttings whoſe buds grow pretty cloſe together, need not be left more than one foot long, but in others fourteen or ſixteen inches will be full ſhort. The leaving the upper part of the ſhoots on all the winter is of great ſervice to the cuttings, becauſe when they are cut off in autumn, the air penetrates the wounded part, and greatly injures the other eyes.

The management of theſe Vines, for the three firſt years after planting, being the ſame as is practiſed for thoſe againſt common walls, I ſhall not repeat it in this place, having fully treated of that already; only will obſerve, that during theſe three years, the Vines ſhould be encouraged as much as poſſible, and the ſhoots not left too long, nor too many in number on each root, that they may be duly ripened and prepared for bearing the fourth year, which is the ſooneſt they ſhould be forced; for when any ſorts of fruit-trees are forced by fire too young, they ſeldom continue long in health, ſo that what fruit they produce is ſmall, and not well-flavoured; therefore, in being over haſty to ſave a year or two, very often the whole deſign miſcarries; for unleſs the trees are in a proper condition to bear much fruit, it is not worth while to make fires for a ſmall quantity of ſtarved ill-taſted fruit, the expenſe and trouble being the ſame for ten or twelve bunches of Grapes, as it will be for a hundred or more.

Theſe Vines ſhould not be forced every year, but with good management they may be forced every other year, though it would be better if it were done only every third year; therefore, in order to have a ſupply of fruit annually, there ſhould be a ſufficient quantity of walling built to contain as many Vines as will be neceſſary for two or three years, and by making the frames in front moveable, they may be ſhifted from one part of the wall to another, as the Vines are alternately forced; therefore I would adviſe about forty feet length of walling to be each year forced, which is as much as one fire will heat; and when the Vines are in full bearing, will ſupply a reaſonable quantity of Grapes for a middling family; but for great families, twice this length will not be too much.

In moſt places where theſe hot walls have been built, they are commonly planted with early kinds of Grapes, in order to have them early in the ſeaſon; but this I think is hardly worth the trouble, for it is but of little conſequence to have a few Grapes earlier by a month or ſix weeks, than thoſe againſt common walls; therefore I ſhould adviſe, whenever a perſon is willing to be at the expenſe of theſe walls, that they may be planted with ſome of the beſt kinds of Grapes, which rarely come to any perfection in this country without the aſſiſtance of ſome artificial heat, of which the following ſorts are the moſt valuable.

The Red Muſcat of Alexandria.
The White Muſcat of Alexandria.
The Red Frontinac.
The White Frontinac.
The Black Frontinac.

When the Vines which are planted againſt the hot walls are grown to full bearing, they muſt be pruned and managed after the ſame manner as hath been directed for thoſe againſt common walls, with this difference only, viz. that thoſe ſeaſons when they are not forced, the Vines ſhould be carefully managed in the ſummer for a ſupply of good wood, againſt the time of their being forced, ſo that it will be the better method to diveſt the Vines of their fruit, in order to encourage the wood; for as few of the ſorts will ripen without heat, it is not worth while to leave them on the Vines during the ſeaſon of reſting, except it be the common Frontinacs, which in a good ſeaſon will ripen without artificial heat, but even on theſe, I would not adviſe many Grapes to be left during the years of their reſting; becauſe as the deſign of this is to encourage and ſtrengthen them, therefore all poſſible care ſhould be had that the young wood is not robbed by overbearing; for thoſe years when the Vines are forced, the joints of the young wood are generally drawn farther aſunder, than they ordinarily grow in the open air; ſo that when they are forced two or three years ſucceſſively, the Vines are ſo much exhauſted, as not to be recovered into a good bearing ſtate for ſome years, eſpecially if they are forced early in the ſeaſon; or where great care is not taken in the ſummer to let them have a proper ſhare of free air, to prevent their being drawn too much, and alſo to ripen their ſhoots. Thoſe years when the Vines are forced, the only care ſhould be to encourage the fruit, without having much regard to the wood, ſo that every ſhoot ſhould be pruned for fruit, and none of them ſhortened for a ſupply of young wood, becauſe they may be ſo managed by pruning in the years of their reſting, as to repleniſh the Vines with new wood. Thoſe Vines which are deſigned for forcing in the ſpring, ſhould be pruned early the autumn before, that the buds which are left on the ſhoots, may receive all poſſible nouriſhment from the root, and at the ſame time the ſhoots ſhould be faſtened to the trellis in the order they are to lie; but the glaſſes ſhould not be placed before the Vines till about the middle or end of january, at which time alſo the fires muſt be lighted, for if they are forced too early

in

Digitized by Google

in the year they will begin to ſhoot before the weather will be warm enough to admit air to the Vines, which will cauſe the young ſhoots to draw out weak, and thereby their joints will be too far aſunder, conſequently there will be fewer Grapes on them, and thoſe bunches which are produced will be ſmaller than when they have a ſufficient quantity of air admitted to them every day.

If the fires are made at the time before directed, the Vines will begin to ſhoot the middle or latter end of february, which will be ſix weeks earlier than they uſually come out againſt the common walls, ſo that by the time that other Vines are ſhooting, theſe will be in flower, which will be early enough to ripen any of theſe ſorts of Grapes perfectly well. The fires ſhould not be made very ſtrong in theſe walls, for if the air is heated to about ten degrees above the temperate point on the botanical thermometers, it will be ſufficiently warm to force out the ſhoots leiſurely, which is much better than to force them violently. Theſe fires ſhould not be continued all the day time, unleſs the weather ſhould prove very cold, and the ſun does not ſhine to warm the air, at which times it will be proper to have ſmall fires continued all the day; for where the walls are rightly contrived, a moderate fire made every evening, and continued till ten or eleven of the clock at night, will heat the wall, and warm the incloſed air to a proper temperature; and as theſe fires need not be continued longer than about the end of april (unleſs the ſpring ſhould prove very cold,) the expenſe of fuel will not be very great, becauſe they may be contrived to burn coal, wood, turf, or almoſt any other ſort of fuel; though where coal is to be had reaſonable, it makes the eveneſt and beſt fires, and will not require ſo much attendance. When the Vines begin to ſhoot, they muſt be frequently looked over to faſten the new ſhoots to the trellis, and rub off all dangling ſhoots; in doing of which great care muſt be taken, for the ſhoots of theſe forced Vines are very tender, and very ſubject to break when any violence is offered. The ſhoots ſhould alſo be trained very regular, ſo as to lie as near as poſſible to the eſpalier, and at equal diſtances, that they may equally enjoy the benefit of the air and ſun, which is abſolutely neceſſary for the improvement of the fruit. When the Grapes are formed, the ſhoots ſhould be ſtopped at the ſecond joint beyond the fruit, that the nouriſhment may not be drawn away from the fruit in uſeleſs ſhoots, which muſt be avoided as much as poſſible in theſe forced Vines; upon which no uſeleſs wood ſhould be left, which will ſhade the fruit, and exclude the air from it by their leaves.

As the ſeaſon advances and the weather becomes warm, there ſhould be a proportionable ſhare of free air admitted to the Vines every day, which is abſolutely neceſſary to promote the growth of the fruit; but the glaſſes ſhould be ſhut cloſe every night, unleſs in very hot weather, otherwiſe the cold dews in the night will retard it. The bunches of the White Frontinac ſhould alſo be carefully looked over, and the ſmall Grapes cut out with very narrow-pointed ſciſſars, in order to thin them, for theſe berries grow ſo cloſe together on the bunches, that the moiſture is detained between them, which often occaſions their rotting; and the air being excluded from the middle of the bunches, the Grapes never ripen equally, which by this method may be remedied, if done in time; and as theſe Grapes are protected by the glaſſes from the blights which frequently take thoſe which are expoſed, there will be no hazard in thinning theſe Grapes ſoon after they are ſet, at which time it will be much eaſier to perform this operation, than when the Grapes are grown larger, and conſequently will be cloſer together; but in doing this the bunches muſt not be roughly handled, for if the Grapes are the leaſt bruiſed, or the bloom which there naturally is upon them, be rubbed off, their ſkins will harden, and turn of a brown colour, ſo that the fruit will never thrive after; therefore the ſciſſars which are uſed for this purpoſe, ſhould have very narrow points, that they may be more eaſily put between the Grapes without injuring the remaining ones. The other ſorts of Grapes which I have recommended for theſe hot walls, not producing their fruit ſo cloſe together on the bunches they will not require this operation, unleſs by any accident they ſhould receive a blight, which often occaſions a great inequality in the ſize of the Grapes; which, whenever it thus happens, will require to be remedied by cutting off the ſmall Grapes, that the bunches may ripen equally, and appear more ſightly.

By the middle of june theſe Grapes will be almoſt full grown, therefore the glaſſes may be kept off continually in the day time, unleſs the ſeaſon ſhould prove very cold and wet, in which caſe they muſt be kept on, and only opened when the weather is favourable; for as the racy vinous flavour of theſe fruits is increaſed by a free air, ſo during the time of their ripening, they ſhould have as large a ſhare as the ſeaſon will admit to be given them.

Before the Grapes begin to ripen, they muſt be carefully guarded againſt birds, waſps, and other inſects, otherwiſe they will be deſtroyed in a ſhort time: to prevent which, the Vines ſhould be carefully covered with nets ſo as to exclude the birds, who make great havock with the Grapes, by breaking their ſkins; and if there are a few twigs covered with birdlime placed here and there on the outſide of the nets, it will be of ſervice, becauſe the birds are often ſo bold as to attempt to break the nets to get to the Grapes; which, if they attempt, they may be ſo entangled on theſe twigs, as not to get looſe; and whenever that happens, they ſhould not be diſengaged, but ſuffered to remain to keep off their companions; and if they get off themſelves, it will have the deſired effect, for there will few other birds come to the ſame place that ſeaſon, as I have more than once experienced.

As to the waſps, the beſt method is to hang up ſome phials about half filled with ſugared water, and rub the necks of the phials with a little honey, which will draw all the waſps and flies to them, which, by attempting to get at the liquor, will fall into the phials and be drowned; theſe phials ſhould be carefully looked over once in three or four days to take out the waſps and deſtroy them, and to repleniſh the phials with liquor. If this be duly obſerved, and the phials placed in time, before the Grapes are attacked, it will effectually prevent their being injured; but where theſe precautions are not taken, the Grapes will be in danger of being abſolutely deſtroyed; for as theſe early Grapes will ripen long before any others againſt common walls, they will be in much more danger, there being no other fruit for them at that ſeaſon in the neighbourhood; whereas when Grapes in general begin to ripen, there is a quantity in almoſt every garden; ſo that if they deſtroy a part in each garden, yet there will be a greater chance to have ſome eſcape, than where there is only one wall for them to attack.

Theſe ſorts of Grapes being forced in the manner before directed, will begin to ripen early in auguſt, eſpecially the Black and Red Frontinacs, which will be fit for the table a fortnight earlier than the other ſorts; but as the deſign of forcing them is to have them in as great perfection as poſſible in this climate, they ſhould not be gathered until they are thorough ripe, for which reaſon ſome of the later ſorts ſhould be left on the Vines till ſeptember; but then the glaſſes ſhould be kept over them in wet and cold weather to protect the fruit from it, but whenever the weather is fair, the glaſſes muſt be opened to let in the free air, otherwiſe the damps, ariſing from the earth at that ſeaſon, will cauſe a mouldineſs upon the Grapes, which will rot them; ſo that if the ſeaſon ſhould prove very cold and wet while the fruit is upon the Vines, it will be proper to make a ſmall fire every night to dry off the damps, and prevent this injury. Moſt people in England gather their Grapes too ſoon, never ſuffering them to remain on the Vines to ripen perfectly, even in the warmeſt ſeaſons, when, if they are left on till after Michaelmas, they will be good.

[*Directions for the management of Vines in the Hot-houſe or Pine Stove.*

Having a Hot-houſe built according to the inſtruc-

tions

tions given under the article STOVES: and having taken the proper precautions to lay it dry by drains, and by a floor of chippings of ſtone, coarſe gravel, broken bricks or lime rubbiſh, eight or ten inches thick, over which a thin layer of fine loam may be well puddled to fill up the chinks, if neceſſary, on account of having a retentive clay ſoil or a barren ſand; and having given the whole a fall of ſix or eight inches; unleſs the ſoil ſhould happen to be a rich ſandy loam, fill up the area with a compoſt-mould compoſed of one fourth ſtrong loam; one fourth turf from a paſture where the ſoil is a ſandy loam, one fourth ſweepings or ſcrapings of pavements or hard roads, one eighth rotten cow and ſtable-yard dung mixed, and one eighth of vegetable mould from decayed oak leaves: the graſs muſt be well rotted, and the whole worked together till it is uniformly mixed. Where ſandy loam cannot be had, common ſand may be uſed; and the mould of rotten ſticks, or old woods, or from hollow trees, may be ſubſtituted for decayed leaves.

This border being prepared, if the weather will permit, the Vines may be planted at the end of february or the beginning of march, in front of the Hot-houſe; having firſt taken the precaution to put a little moſs round the upper part of each ſtem, with two or three folds of paper over it, tied with baſs matting; to prevent the eyes from being injured in putting the plants through the holes in the wall.

Oppoſite to each rafter, and cloſe to the front wall, make a hole two feet over, and one foot deep; make the mould taken out of the holes fine, and add a little of the compoſt. Turn the plant carefully out of its pot, and put the upper part through the hole. If the ſhoot will juſt reach the bottom of the rafter, when planted, it will be ſufficient, but as the earth may ſettle a little, it is better to allow two or three inches for this circumſtance. In cloſing the mould to the plant care ſhould be taken to preſerve the roots, their fibres being exceedingly brittle. Lay a thin coat of rotten dung over the mould, and give the plant a gentle watering: then take off the bandage, and faſten the top of the ſhoot to the rafter.

Only one ſhoot ſhould remain on each plant. Two may be left for a time, but when one is ſecure, the other muſt be taken off, but not cloſe to the old wood, as that would occaſion it to bleed.

From the time the Vines begin to grow, they will require conſtant watering, eſpecially in dry weather, and before the roots have penetrated deep into the border.

Train a ſhoot up to each rafter, and if the rafters be not a ſufficient depth to keep the leaves of the Vines from touching the glaſs, fix iron pins of about nine inches in length, at proper diſtances under each rafter; theſe ſhould have a ſmall hole or eye at the bottom, through which a ſmall iron rod or ſtrong wire ſhould be thruſt, for the ſupport of the branch. The pins and wires muſt be painted.

The Vine-plants will frequently ſhow fruit at one year old, but this ſhould not be ſuffered to ſtand, except a ſingle bunch, if wanted to aſcertain the ſort.

During the ſummer, water the roots conſtantly; keep them regularly faſtened to the rafters; diveſt them of their wires and lateral ſhoots; and above all, guard them againſt the depredations of the red ſpider and other inſects.

The Vines may be permitted to run two-thirds of the length of the rafters, twenty or twenty-five feet, before they are ſtopped: and thoſe which grow remarkably ſtrong, may be ſuffered to run the whole length of the rafters, or about thirty feet.

After theſe ſhoots are ſtopped, which is done by pinching off their tops, they will, in general, puſh out laterals, at three or four eyes on the upper part of the ſhoot; it will be prudent to permit theſe to grow twelve or fourteen inches before their tops are pinched off. Theſe in their turn, will puſh out ſecondary laterals, which ſhould be pinched off at the ſecond or third joint; and thus the ſap may be diverted till the end of the ſeaſon.

November and the beginning of december, when the leaves begin to fall, is the beſt ſeaſon for pruning. The firſt ſeaſon, ſuppoſing the Vines to have grown with equal vigour, the ſhoots may be pruned alternately to three, four or five eyes, and to about twenty-one or twenty-two feet. But if they have grown moderately ſtrong, the ſhoots ſhould be pruned down to about eleven feet.

By this alternate pruning, the former ſhoots will make fine wood for the ſucceeding ſeaſon, and the latter will produce a crop of fruit; after which, theſe fruit-bearing ſhoots muſt all be cut down nearly to the bottom of the rafters. But when any of the plants appear weak, and have not made ſhoots more than eight, ten, or twelve feet long, it will be proper to prune every ſhoot down to two, three or four eyes.

In pruning, take off the ſhoots, with a clean ſloping ſtroke, about half an inch above the eye. Make choice of a bold eye to terminate the ſhoot, and faſten it completely to the rafter.

Vines in pine-ſtoves begin to make weak ſhoots early in january; the houſe being then kept warm on account of early crops raiſed in moſt hot-houſes. But when it is kept to a proper degree of heat for pines during the winter months, the Vines will ſeldom begin to puſh till about the middle of february. It is uſual to ſee them puſh only towards the ends of the ſhoots, the other eyes remaining in a dormant ſtate, and cauſing a long ſpace of naked wood. To make the eyes puſh more generally, as ſoon as the ſap is in motion, keep the houſe, for a ſhort time, a few degrees warmer than uſual. In the morning the thermometer ſhould be 5° or 6° above temperate, and in the day-time the houſe ſhould be kept as warm as the weather will permit. It will alſo be neceſſary to guard the ſtem of the Vine on the outſide againſt froſt; for one ſevere night would greatly injure, if not totally deſtroy, the hopes of a crop. This may be done, by wrapping the part expoſed round with moſs, faſtened thick with baſs matting. Leave this covering on till ſpring froſts are over, and then waſh the ſtem well to clean it.

When Vines break out freely, they puſh at almoſt every eye, nearly at the ſame time. It is eaſy to diſtinguiſh which will make the moſt promiſing ſhoots even as ſoon as the eyes begin to break; and by the time they are three or four inches long, the bunches are very diſtinguiſhable. The Vines ſhould be diveſted of the leaſt promiſing and ſupernumerary ſhoots as ſoon as poſſible, as it will greatly contribute to invigorate the remainder.

Caution ſhould be obſerved not to leave too abundant a crop; for few bunches in a high ſtate of perfection, are preferable to many in a leſs. Therefore in caſe the ſhoots which are pruned to about twenty-two feet, ſhould ſhow two or three bunches at almoſt every eye, as they will frequently do, no more ſhould be permitted to ſtand than the leading ſhoot, and four or five on each ſide; and the remaining ſhoots ſhould have only one bunch left on each, which ſhould be the beſt proportioned and moſt regularly formed. The ſhoots ſhould be left four or five feet apart on each ſide, and one ſhoot as near the bottom as it can be got. Train them regularly on each ſide of the rafter, and pinch off the top of each as ſoon as it begins to interfere with the adjoining ſhoot above; or in general, let the ſhoots be ſtopped at the ſecond or third joint above the bunch.

During the time of flowering, ſhould the weather prove hot and dry, with briſk winds, the berries of many kinds of Grapes, particularly the blue Frontenac, white Sweetwater, and black Damaſcus, are liable to fall off at the time of their ſetting, and the remainder are in general ſmall and without ſtones. This proceeds from the calyx adhering to and drying upon the germ, and thereby preventing its impregnation. It is proper therefore at this period to water the roots of the Vines plentifully, to keep the houſe as cloſe as the weather will permit, and to water the walks and flues in the hot-houſe conſtantly, eſpecially late in the evening, when the glaſſes ſhould be immediately cloſed. The heat of the houſe will exhale the moiſture, and raiſe a kind of artificial dew, which, by falling upon the calyx, will cauſe it to expand and fall off. But although Grapes ſet beſt in a cloſe moiſt air, yet the houſe ſhould not be violently hot during the time of their ſetting.

Digitized by Google

When the weather is ſerene, tranſparent drops of dew will be obſervable in a morning on the points of the leaves. This is the moſt favourable indication that can happen at the ſeaſon of the Vine's flowering: for the Grapes ſet well, and the growth of the berries is extremely rapid, when the Vines are in this ſtate.

Pull off all ſuperfluous ſhoots, and diveſt the young ſhoots of all their laterals, during the ſummer. Do this without reſerve, becauſe every ſhoot left more than twenty feet long at the laſt year's pruning, with intent to produce a crop of fruit, muſt be cut down nearly to the bottom at the next winter's pruning.

But all the reſt of the Vines that were cut down at the laſt year's pruning, ſuppoſe one at every alternate rafter, muſt be trained with one ſhoot each, exactly the ſame in every reſpect as in the preceding ſeaſon.

When Grapes are at their laſt ſwelling, are becoming tranſparent, and change from green to red or black, and till they are nearly on the point of being ripe, the Vines will require a plentiful ſupply of water, eſpecially if the ſeaſon prove hot and dry. The ſituation of Vines in a pine-ſtove may be conſidered as ſimilar to that of very hot climates, where they cannot have Vineyards without a command of water.

After the fruit is cut, the Vines will not require any other management till the pruning ſeaſon, but taking off their lateral ſhoots in the ſame manner as in the preceding year.

At the next winter's pruning all the Vines that produced a full crop of fruit, ſhould be cut down nearly to the bottom, that is to the lowermoſt ſummer ſhoot, which ſhould alſo be cut down to the firſt or ſecond eye.

But all thoſe Vines that were cut down nearly to the bottom the preceding ſeaſon, and which will, in general, have made very ſtrong wood, muſt be left to the length of twenty-one or twenty-two feet each, with intent to produce a full crop of fruit the following ſeaſon.

The management of the Vines during the next ſummer, will be nearly the ſame as in the preceding one: only as they have increaſed in ſtrength and ſize, they will be enabled to produce and ſupport a larger burden of fruit.

The crop ſhould, at all times, be proportioned to the ſize and vigour of the Vine: but eſpecially whilſt Vines are young, great moderation ſhould be uſed as to the number of bunches that are allowed to ripen.

The ſhoots may now be laid rather cloſer than in the preceding ſeaſon, and two bunches may remain on ſtrong and vigorous ſhoots, eſpecially of thoſe kinds which do not produce large bunches. The bunches ſhould be well thinned when the berries are about the ſize of a ſmall ſhot. The main ſhoulders, as alſo the leſs projecting parts of the bunch, ſhould be ſuſpended by ſmall ſtrings to the rafters, and every part raiſed to an horizontal poſition. In thinning the berries, great care ſhould be taken to leave all the moſt projecting ones on every ſide of the bunch. In very cloſe-growing bunches, it will be neceſſary to clip out more than two-thirds of the berries; in ſome, one half; but in the looſe-growing kinds, one third is generally ſufficient. Thus the remaining berries will ſwell well, grow to a great ſize, and not be ſubject to rot; as they are apt to do in a hot-houſe, when they are wedged together.

Not only the rafters or roof of the hot-houſe, but the back wall alſo above the flue, may be furniſhed with fruit.

For this purpoſe, let every fourth or fifth Vine-plant be trained in one ſhoot quite to the top of the rafter, and then directed ſideways ten or twelve feet along the top of the back wall. At the winter's pruning, bring down that part of the ſhoot perpendicularly, and cut it off at one foot above the top of the flue. The next ſpring, encourage only two ſhoots from the two extreme or lowermoſt eyes of each ſhoot ſo brought down, and train them in an horizontal direction one foot above the top of the flue. Theſe ſhoots however will grow with greater readineſs, if they are trained upwards during the ſummer; and they may eaſily be brought to the deſired poſition at the next winter's pruning. They will then form againſt the back wall the figure of the letter T inverted.

In the next ſeaſon the horizontal ſhoots will produce new wood from almoſt every eye, provided all the ſhoots be pinched off from every other part as ſoon as they appear. Lay in the ſhoots from one to two feet apart, according to the kind of Vine.

Train all the ſhoots in a perpendicular direction, and provided they are ſtrong, and vigorous, ſuffer them to grow to the length of five or ſix feet before they are ſtopped; but all theſe ſhoots muſt be cut down to two or three eyes at the next winter's pruning.

Only one ſhoot ſhould be permitted to riſe from each ſpur the following ſeaſon; and although they will in general be ſufficiently ſtrong, and produce two or three bunches a piece, yet only one bunch ſhould remain on each ſhoot: theſe will then be large and fine, and the wood will be greatly benefited by ſuch practice.

Theſe ſhoots muſt be pruned next winter very differently. One ſhoot muſt be left four feet, that next it only a few inches long, and ſo alternately.

The Vines on the rafters will require a management in future ſeaſons nearly ſimilar to that already deſcribed for them; and although it will not be adviſable to prune them alternately ſo near to the bottom of the rafters as was directed for the two preceding ſeaſons, yet it will be frequently found neceſſary to cut an old ſhoot down to the lowermoſt ſummer ſhoot, as near to the bottom of the rafter as can be. The ſide ſhoot, on the other rafters, ſhould not be permitted to ramble over the adjoining lights; but at the end of every ſeaſon it will be proper to cut ſuch ſhoots down to the ſecond or third eye next the old wood, provided the bottom eyes are bold and ſtrong; this muſt be done not only to ſtrengthen the Vines, but alſo to prevent the roof of the houſe from being too much crowded with old wood.

Whilſt the Vines are young, one rafter will ſuffice for a Vine-plant; but when they become older, they will require a larger ſpace; eſpecially the ſtrong growing kinds, which produce large leaves and bunches. It will be proper therefore to train ſhoots ſideways on the wall-plate, from the ſtem of the plant, immediately at its entrance into the houſe. Theſe ſhoots ſhould be carried up the adjoining rafters, and the plants growing againſt ſuch rafters muſt be taken entirely away; except it ſhould happen that the plant growing againſt ſuch rafter is trained forward to furniſh the back wall.

When a Vine-plant occupies two or more rafters, it will be right to prune occaſionally, particularly whilſt the Vine is young, one or more of ſuch ſhoots down nearly to the bottom of the rafter. This will not only contribute to ſtrengthen the plant, but will afford means to furniſh the rafters with a ſucceſſion of young wood.

When Vine-ſhoots are thus conducted to different rafters, every ſhoot may be conſidered as a ſeparate plant, and muſt be trained up in one ſhoot: from that time it will require a management ſimilar to that already laid down[m].

On the Propagation of Vines.

Beſides the two common modes of propagating the Vine, which are treated of by Mr. Miller, by layers and cuttings; they may alſo be increaſed by ſeeds, by grafting, and by inoculation.

In raiſing Vines from ſeed, it ſhould be ſown at the end of february or beginning of march, in pots filled with light freſh mould, and plunged in a moderate hot-bed, gently ſprinkling the mould from a watering-pot having a fine roſe. Six or eight ſeeds, if gathered from ripe Grapes and carefully preſerved through the winter, will be ſufficient for a ſmall pot, for if ſown too thick, the plants are apt to be drawn and weak. In dry weather water the pots gently every day; but in wet or moiſt weather give them ſo much water only as will keep the mould moiſt till the plants begin to vegetate. Let this be done in the afternoon, when the ſun is going off the frame; which ſhould be ſhut down immediately, and if the heat be not too great, it may remain ſhut during the night. As the heat of the bed decays, add a lining of horſe-dung, to be ſhaken up and repaired,

[m] Speechly, p. 24. and p. 71 to 95.

as

Digitized by Google

as occaſion requires, till the plants have got ſufficient ſtrength to do without any bottom heat.

About the end of auguſt take the lights off, that the plants may be hardened before winter, taking care to ſhelter them in frames covered with mats, which will prevent the autumnal froſts from injuring the tender ſhoots.

When the plants are about ſix inches high, tranſplant them ſingly into other pots (deep forty-eights), filled with light freſh mould, taking great care not to hurt the roots, or to break the leaders; then plunge them again into the hot-bed; or if the heat of the old bed be too much decayed, have a new one prepared to receive them. If they grow vigorouſly, they muſt be ſhifted into larger pots (thirty-twos.)

If the plants are above ſix inches high, tie them to ſmall rods, as high as the frames will permit, leaving only one ſtem for the firſt year.

When the leaves begin to drop, pick them carefully off the pots, to prevent the plants from becoming mouldy.

Keep the plants under frames, or in the greenhouſe, in hard winters, to ſhelter them from ſevere froſt. In march or the beginning of april, if from ſeed ripened in this country, plant them out where they are to remain; but if from foreign ſeed, plant only one or two, till it has been aſcertained that they are worth cultivating.

After they are planted, cut them at the third eye, if ſtrong; but at the ſecond, if weakly: at the ſame time rubbing off the lower bud with the finger and thumb [n].

Mr. Speechly recommends the Grapes deſigned for ſeed to remain on the Vine till they are perfectly ripe, when the ſtones are generally of a very dark-brown colour; to take them from the pulp, and to lay them on a ſheet of paper, in ſome airy, but ſhady place to dry, till ſpring.

The intention of raiſing Vines from ſeed being to procure new varieties of Grapes, ſuperior to the old ones; Mr. Speechly recommends, that in the hot-houſe, where a variety of the beſt Grapes is trained, the young branches of two different kinds ſhould be ſo brought together, as ſoon as they ſhow their fruit, that their bunches, in the ſame ſtate of maturity, may admit of being entwined. Attention ſhould be paid to the ſize, the flavour, and the delicacy of the ſkin and fleſh; alſo to the form of the bunch, and the length of the foot-ſtalk.

He remarks that all the Frontinac Grapes are proper to add flavour to other kinds; that the White Muſcat of Alexandria is a good one to be joined with many other ſorts, on account of its large looſe-growing bunches, and large well-flavoured berries; that the White Sweetwater may be coupled with various ſorts that are ſmall and leſs delicate; particularly with the Red Frontinac; the Syrian with the White Muſcat of Alexandria; the Black Hamburgh with the White Frontinac or Sweetwater; the Black Damaſcus with the Grizzly Frontinac; Flame-coloured Tokay with Red Frontinac; White Muſcat of Alexandria with White Sweetwater; Black Frontinac with White Muſcadine; St. Peter's Grape with White Muſcat of Alexandria. Hence he augurs, that the beſt ſorts of Grapes hitherto known, will at ſome future day, be eſteemed only as ſecondary or inferior [o].

This theory may be fanciful, and we cannot ſay any thing deciſive upon it till it has been tried; Mr. Speechly having merely thrown it out to ſtimulate perſons of taſte and curioſity.

It is probable however that many of the preſent varieties of Grapes have been obtained from ſeed, either ſown by hand, or accidentally let fall by birds, &c. And it is undoubtedly the chief, if not the only way to obtain new kinds with us. If therefore it be little practiſed, it is partly on account of the diſtant proſpect of fruit, partly from the hazard of obtaining better kinds than we have already. To this it may be anſwered, that a ſeedling Vine, judiciouſly managed, will produce fruit the third or fourth year; and if proper care and attention be beſtowed on the ſeed ſown, the beſt ſorts may very reaſonably be expected [p].

[n] Forſyth, p. 113. [o] Page 39 to 44. [p] Idem. p. 38 and 44.

On Grafting of Vines.

At the pruning ſeaſon, make choice of cuttings for grafts, or ſcions, from the beſt bearing branches of the ſorts intended to be propagated. In general the bottom part of the laſt year's ſhoot is to be preferred; but in well-ripened vigorous wood, any part of the ſhoot will anſwer, provided it be not too long-jointed. Theſe cuttings ſhould be preſerved in pots filled with light ſandy earth till the grafting ſeaſon.

Vines in a pine-ſtove ſhould be graſted in the beginning of january; but the middle of march is a proper ſeaſon to graft Vines growing in the open air. In general they ſhould be grafted about three weeks before they begin to break into bud.

Upon ſmall ſtocks, not more than an inch in diameter, cleft-grafting is moſt proper; but upon larger ſtocks, whip-grafting is to be preferred. In both methods care ſhould be taken in fitting the ſtock and ſcion together, and the operation ſhould be performed with great exactneſs. Faſten them together with baſs matting, and cover them with clay in the uſual way.

Though the ſcion will ſometimes begin to puſh in a few weeks, yet it will frequently remain dormant two or three months: during this period the ſtock muſt be ſtripped of all its ſhoots, as ſoon as they appear; and to preſerve the ſcion in a vegetative ſtate, the clay muſt be kept moderately moiſt, by wrapping wet moſs round it, and by keeping the moſs conſtantly ſprinkled with water.

When the ſcion has made ſhoots five or ſix inches long, the clay and bandage ſhould be carefully taken off.

But the moſt eligible method with Vines is grafting by approach. In which caſe it is neceſſary, to have the plant intended to be propagated, in a pot. Strong plants, that have been two or three years in pots, are to be preferred; but plants from the nurſery may be potted, and grafted in the ſame ſeaſon, if brought into a hot-houſe or vinery.

Fine Grapes and good wood may be obtained even the firſt ſeaſon, by any of theſe methods, but particularly by the laſt; in which it is obvious that the graft has a double ſupport; namely, from the ſtock, and from the plant in the pot.

In grafting by approach the clay and bandage ſhould remain two or three months after the graft has formed an union; for if it be taken off ſooner, the graft will be very liable to ſpring from the ſtock. The pot ſhould be plentifully ſupplied with water till the month of auguſt, when the graft ſhould be ſeparated from the plant in the pot. Two or three inches of wood below the bottom of the graft may be left, but ſhould be taken clean off at the next winter's pruning.

The Syrian Vine is the moſt proper for ſtocks, and plants raiſed from ſeeds of this ſort, are greatly preferable to plants raiſed either from layers or cuttings for this purpoſe. If the produce of theſe ſeeds ſhould even degenerate to a kind of wildneſs, they will ſtill be the better for ſtocks, becauſe they will on that account, riſe with greater vigour.

The moſt important advantages of grafting are; firſt, that if a wall ſhould have been planted with bad kinds of Vines; inſtead of ſtubbing them up, and making a new border, by which ſeveral years muſt elapſe before the wall can again be completely filled: by grafting, the nature of the Vines may be changed immediately; for good Grapes may be obtained from the ſame year's graft: and in a hot-houſe the grafts, if permitted, will frequently ſhoot thirty or forty feet the firſt ſummer. Secondly, in ſmall Vineries, or Vine-frames, where any great variety could not be had in the common way; it may be procured by grafting different kinds upon the ſame plant. Thus a Syrian Vine, in the hot-houſe at Welbeck, produces ſixteen different ſorts of Grapes.

But the principal advantage of grafting, is the improvement of the various kinds, and particularly the ſmall ones, which generally make weak wood. This may be done by grafting the weak and delicate-growing Vines upon the ſtocks of thoſe which are more robuſt and vigorous. Thus the ſmall blue Frontinac engrafted on the Syrian Vine, produces well-ſized handſome bunches, with berries almoſt as large as thoſe of the Black Hamburgh [q].

On propagating Vines by Layers.

Mr. Miller has not given any directions upon this ſubject.

Vines may be increaſed by ſtools in open quarters, in the ſame manner as nurſery-men propagate foreſt trees and ſhrubs; but the beſt way is to train ſhoots that will eaſily bend, on walls, at full length during the ſummer, and in february to lay the fineſt and ſtrongeſt acroſs the foot-path into pots (twenty-fours or ſix-teens) filled with freſh mould, and plunged in the ground about two inches below the ſurface; at the ſame time making an inciſion or two in the old wood, or giving it a twiſt juſt below a joint: they will generally take without notching or twiſting, but it is the ſurer way to do it. Introducing the ſhoots through the bottom of the pots is now laid aſide, becauſe when this method is followed, the layers generally have larger roots below the pots than in them. The layers muſt be cut, leaving two or three ſtrong eyes upon each.

When the ſhoots begin to run, tie them to long ſtakes, to prevent their being broken by the wind. Pick off all the runners and ſide ſhoots, leaving only two or three fine ſtrong ſhoots on each plant, which ſhould be trained at full length during the ſummer.

Cover the ſhoots with good dung or rotten leaves, to keep the mould moiſt; and in very dry ſummers give them a good watering once or twice a week.

By this method, there may be two or three rows of layers from one wall; taking care to lay the branches alternately, and to keep the pots plunged about two inches below the level of the ground. The plants will be well rooted in the pots before autumn, and fit for planting in vineries, hot-houſes, &c.

When they are to be planted out, cut them carefully from the mother Vine, and carry them in the pots to the place where they are to be planted; taking care to preſerve the ball of earth about their roots, as much as poſſible, when they are turned out of the pots.

If the ſeaſon be warm and fine, Grapes of early kinds ripen very well on theſe layers before they are taken up; and, if properly managed, they will bear ſome fruit the firſt year after planting. One of the ſtrongeſt ſhoots muſt be left nearly at full length, cutting it as nigh as the uppermoſt full bud, leaving nothing but round well-ripened wood. If there are three ſhoots, the remaining two ſhould be cut ſo as to leave only two full eyes upon each, which ſhould be trained at full length, to produce fine wood for next year. The ſhoot which was trained the preceding year ſhould then be cut down, leaving only two ſtrong eyes to produce wood for the following year; and ſo on every year, cutting the branches alternately. By ſo doing, the walls will be kept always covered with fine healthy bearing wood; and much time will be ſaved in furniſhing hot-houſes and vineries[r].

On propagating Vines by Cuttings.

Mr. Miller has treated largely upon this mode of propagation, and this only: ſome improvements however may be ſuggeſted even here from late experience.

The cuttings ſhould be choſen from thoſe ſhoots which have the ſhorteſt joints, always having one or two joints of the laſt year's wood, cutting it perfectly ſmooth and a little rounding at the lower end, and as near to a joint of the old wood as poſſible. Cut the upper end ſmooth and ſloping towards the wall; or if in beds or borders, let the cut always face the north. Againſt piers or walls, ſet them at about a foot diſtance, and ſo deep as to have the ſecond eye level with the ground; remembering always to rub off the lower eye. Pick off all runners and ſide ſhoots, leaving only two ſhoots, which ſhould be trained at their full length. In january or february they may be pruned, leaving one or two eyes on each, according to the ſtrength of the ſhoot.

In the firſt year, eſpecially if the ſummer be dry, and they have not been duly watered, they will make little progreſs: but in the ſecond year it will be plainly diſcerned which is the ſtrongeſt plant, and that only ſhould be left to fill up the vacant ſpace on the wall. The reſt ſhould be taken up and planted in other ſituations where they are wanted.

Mr. Speechly[s] offers what he thinks a more advantageous method, from only a ſingle eye and about three inches and an half of the laſt year's wood: plants thus raiſed being, as he has experienced, greatly preferable to cuttings raiſed in the common way, as having more abundant roots, growing ſhorter, being more prolific, and coming into bearing the ſecond year. This method firſt occurred to the Rev. Mr. Michell, a profound philoſopher, who has explained the ſubject at length, in a letter to Mr. Speechly, which he has printed as a note.

Make choice of the cuttings after a warm dry ſeaſon. Each ſhould have two inches of the old wood, with one eye of the new. When the Vines are pruned there will be great choice: ſelect ſuch as are of a middling ſize, and have the wood round and perfectly ripened. Cut the bottom part perfectly ſmooth; and if any of the old dead ſnags remain, cut them off cloſe to the quick wood, and cut the top ſloping towards the back of the hot-houſe or frame. Put only one cutting in each pot, which ſhould be a deep forty-eight, filled with rich light mould well prepared. The plants will thus grow much ſtronger and quicker than when many are crowded together, and the ſun and air will have a freer admiſſion to ripen the wood. When the plants begin to get ſtrong, and the pots full of roots; ſhift them into larger pots (thirty-twos.)

This mode is beſt adapted to private gardens. They who raiſe plants for ſale in larger quantities, and cannot conveniently ſpare ſo much room, may plant three or more cuttings in each pot. A method frequently practiſed by nurſerymen and gardeners, who wiſh to have their plants fit for ſale the ſame year, is to ſet them in pots in the hot-houſe, among the tan, on the flues, or round the curbs of the pit. They may be raiſed in this manner, either ſingly in ſmall pots, or ſeveral together in larger ones, tranſplanting them ſingly when they have taken root. In this caſe it will be neceſſary to have a hot-bed ready to plunge the pots in as ſoon as they are tranſplanted. Thus their growth will be forwarded very much, and before autumn they will be fit for ſale[t].

Mr. Michell prefers planting the cuttings in the bark without pots, both becauſe he thinks the pots prevent the heat from being ſo kindly, and that ſo many more cuttings may be planted in the naked bark; four or five inches diſtance being ſufficient, provided they are not ſuffered to grow there too long before they are potted. For cuttings forced in this way he does not think that old wood is either neceſſary or uſeful; a hot-houſe ſummer upon them being fully ſufficient to ripen their wood, if not even almoſt to over-ripen it. This learned gentleman's reaſons for preferring the ſhort cuttings with a ſingle eye are very philoſophical, and are well confirmed by experience[u].

Mr. Speechly recommends forward ſhoots forced early, for cuttings; theſe having a longer ſummer to ripen the wood. He reprobates the choice of ſhoots of uncommon ſize, as abounding too much with pith: and directs an attention to the following particulars: 1. The eye or bud ſhould be large, prominent, and bold. 2. The ſhoots ſhould be moderately ſtrong, round and ſhort-jointed. 3. The texture of the wood ſhould be cloſe, ſolid, and compact. But the beſt criterion is its ſolidity and having very little pith[x].

On the Pruning and Training of Vines.

The wood muſt be ſtrong, or the bunches will be ſmall. If the latter be the caſe, cut the plant down to two or three eyes, in order to have ſtrong wood for next year. If there be much old naked wood on the Vines, with ſome ſmall weak ſhoots at the extremities, cut them down as near the ground as poſſible: you will then have no fruit for that year. Or you may cut every other ſhoot; leaving the old ones to produce ſome ſmall Grapes. The next year, there will be plenty of fine wood, provided the ſtrongeſt ſhoots have

[r] Forſyth, p. 118 to 120.

[s] Page 53. [t] Forſyth, p. 115 to 118. [u] Speechly, p. 55. note. [x] Idem. p. 57.

been

Digitized by Google

been nailed in, and all the ſide ſhoots pinched off, or cut out with a ſharp penknife cloſe to the eye: but never twiſt them, for by twiſting you hurt the bud that is to produce fruit next year: always obſerving to cut as near to a bud as poſſible, and taking care to lay in the wood very thin in ſummer, that the ſun and air may be freely admitted to ripen it. Keep the ſhoots nailed to the wall, to prevent their being broken by high winds; and pick off all the ſide ſhoots every time they are nailed, which ought to be done ſeveral times during the ſummer months, according to the quickneſs of their growth. In fine weather they will require to be looked over once every fortnight or three weeks. Never ſuffer the Vines to run together in a cluſter, and to mat; for that will infallibly ruin them for bearing the ſucceeding year. Top the ſhoots as ſoon as the Grapes come to the ſize of ſmall peas, a joint or two above the fruit; but never top the leading ſhoot, nor that which you intend ſhould bear fruit next year.

In the ſecond year never prune till the beginning of february, except in very forward ſeaſons, owing to a fine autumn and mild winter, after the wood has been well ripened in the preceding ſummer; in which caſe the Vines will be more forward in the middle of january, than in backward ſeaſons at the end of march. It is common to begin pruning ſoon after the fall of the leaf; but if a froſt ſets in before the wood is hard, it will be very much injured. We have often fine weather in october and november, which helps to ripen the wood after wet autumns.

When the leaves begin to fall, take a ſoft broom, and ſweep them off upwards gently; which will aſſiſt in hardening the wood.

In pruning, always make choice of the ſtrongeſt and longeſt ſhoots, leaving them as long as the eyes are good and plump, and the wood round; but by no means leave them when they become flat, for ſuch ſeldom bear fruit; or if they do, it will be very ſmall. Never lay in any that has leſs than from fifteen to thirty good eyes, according to the ſtrength of the ſhoot; which will produce two bunches from every good eye. The ſhoots that have borne fruit in the preceding year ſhould be cut out next year, except when you want to fill the wall, and the ſhoots are very ſtrong. Never leave any but fine ſtrong wood, always cutting at the ſecond, third or fourth eye; rubbing the loweſt bud off, and that which comes out at the joint between the new and the laſt year's wood. By theſe means you will get as much fruit from theſe ſhort ſhoots as you would have by the common way of pruning. Obſerve to leave two or three of the ſtrongeſt ſhoots for next year's bearing wood, and never top them. If there is not room to train them, you may lead them over the tops of the other trees, if the Vines are planted againſt piers; or you may run them behind the ſtandards, and thus cover the whole of the wall. You may alſo run the ſhoots at the bottom of the wall behind the dwarf trees; or you may tack them down over the top of the wall, on the other ſide, provided the walls are low; you may alſo train them over the tops of trees on each ſide; which never does any harm to the trees below, provided they are kept nailed to the wall; they may even be planted on north and eaſt aſpects, and trained over the tops of the ſouth and weſt walls to fill the upper parts, till the Peaches and Nectarines cover them.

Although the foregoing directions are given chiefly for Vines on walls in the open ground, yet the ſame method may be practiſed for forced Grapes.

The following is the method which Mr. Forſyth purſued with ſome Vines which were planted againſt the piers of a ſouth wall, among old peaches, nectarines, &c.

When he took them in hand, the fruit was ſo ſmall and hard as to render it unfit to be ſent to table. The Vines were trained upright, which cauſed them to grow ſo luxuriantly that the ſap flowed into the branches inſtead of the fruit.

He let two ſtrong branches grow to their full length without topping them in the ſummer. The next year he trained theſe in a ſerpentine form, leaving about thirty eyes on each ſhoot, which produced one hundred and twenty fine bunches of Grapes, weighing from one pound to a pound and a quarter each. Next year he trained five plants in the ſame way, allowing the ſhoots intended for bearing wood to run their full length in ſummer, training them wherever there was a vacancy between the old trees; and where there were none, running them along the top of the wall without topping them. In winter he trained them in a ſerpentine manner ſo as to fill the wall as regularly as poſſible: they were as productive as thoſe in the former year.

After at hree year's trial, he followed the ſame practice with the whole; and in the year 1793 ſent, for the uſe of the king and royal family, three hundred and ſeventy-eight baſkets of Grapes, each weighing about three pounds, without planting a ſingle Vine more than there were the preceding year, in which he was able to ſend only fifty-ſix baſkets of the ſame weight, and thoſe ſo bad and ill-ripened, that they were not fit to be ſent to table.

Obſerve to bring the ſhoots as near as poſſible from the bottom of the Vine, that the wall may be well covered. When the walls are high, and the ſhoots from the ſerpentine branches ſtrong, they may ſometimes remain; but if the walls are low, and the ſerpentine branches produce weak ſhoots, they ſhould be cut out in the autumnal pruning, and the ſtrongeſt of the young wood trained up in their room [y].

For the method of pruning and training Vines in ſtoves, ſee Directions for their management in the Hothouſe given above.

On Watering the Vine.

The Vine requires a warm dry ſoil in England, yet in a hot dry ſummer it ſhould have a plentiful ſupply of water, eſpecially in the hot-houſe. In hot countries the Vine is ſaid to grow moſt luxuriant near water, and the alluſions to this circumſtance in Scripture are very frequent. In Madeira, we are told, they do not attempt to plant Vineyards, except where there is a command of water: and in Spain a copious vintage depends upon abundant rains [z].

With reſpect to Vines on walls in the open air, after the Grapes are ſet and begin to ſwell, they may be watered three times a week, if the weather be hot and dry, with the Barrow Engine; ſprinkling them all over the leaves and fruit, preſſing your forefinger over the top of the pipe, to throw the water as fine as ſmall rain. This will keep the Vines clear from duſt and inſects, and promote the ſwelling of the fruit; but it muſt never be done when the nights are cold and froſty. The beſt time for the operation is about four o'clock, in a ſouth aſpect; for the ſun will then be going off the wall, and the leaves will have time to dry before night. In very hot dry weather, a good bottom watering once a week, will forward the ſwelling of the fruit; but when the fruit is fully ſwelled, it ſhould be left off, particularly when the nights begin to be cold, for it would then hurt the flavour of the fruit [a].

With reſpect to Vines in hot-houſes, proviſion being made by drains, &c. as above directed, to keep the border in a dry ſtate during winter; gentle and frequent waterings ſhould be given in ſpring, when the weather is dry.

When the Vines are in flower, even the frequent ſprinkling the flues and walks in a hot-houſe; and the border, &c. in a vinery, will greatly benefit the plants. A good heat however ſhould be kept up, becauſe Grapes ſet beſt in a vapourous heat of between ſeventy and ſeventy-five degrees.

In a hot-houſe, if the walks, &c. are ſprinkled when there is a ſtrong ſun, the exhaled moiſture will inſtantly form a kind of artificial dew, which is exceedingly nouriſhing to Grapes in their infant ſtate.

When ſtrong fires are kept, if the flues are frequently ſprinkled with water, a ſteam will ariſe, which has alſo a good effect. With this view, contrivances have been made to introduce hot ſteam into ſtoves.

When the Grapes are grown to the ſize of ſmall peas, the Vines will require a conſtant ſupply of water, till they are full grown. If the border be kept in a moderate moiſt ſtate during the above period, the Vines will

[y] Forſyth, p. 123 to 127. [z] Speechly, p. 85, 87, 146.
[a] Forſyth, p. 127.

Digitized by Google

grow luxuriant, and the Grapes will ſwell to a large ſize. But when the Grapes are nearly ripe, the waterings ſhould be leſs frequent, as too much water at that ſeaſon would tend to debaſe their flavour.

When the crop is gathered, the border ſhould be frequently watered, till the leaves of the Vines begin to change. But from that time, and during the winter, the border ſhould be kept in a dry ſtate.

It does not ſeem neceſſary to water the leaves of Vines growing in the ſtove, except they ſhould be infected with inſects. But during a mild rain, the upper lights may be let down, that the Vines on the back wall may reap the benefit of it.

During winter, the Vine-border may be watered with the drainage of dunghills; but this ſhould only be applied when the roots are in a ſtate of inaction [b].

On the Preſervatian of Vines and Grapes.

Although the Vine is not very liable to be infeſted with inſects, when growing in the open air; yet few plants ſuffer more from their ravages than when trained under glaſs, eſpecially in Pine-ſtoves: the conſtant warmth kept up in theſe houſes during winter ſerving to keep up the ſucceſſion of them from one ſeaſon to another.

A ſpecies of Acarus, commonly called the Red Spider, is the moſt pernicious; theſe inſects frequently attack the leaves of the Vine early in the ſummer, and their increaſe in dry weather being very quick and great, they will ſoon greatly damage, and in time totally deſtroy the foliage. They generally reſide and breed on the under ſide of the leaves; and when they are very numerous they work a fine web all over it, and round the edges. The upper ſurface appears full of very ſmall dots or ſpots of a light colour.

The Red ſpider however does not confine itſelf to the leaves, but attacks the bunches of Grapes alſo, eſpecially when they are almoſt ripe; and as they extract the juice from them, the Grapes ſoon become ſoft, flabby and ill-flavoured.

The Thrips, an hemipterous inſect, ſometimes attacks the young ſhoots of Vines growing in the open air, eſpecially thoſe which are weak or newly planted. If young ſhoots are injured by late ſpring froſts, the tender part of the leaf will curl up, and change to a dark-brown colour: in this ſtate the Thrips attacks them with great greedineſs, eſpecially the White Sweetwater and Muſcadine. This inſect however is ſeldom injurious to Vines growing in the open air, except in the ſpring: to thoſe in the hot-houſe they are moſt hurtful when the Grapes are nearly ripe; they attack the bunches as well as the leaves, and commonly prey upon the extremities of the berries, particularly that next the footſtalk. In white Grapes, the part injured changes to a dark colour, the footſtalk turns black, and the berry withers.

Aphides or Plant-lice ſometimes infeſt the young ſhoots of Vines, but as they grow very rapidly, theſe inſects do not often greatly injure them.

Two or three ſpecies of Cocci ſometimes infeſt the Vine, as Coccus heſperidum and adonidum. The latter is ſometimes miſtaken for the crimſon tinged Pine-bug. Theſe abound in hot-houſes and conſervatories, and breed upon the Coffee Tree, Oleander, &c. but they are not very prejudicial to the Vine.

All theſe inſects, the Acarus excepted, may be deſtroyed by a ſtrong fumigation of tobacco. For the method of doing this, ſee the article STOVES.

It would be improper to fumigate late in the ſpring, or in the ſummer, becauſe the ſmoke would injure the Grapes, by giving them a diſagreeable flavour. Where inſects have been numerous the preceding ſeaſon, they muſt be deſtroyed effectually before the Vines come into flower; this may be done by fumigating two or three different times, at the diſtance of three or four days between each operation. Pine-ſtoves are much more liable to be infeſted with theſe inſects, than Grape-houſes or Vineries, becauſe in theſe it is uſual to take off the glaſs-frames during the winter, by which the inſects generally periſh, but the warmth of the pine-

[b] Speechly, p. 146 to 152.

ſtove protects them through the winter. In theſe too, the Thrips is often greatly encouraged by the vegetables cultivated there, particularly by kidney-beans. In order therefore to prevent the increaſe of theſe inſects, which is very rapid, after the ſtove has been fumigated, remove all the kidney-bean plants, and then ſow a freſh crop of them immediately, placing the pots all over the flues, &c. that in caſe any inſects ſhould have eſcaped the fumigation, the young kidney-bean plants may attract them: as ſoon as theſe plants appear to be infected, take them away and ſow a freſh crop.

The Red Spider may be deſtroyed by a compoſition of one pound of flowers of ſulphur, and two ounces of common ſcotch ſnuff or very good tobacco duſt, well mixed together. Take a ſmall bruſh, ſuch as is uſed for common painting, dip it lightly in the compoſition, then lay one hand on the upper ſurface of the leaf, and with the other draw the bruſh very gently backwards and forwards all over the under ſurface. The Acarus being ſoft and delicate, is hereby deſtroyed with the moſt gentle touch; the bruſh alſo readily wipes off their web, as well as their globular tranſparent eggs, which are faſtened by a fine membrane to the leaves; and thus we are ſecured from the danger of a ſucceeding brood.

This proceſs may ſeem tedious; but it is eaſily performed upon Vines trained in a regular manner, and a ſingle operation is generally ſufficient for a whole ſeaſon. This ſhould be performed as ſoon as the inſects make their appearance. Sulphur alone is ſufficient for the purpoſe, but the ſnuff or tobacco duſt renders the mixture equally fatal to the Thrips alſo [c].

Mr. Forſyth aſſerts, that the beſt thing to deſtroy the Red Spider and other inſects is moiſture. Frequent watering of trees with lime-water, and throwing it plentifully on the under ſide of the leaves, will in a ſhort time extirpate the Red Spider.

In hot-houſes, he recommends uſing water only, in the following manner. Between three and four in the afternoon, fill the barrow-engine with ſoft water, wheel it along the paths of the houſe, where they are wide enough to admit it, and ſprinkle all the plants; play alſo in a fine ſhower againſt the top lights and ſhelves, till the water ſtands an inch deep in the paths. If you cannot conveniently get the barrow-engine into the houſe, and have not Philips's ſmall copper engine, or ſome other of the like ſort; open the front lights, or ſlide down the top lights, and throw water in from thence. When this operation is performed within, every light muſt be ſhut; when from without, keep one light only open at a time; the houſe muſt be then kept cloſe ſhut till next morning: this will cauſe ſuch an exhalation from the glaſs, tan, &c. that the plants will be covered with the vapour, which will infallibly deſtroy the Cocci, Aphides, and other inſects: but the watering muſt be repeated every afternoon, during hot weather only. Before morning the plants will have imbibed all the moiſture, and the paths will be perfectly dry.

To protect Grapes, as they ripen, from birds, in the open air, they muſt be bagged; or, where the bunches hang very thick, the Vines may be covered with nets, or buntine, which is the ſtuff of which ſhips' colours are made; theſe will admit the air freely to the Grapes; and will ſoon dry after rain. They are alſo the beſt covering in the ſpring, in cold, wet or ſnowy weather.

For Waſps and the large Fleſh Fly or Blue-bottle as it is vulgarly called, there is no other remedy but hanging plenty of bottles with ſome ſweet liquor in them upon the Vines. The Fly comes firſt, and is no leſs deſtructive to the fruit than the Waſp. The bottles ſhould be hung up as ſoon as the former make their appearance; and ſhould be emptied frequently. When the weather is very hot and the Waſps are numerous, they will frequently be ſo intent upon the fruit as not to enter faſt enough into the bottles: if you then take a little oil in a cup and with a feather dipped in it touch their backs, they will inſtantly drop down. Great numbers may eaſily be deſtroyed this way: and ſo might

[c] Speechly, p. 160 to 168.

the

Digitized by Google

the flies, if their motions were not ſo quick that it is difficult to touch them.

The bunches of Grapes ſhould be kept under the ſhade of the leaves till they begin to ripen; then thoſe which cover the fruit may be picked off, leaving ſuch as are a little above it to be a ſhelter from the wet and froſt in the nights: this will aſſiſt in ripening the fruit; and take off only a few leaves at a time, according to the quantity of Grapes to be gathered at once: by theſe means the fruit will continue three times as long in ſucceſſion, as it would if the leaves were picked off all at once. If all the leaves ſhould be taken off ſoon after the fruit is ſet, the fruit will not ſwell, but become hard and ſmall, and generally crack. When the leaves are not too thick, they admit the rays of the ſun to paſs through, and a warm glow of heat will be reflected from the wall.

Grapes will often hang on the Vines till the middle of november, if they are well covered with nets or buntine: but when the froſt begins to ſet in ſharp they ſhould be gathered. Where ſeveral bunches are on one branch, it may be cut off, leaving ſix inches in length, or more, of the wood, according to the diſtance between the bunches, and a little on the outſide of the fruit at each end: ſeal both ends with common ſealing-wax; then hang them acroſs a line in a dry room, taking care to clip out any berries that begin to decay or grow mouldy. In this way Grapes may be kept till february; or, if they are cut before the bunches are very ripe, they may be kept much longer. They may alſo be preſerved in jars; each bunch being wrapped in ſoft paper, and layers of bran, well dried, being laid between them. Put ſome bran at the bottom and top; ſhake the whole gently; put ſome paper over it, and cover the jar with a bladder firmly tied on to exclude the air. Keep the jar in a dry room, or where you can have a fire in wet or damp weather [d].

With reſpect to the tranſporting or carriage of Grapes, when they are to be conveyed by water, they may be packed in boxes or jars with ſand. They are thus brought from Portugal. But ſand is too heavy for land carriage, and the Grapes muſt then be waſhed before they can be eaten. They may alſo be packed with any ſmall bright ſeed. Clover-ſeed is very proper for this purpoſe; but this alſo is heavy, and too valuable to be waſted. Some pack them in tow, wool, cotton or paper-ſhavings. Mr. Speechly recommends oat-chaff as moſt eligible, both on account of its lightneſs and its elaſticity. Care ſhould be taken that it have not any diſagreeable ſmell, and that it be cleanſed of all impure matter: the Grapes ſhould be perfectly dry, and the branches well examined, that if there be any decayed, cracked or bruiſed berries, they may be clipped off: each bunch ſhould then be tied in a bag of ſilver or gauze paper. Grapes packed in this manner, ought not to be more than two courſes in depth, otherwiſe the lower bunches would be liable to ſuffer injury by the weight above. The courſe of chaff between the layers of fruit, and likewiſe at the top and bottom, ought, when it is well preſſed down, to occupy a ſpace of two or three inches.

When Grapes are to travel by a ſtage coach, the boxes ſhould be made to ſuit the ſeats of the coach; for unleſs they go within or on the top, they will commonly be ſpoiled [e].]

Of Vineyards in England.

There have of late years been but very few Vineyards in England, though it appears by ancient records that they were formerly very common, as may be gathered from the ſeveral places in divers parts of England, which yet retain that name, which teſtify the quantities of ground which were allotted for Vineyards, to abbies and monaſteries, for wine for the uſe of the inhabitants; but as to the quality of the wines which were then produced in England, we are at preſent ignorant; and how theſe Vineyards were rooted up, and became ſo generally neglected, we have no very good accounts left. Whatever might be the cauſe of this total neglect in cultivating Vines in England, I will not pretend to determine, but ſuch was the prejudice moſt people conceived to any attempts of producing wine in England, that for ſome ages paſt, every trial of that kind has been ridiculed by the generality of people, and at this day very few perſons will believe it poſſible to be effected.

The firſt and great things to be conſidered in planting Vineyards is the choice of ſoil and ſituation, which, if not rightly choſen, there will be little hopes of ſucceſs, for upon this the whole affair greatly depends. The beſt ſoil for a Vineyard in England is ſuch, whoſe ſurface is a light ſandy loam, and not above a foot and a half or two feet deep, above the gravel or chalk, either of which bottoms are equally good for Vines; but if the ſoil is deep, or the bottom either clay, or ſtrong loam, it is by no means proper for this purpoſe; for although the Vines may ſhoot vigorouſly, and produce a great quantity of Grapes, yet theſe will be later ripe, fuller of moiſture, and ſo conſequently their juice not mature, nor well digeſted, but will abound with crudity, which in fermenting will render the wine ſour and ill-taſted, which is the common complaint of thoſe who have made wine in England.

Nor is a very rich, light, deep ſoil, ſuch as is commonly found near London, proper for this purpoſe; becauſe the roots of the Vines will be enticed down too deep to receive the influences of ſun and air, and hereby will take in much crude nourihment, whereby the fruit will be rendered leſs valuable, and be later ripe, which is of ill conſequence to theſe fruits, which are known to imbibe a great ſhare of their nouriſhment from the air, which if replete with moiſture (as is commonly the caſe in autumn,) muſt neceſſarily contribute greatly to render the juices leſs perfect, therefore great attention ſhould be had to the nature of the ſoil upon which they are planted.

The next thing neceſſary to be conſidered, is the ſituation of the place, which if poſſible, ſhould be on the north ſide of a river, upon an elevation inclining to the ſouth, with a ſmall gradual deſcent, that the moiſture may the better drain off, but if the ground ſlopes too much, it is by no means proper for this purpoſe; but if, at a diſtance from this place, there are larger hills, which defend it from the north and north-weſt wind, it will be of great ſervice, becauſe hereby the ſun's rays will be reflected with a greater force, and the cold winds being kept off, will render the ſituation very warm. Add to this a chalky ſurface; which if thoſe hills do abound with (as there are many ſuch ſituations in England,) it will ſtill add to the heat of the place, by reflecting a greater quantity of the ſun's rays.

The country about this ſhould be open and hilly, for if it be much planted, or low and boggy, the air will conſtantly be filled with moiſt particles, occaſioned by the plentiful perſpiration of the trees, or the exhalations from the adjoining marſhes, whereby the fruit will be greatly prejudiced (as was before obſerved.) Theſe Vineyards ſhould always be open to the eaſt, that the morning ſun may come on them to dry off the moiſture of the night early, which, by lying too long upon the Vines, greatly retards the ripening of their fruit, and renders it crude and ill taſted. And ſince the fruit of Vines is rarely ever injured by eaſterly winds, there will be no reaſon to apprehend any danger from ſuch a ſituation, the ſouth-weſt, north-weſt, and north winds being the moſt injurious to Vineyards in England (as indeed they are to moſt other fruit,) ſo that, if poſſible, they ſhould be ſheltered therefrom.

Having made choice of a ſoil and ſituation proper for this purpoſe, the next thing to be done is, to prepare it for planting. In doing of which the following method ſhould be obſerved: in the ſpring it ſhould be ploughed as deep as the ſurface will admit, turning the ſward into the bottom of each furrow; after this it ſhould be well harrowed, to break the clods, and cleanſe it from the roots of noxious weeds, and it muſt be often ploughed and harrowed for at leaſt one year, to render the ſurface light; and hereby it will be ren-

[d] Forſyth, p. 128, 258, 278. [e] Speechly, p. 88. note.

Digitized by Google

V I T

dered fertile, by imbibing the nitrous particles of the air (eſpecially if it be long expoſed thereto before it is planted;) then in march the ground ſhould be well ploughed again, and after having made the ſurface pretty even, the rows ſhould be marked out from ſouth-eaſt to north-weſt, at the diſtance of ten feet from each other; and theſe rows ſhould be croſſed again at five or ſix feet diſtance, which will mark out the exact places where each plant ſhould be placed; ſo that the Vines will be ten feet row from row, and five or ſix feet aſunder in the rows, nearer than which they ought never to be planted. And herein moſt people who have planted Vineyards have greatly erred, ſome having allowed no more than five feet row from row, and the plants but three feet aſunder in the rows; and others, who think they have been full liberal in this article, have only planted their Vines at ſix feet diſtance every way, but neither of theſe have allowed a proper diſtance to them, as I ſhall ſhew: for in the firſt place, where the rows are placed too cloſe, there will not be room for the ſun and air to paſs in between them to dry up the moiſture, which, being detained amongſt the Vines, muſt produce very ill effects: and, ſecondly, where the Vines are placed in exact ſquares, ſo near together as ſix feet, there can be no room for the current of air to paſs between them, when their branches are extended on each ſide, and ſo conſequently the damps in autumn will be entangled and detained amongſt the Vines, to the great prejudice of their fruit; for ſince the autumns in England are often attended with rains, cold dews, or fogs, all proper care ſhould be taken to remove every thing which may obſtruct the drying up the damps which ariſe from the ground.

The ſkilful vignerons abroad are alſo ſenſible how much it contributes to the goodneſs of their Vines, to allow a large ſpace between the rows; and therefore where the quality of the wine is more regarded than the quantity, there they never plant their Vines at leſs than ten feet row from row, and ſome allow twelve. It was an obſervation of Bellonius, almoſt two hundred years ſince, that in thoſe iſlands of the Archipelago, where the rows of Vines were placed at a great diſtance, the wine was much preferable to thoſe which were cloſe planted; and this he poſitively affirms to be the caſe, in moſt countries where he had travelled. Indeed we need not have recourſe to antiquity for the certainty of ſuch facts, when we are daily convinced of this truth in all cloſe plantations of any kind of fruit, where it is conſtantly obſerved, that the fruits in ſuch places are never ſo well coloured, ſo early ripe, nor near ſo well flavoured, as thoſe produced on trees, where the air can freely circulate about them, and the rays of the ſun have free acceſs to the branches, whereby the juices are better prepared before they enter the fruit.

Having thus conſidered the diſtance which is neceſſary to be allowed to theſe plants, we come next to the planting; but in order to this, the proper ſorts of Grapes ſhould be judiciouſly choſen; and in this particular we have egregiouſly erred in England. All the Vineyards at preſent planted here, are of the ſweeteſt and beſt ſort of Grapes for eating, which is contrary to the general practice of the vignerons abroad, who always obſerve, that ſuch Grapes never make good wine; and therefore, from experience, make choice of thoſe ſorts of Grapes, whoſe juice, after fermenting, affords a noble rich liquor; which Grapes are always obſerved to be auſtere, and not by any means palatable. This is alſo agreeable to the conſtant practice of our cyder-makers in England, who always obſerve, that the beſt eating apples make but poor cyder; whereas the more rough and auſtere ſorts, after being preſſed and fermented, afford a ſtrong vinous liquor. And I believe it will be found true in all fruits, that where the natural heat of the ſun ripens and prepares their juices ſo as to render them palatable, whatever degree of heat theſe juices have more, either by fermentation, or from any other cauſe, will render them weaker and leſs ſpirituous. Of this we have many inſtances in fruits; for if we tranſplant any of our ſummer or autumn fruits, which ripen perfectly in England, without the aſſiſtance of art, into a climate a few degrees warmer, theſe fruits will be meally and inſipid; ſo likewiſe if we bake or ſtew any of theſe fruits, they will be good for little, loſing all their ſpirit and flavour by the additional heat of the fire; and ſuch fruits as are by no means eatable raw, are hereby rendered exquiſite, which, if tranſplanted into a warmer climate, have, by the additional heat of the ſun, been alſo altered ſo as to exceed the moſt delicious of our fruit in this country.

From whence it is plain, that thoſe Grapes which are agreeable to the palate for eating, are not proper for wine; in making of which, their juices muſt undergo a ſtrong fermentation; therefore ſince we have in England been only propagating the moſt palatable Grapes for eating, and neglect the other ſorts; before we plant Vineyards, we ſhould take care to be provided with the proper ſorts from abroad, which ſhould be choſen according to the ſort of wines intended to be imitated; though I believe the moſt probable ſort to ſucceed in England is the Auvernat, or true Burgundy Grape, (which is at preſent very rare to be found in the Engliſh Vineyards, though it is a common Grape in the gardens againſt walls.) This ſort of Grape is moſt preferred in Burgundy, Champaign, Orleans, and moſt of the other wine countries in France; and I am informed, that it ſucceeds very well in ſeveral places to the north of Paris, where proper care is taken of their management; ſo that I ſhould adviſe ſuch perſons as would try the ſucceſs of Vineyards in England, to procure cuttings of this Grape from thoſe countries; but herein ſome perſon of integrity and judgment ſhould be employed, to get them from ſuch Vineyards where no other ſorts of Grapes are cultivated; which is very rare to find, unleſs ſome particular Vineyards of the citizens, who are very exact to keep up the reputation of their wines, nothing being more common than for the vignerons to plant three or four ſorts of Grapes in the ſame Vineyard, and at the time of Vintage to mix them all together: which renders their wines leſs delicate, than in ſuch places where they have only this one ſort of Grape. And here I would caution every one againſt mixing the juice of ſeveral Grapes together, which will cauſe the wine to ferment at different times, and in different manners.

The cuttings being thus provided (for I would always prefer theſe to layers, or rooted plants, for the reaſons given at the beginning of the article Vitis) about the beginning of April is the beſt ſeaſon for planting, when it will be proper to put the lower ends of the cuttings in water about three inches, ſetting them upright for ſix or eight hours before they are uſed; then at the center of every croſs mark already made by a line, to the diſtance the Vines are deſigned, ſhould be a hole made with a ſpade, or other inſtrument, about a foot deep, into each of which ſhould be put one ſtrong cutting, placing it a little ſloping; then the hole ſhould be filled up with earth, preſſing it gently with the feet to the cutting, and raiſing a little hill to each about three inches, ſo as juſt to cover the uppermoſt eye or bud, which will prevent the wind and ſun from drying any part of the cuttings, and this upper eye only will ſhoot; the under ones moſt of them will puſh out roots, ſo that this ſhoot will be very ſtrong and vigorous.

After they are thus planted, they will require no other care until they ſhoot, except to keep the ground clear from weeds, which ſhould be conſtantly obſerved; but as the diſtance between the rows of Vines is very great, ſo the ground between them may be ſown or planted with any kind of eſculent plants, which do not grow tall, provided there is proper diſtance left from the Vines, and care taken that the Vines are not injured by the crops, or in the gathering, and carrying them off the ground; and this huſbandry may be continued three or four years, till the Vines come to bearing; after which time, there ſhould be no ſort of crop put between them in ſummer, becauſe the cleaner the ground is kept between the Vines from weeds or plants, the more heat will be

Digitized by Google

be reflected to the Grapes; but after the Grapes are gathered there may be a crop of Coleworts for ſpring uſe planted between the rows of Vines, and the cultivating of theſe will be of uſe to the Vines, by ſtirring of the ground; but as to watering, or any other trouble, there will be no occaſion for it, notwithſtanding what ſome people have directed, for in England there is no danger of their miſcarrying by drought. When the cuttings begin to ſhoot, there ſhould be a ſmall ſtick of about three feet long ſtuck down by each, to which the ſhoot ſhould be faſtened, to prevent their breaking or lying on the ground; ſo that as the ſhoots advance, the faſtening ſhould be renewed, and all ſmall lateral ſhoots (if there are any ſuch produced) ſhould be conſtantly diſplaced, and the ground between the Vines always kept clean. This is the whole management which is required the firſt ſummer.

But at michaelmas, when the Vines have done ſhooting, they ſhould be pruned; for if they are left unpruned till ſpring, their ſhoots being tender (eſpecially towards their upper parts) will be in danger of ſuffering if the winter ſhould prove ſevere.

This pruning is only to cut down the ſhoots to two eyes; and if, after this is done, the earth be drawn up in a hill about each plant, it will ſtill be a greater defence againſt froſt.

At the beginning of march the ground between the Vines ſhould be well dug to looſen it, and render it clean; but you ſhould be careful not to dig deep cloſe to the Vines, leſt thereby their roots ſhould be cut or bruiſed, and at the ſame time the earth ſhould be again laid up in a hill about each plant; but there muſt be care taken, not to bury the two young eyes of the former year's ſhoot which were left to produce new wood.

At the beginning of may, when the Vines are ſhooting there ſhould be two ſtakes fixed down to the ſide of each plant, which muſt be ſomewhat taller and ſtronger than thoſe of the former year; to theſe the two ſhoots (if ſo many are produced) ſhould be faſtened, and all the ſmall trailing or lateral ſhoots ſhould be conſtantly diſplaced, that the other ſhoots may be ſtronger, and the ground ſhould alſo be kept very clear from weeds as before.

The autumn following theſe Vines ſhould be pruned again in the following manner; thoſe of them which have produced two ſtrong ſhoots of equal vigour, muſt be cut down to three eyes each; but in ſuch as have one ſtrong ſhoot and a weak one, the ſtrong one muſt be ſhortened to three eyes, and the weak one to two; and ſuch Vines as have produced but one ſtrong ſhoot, ſhould be ſhortened down to two eyes alſo in order to obtain more wood againſt the ſucceeding year.

In the ſpring, about the beginning of march, the ground between the Vines ſhould again be dug, as before, and two ſtakes ſhould be placed down by the ſide of all ſuch Vines as have two ſhoots, at ſuch diſtance on each ſide of the plant as the ſhoots will admit to be faſtened thereto, and the ſhoots ſhould be drawn out on each ſide to the ſtakes, ſo as to make an angle of about forty-five degrees with the ſtem; but by no means ſhould they be bent down horizontally, as is by ſome practiſed, for the branches lying too near the earth, are generally injured by the damps which ariſe from thence, but eſpecially when they have fruit, which is never ſo well taſted, nor ſo early ripe upon thoſe branches, as when they are a little more elevated.

In may, when the Vines begin to ſhoot, they muſt be carefully looked over, and all the weak dangling ſhoots ſhould be rubbed off as they are produced, and thoſe ſhoots which are produced from ſtrong eyes, ſhould be faſtened to the ſtakes to prevent their being broken off by the wind.

This management ſhould be repeated at leaſt every three weeks, from the beginning of may to the end of july; by which means the ſhoots which are trained up for the ſucceeding year will not only be ſtronger, but alſo better ripened and prepared for bearing, becauſe they will have the advantage of ſun and air, which is abſolutely neceſſary to prepare their juices; whereas if they are crouded by a number of ſmall dangling weak branches, they will ſhade and exclude the rays of the ſun from the other ſhoots; and ſo by detaining the moiſture a longer time amongſt the branches, occaſion the veſſels of the young wood to be of a larger dimenſion; and hereby the crude juice finds an eaſy paſſage through them; ſo that the ſhoots in autumn ſeem to be moſtly pith, and are of a greeniſh immature nature, and wherever this is obſerved, it is a ſure ſign of a bad quality in the Vines. The ſoil alſo ſhould be conſtantly kept clean, becauſe if there are any vegetables (either weeds or plants of other kinds) growing between the Vines, it will detain the dews longer, and by their perſpiration, occaſion a greater moiſture than would be, if the ground were entirely clear; ſo that thoſe who plant other things between their rows of Vines, are guilty of a great error.

In autumn the Vines ſhould be pruned, which ſeaſon I approve of rather than the ſpring (for reaſons before given;) and this being the third year from planting, the Vines will now be ſtrong enough to produce fruit, therefore they muſt be pruned accordingly. Now ſuppoſe the two ſhoots of the former year, which were ſhortened to three eyes, have each of them produced two ſtrong branches the ſummer paſt, then the uppermoſt of theſe ſhoots upon each branch ſhould be ſhortened down to three good eyes (never including the lower eye, which is ſituate juſt above the former year's wood, which ſeldom produces any thing, except a weak dangling ſhoot;) and the lower ſhoots ſhould be ſhortened down to two good eyes each, theſe being deſigned to produce vigorous ſhoots for the ſucceeding year, and the former are deſigned to bear fruit; but where the Vines are weak, and have not produced more than two or three ſhoots the laſt ſeaſon, there ſhould be but one of them left with three eyes for bearing; the other muſt be ſhortened down to two, or if weak one good eye, in order to obtain ſtrong ſhoots the following ſummer; for there is nothing more injurious to Vines, than the leaving too much wood upon them, eſpecially while they are young; or the overbearing them, which will weaken them ſo much, as not be recovered again to a good ſtate in ſeveral years, though they ſhould be managed with all poſſible ſkill.

In march, the ground between the Vines ſhould be well dug as before, obſerving not to injure their roots by digging too deep near them; but where there are ſmall horizontal roots produced on or near the ſurface of the ground, they ſhould be pruned off cloſe to the places where they were produced; theſe being what the vignerons call day roots, and are by no means neceſſary to be left on: and after having dug the ground, the ſtakes ſhould be placed down in the following manner: on each ſide of the Vine ſhould be a ſtake put in at about ſixteen inches from the foot, to which the two branches, which were pruned to three eyes, each for bearing, ſhould be faſtened, (obſerving, as was before directed, not to draw them down too horizontally;) then another taller ſtake ſhould be placed down near the foot of the Vine, to which the two ſhoots which were pruned down to two eyes, ſhould be faſtened, provided they are long enough for that purpoſe; but if not, when their eyes begin to ſhoot, theſe muſt be trained upright to the ſtakes, to prevent their trailing on the ground, hanging over the fruit branches, or being broken by the wind.

In may, the Vines ſhould be carefully looked over again, at which time all weak lateral branches ſhould be rubbed off as they are produced; and thoſe ſhoots which ſhew fruit, muſt be faſtened with baſs to the ſtakes to prevent their being broken, until they are extended to three joints beyond the fruit, when they ſhould be ſtopped; but the ſhoots which are deſigned for bearing the following ſeaſon, ſhould be trained upright to the middle ſtake, by which method the fruit branches will not ſhade theſe middle ſhoots, nor will the middle ſhoots ſhade the fruit, ſo that each will enjoy the benefit of ſun and air.

Digitized by Google

This method ſhould be repeated every fortnight or three weeks, from the beginning of may to the middle of july, which will always keep the ſhoots in their right poſition, whereby the leaves will not be inverted, which greatly retards the growth of the fruit; and by keeping the Vines conſtantly clear from horizontal ſhoots, the fruit will not be crouded with leaves and ſhaded, but will have conſtantly the advantage of the ſun and air equally, which is of great conſequence; for where the fruit is covered with theſe dangling ſhoots in the ſpring, and is afterwards expoſed to the air, either by diveſting it of the leaves, or elſe diſplacing the branches entirely, as is often practiſed, the fruit will become hard, and remain at a perfect ſtand for three weeks, and ſometimes will never advance afterward, as I have ſeveral times obſerved; therefore there cannot be too much care taken to keep it conſtantly in a kindly ſtate of growth, as the vignerons abroad well know, though in England it is little regarded by the generality of gardeners, who when their Grapes ſuffer by this neglect, immediately complain of the climate or the untowardneſs of the ſeaſon, which is too often a cover for neglects of this nature. And here I cannot help taking notice of the abſurd practice of thoſe who pull off the leaves from their Vines, which are placed near the fruit, in order to let in the rays of the ſun to ripen them; not conſidering how much they expoſe their fruit to the cold dews, which fall plentifully in autumn, which, being imbibed by the fruit, greatly retard it; beſides no fruit will ripen ſo well when entirely expoſed to the ſun, as when gently ſcreened with leaves; and by the pulling off theſe leaves, which are abſolutely neceſſary to prepare the juices before they enter the fruit, the groſs parts of which are perſpired away by the leaves, the fruit muſt either be deprived of nouriſhment, or elſe ſome of the groſs particles will enter with the more refined parts of the juice, and thereby render the fruit worſe than it would otherwiſe be, were the leaves permitted to remain upon the branches; for if the weak dangling ſhoots are conſtantly diſplaced as they are produced, the fruit will not be too much ſhaded by the leaves that are upon the bearing branches.

When the fruit is ripe, if the ſtalks of the bunches are cut half through a fortnight before they are gathered, it will cauſe the juice to be much better, becauſe there will not be near ſo great a quantity of nouriſhment enter the fruit, whereby the watery particles will have time to evaporate, and the juice will be better digeſted. This is practiſed by ſome of the moſt curious vignerons in the ſouth of France, where they make excellent wine. But if after the fruit be cut, it is hung up in a dry room upon ſtrings, ſo that the bunches do not touch each other, for a month before they are preſſed, it will alſo add greatly to the ſtrength of the wine, becauſe in that time a great quantity of the watery parts of the juices will evaporate. This is a conſtant practice with ſome perſons who inhabit the Tyroleſe, on the borders of Italy, where is made a moſt delicious rich wine, as hath been atteſted by Dr. Burnet in his travels; and I have heard the ſame from ſeveral gentlemen who have travelled that road ſince. But with all the care that can poſſibly be taken, either in the culture of the Vines, or in making the wine, it will not be near ſo good while the Vineyard is young, as it will be after it has been planted ten or twelve years; and it will be conſtantly mending, until it is fifty years old, as is atteſted by ſeveral curious perſons abroad, as alſo by the moſt ſkilful wine-coopers at home, who can tell the produce of a young Vineyard from that of an old one, after it is brought to England by the colour of the wine. This difference is very eaſily accounted for from the different ſtructure of the veſſels of the plants; thoſe of the young Vines being larger, and of a looſer texture, eaſily admit a larger quantity of groſs nouriſhment to paſs through them; whereas thoſe of old Vines, which are more woody, are more cloſely conſtricted, and thereby the juice is better ſtrained in paſſing through them, which muſt conſequently render it much better, though the Grapes from a young Vineyard will be larger, and afford a greater quantity of juice; ſo that

people ſhould not be diſcouraged if their wines at firſt are not ſo good as they could wiſh, ſince afterward, when the Vineyard is a few years older, the wine may anſwer their expectation.

The Vineyard being now arrived to a bearing ſtate, ſhould be treated after the following manner: firſt, in the pruning there ſhould never be too many branches left upon a root, nor thoſe too long; for although by doing this, there may be a greater quantity of fruit produced, yet the juice of theſe will never be ſo good as when there is a moderate quantity which will be better nouriſhed, and the roots of the plants not ſo much weakened; which is found to be of ſo bad conſequence to Vineyards, that when gentlemen abroad let out Vineyards to vignerons, there is always a clauſe inſerted in their leaſes to direct how many ſhoots ſhall be left upon each Vine, and the number of eyes to which the branches muſt be ſhortened; becauſe were not the vignerons thus tied down, they would overbear the Vines, ſo that in a few years they would exhauſt their roots, and render them ſo weak as not to be recovered again in ſeveral years; and their wine would be ſo bad, as to bring a diſreputation on the Vineyard, to the great loſs of the proprietor.

The number of branches which the Italians generally agree to leave upon a ſtrong Vine are four; two of the ſtrongeſt have four eyes, and the two weaker are ſhortened down to two eyes each.

Conſtantly keep the ground clean between the Vines; dig it carefully every ſpring; and every third year manure it. If the land be ſtiff and inclinable to bind, then lay on ſea-ſand, or ſea-coal aſhes; but if it be looſe and dry; a little lime mixed with dung is the beſt manure. Spread it thin upon the ſurface, and in digging bury it equally in every part. It is much preferable to all dung, and where the Vineyard is large, a third part may be manured every year.

Dig and manure about the beginning of march, at which time all the ſuperficial roots muſt be cut off, but the larger roots muſt not be injured; therefore the ground cloſe to the ſtem of the Vines muſt not be dug very deep. After this is done, place the ſtakes, one on each ſide, at about ſixteen inches from the ſtems, to which the longeſt bearing branches ſhould be faſtened; and one ſtake on each ſide cloſe to the ſtem, to which train the two ſhorter branches upright, to furniſh wood for the ſucceeding year.

In the ſummer look them over carefully, rubbing off all weak dangling ſhoots, and training the good ones to the ſtakes regularly, as they are produced. Stop thoſe which have fruit in june, about three joints beyond the bunches; but the upright ſhoots, which are deſigned for bearing the following year, muſt not be ſtopped till the middle of july, when they may be left about five feet long.

All this ſummer dreſſing ſhould be performed with the thumb and finger, and not with the knife, becauſe wounds made by inſtruments in ſummer do not heal ſo ſoon; and the ſhoots being very tender whilſt young, may eaſily be ſtopped by gently nipping the leading bud.

When a Vineyard is thus carefully dreſſed, the rows regular, the ſtakes exactly placed, and the upright ſhoots ſtopped to an equal height, it makes a beautiful appearance, and when the Vines are in flower, they emit a moſt grateful ſcent, eſpecially in the morning and evening.

But as the beauty of a Vineyard depends upon the regular diſpoſition of the Vine-branches, great care ſhould be taken to train them regularly, and to provide every year for bearing wood; becauſe that which has produced fruit is commonly cut away after the fruit is gathered, or at leaſt is ſhortened down to two eyes, to force out ſhoots for the next year; where there is not a ſufficient number of branches of thoſe trained upright, ſo that in ſummer, when the Vines are in perfection, ſix upright ſhoots ſhould be trained for the next year's wood, and three or four bearing branches with fruit on them: more than theſe ought never to be left on one Vine.

The Auvernat or true Burgundy Grape is valued in France before any other ſort, becauſe the fruit never

Digitized by Google

grows very close upon the bunches, and therefore is more equally ripened; for which reason it should also be preferred in England; for the Grapes in close bunches are commonly ripe on one side, and green on the other, which is a bad quality for such as are to be used in making wine.

[With respect to the practicability of having Vineyards in England, Mr. Speechly remarks, that the vinous latitude extending to the fifty-first degree in the northern hemisphere; that good wines are made in a part of Germany, which is under the same parallel of latitude with our southern counties; and that where the situation and soil are proper for Vines, the lands cannot possibly be more beneficially employed than by being converted into Vineyards.

He recommends an elevated situation, where there is a gentle declivity to the south or south-east, well sheltered from the north, north-west and north-east.

Plantations of forest trees would contribute much to give warmth and shelter; but they must not be too near, so as to confine the air.

Not only gentle declivities, but all slopes on the sides of calcareous hills and mountains are proper for Vineyards, provided they have a southern aspect; which is the case with the rocks on the south coast of England.

As to the soil, the Vine delights in such gravelly and rocky lime-stone soils as are frequently found on the sides of such steep hills and mountains, and will even flourish among mere stones, and the ruins of old walls. Indeed the soil can hardly be too dry in our climate for Vines.

Hence the introduction of Vineyards into this country ought not to have any bad effect on Agriculture, because all strong deep lands best adapted to tillage, are the most unsuitable to Vines; which will prosper in situations and soils, where the lands could hardly be rendered profitable any other way. Though they would not grow robust on steeps of poor gravelly rocky soils; yet they would be more prolific than such as are planted on rich lands, and the fruit would be higher flavoured.

Respecting the sorts of Vines which are best adapted to our climate, Mr. Speechly agrees with Mr. Miller, that the sweet early Grapes are improper for making wine in this country. He recommends those which are cultivated in Germany, particularly that of which rhenish wine is made, in preference to any sort cultivated in France[f].

As to the management of a Vineyard sufficient directions have been already given. Mr. Speechly[g] would have the Vines trained horizontally, similar to the method practised in Holland, with Vines in frames, he thinks they would derive many advantages from this method of training, not only by warmth and shelter, but because they would easily be protected from spring frosts, by applying the boughs of trees, particularly evergreens, and because the Grapes would be greatly benefited by the reflection of the ground.

I am very doubtful of this; and should rather suppose that shading the ground so effectually would be rather injurious to the Grapes in our moist climate.

Most of what Mr. Speechly has delivered on the subject of Vineyards is speculative. The Hon. Charles Hamilton made a fair experiment at Pain's Hall. The Vineyard there was on the south side of a gentle hill; the soil a gravelly sand. It was planted entirely with two sorts of Burgundy Grapes, the Auvernat and the Black Cluster. The first year he attempted to make red wine in the usual way, but it was very harsh and austere; the second he succeeded better in making a white wine, which nearly resembled Champaign in flavour; in two or three years, as the Vines grew stronger, the wine had a finer flavour than the best Champaign. He sold it to wine-merchants for fifty guineas a hogshead; and one wine-merchant to whom he sold five hundred pound's worth at one time, assured him, that he sold some of the best of it from seven shillings and six-pence to ten shillings and sixpence the bottle

After many years experience he let the Grapes hang till perfectly ripe; they were then carefully cut off with sciffors, and brought home in small quantities, to prevent their heating or pressing one another; then they were picked off the stalks, and all the mouldy and green ones were thrown aside, before the Grapes were put into the press; which was done in a few hours after they were gathered. As fast as the juice ran from the press, it was put into hogsheads, and closely bunged up. These were left all winter in the cool barn. When the fermentation was over, it was racked off into clean hogsheads, and carried to the vaults, before any warm weather could raise a second fermentation. In march if any of the hogsheads were not quite fine, they were fined down with fish-glue. All were bottled at the end of march. In about six weeks the wine would be in perfect order for drinking, and be in prime for above one year. The second year the flavour and sweetness abated, and gradually declined till they failed entirely. Some that was kept sixteen years became very like old Hock. The only art ever used was putting three pounds of white sugar-candy to some of the hogsheads, when the wine was first tunned from the press, in conformity to a rage that then prevailed for very sweet Champaign.

Mr. Hamilton on this experience declares himself convinced, that much good wine might be made in many parts of the south of England; many soils and situations being fitter for a Vineyard than his, which was much exposed to the south-west winds, and on a declivity rather too sharp. He allows that the uncertainty of our climate is much against Vineyards, and that many fine crops have been spoiled by may frosts and wet summers: but that one good year balances many disappointments.

Sir Edward Barry, who handed this account to the public, remarks that the prospect of some success, even from the first trials, seems almost certain, if conducted by the rules given by Mr. Hamilton and Miller, with the necessary assistance of a good vigneron; and that it is not improbable that in time Vineyards may be planted, for the profit arising from them, and this country supplied with native wines, very superior to many of those which are now imported[h].

This prophecy has not yet been fulfilled, and there seems little probability that Vineyards should ever become a general article of cultivation in England. The difficulties and discouragements are great and various; those arising from the uncertainty of the climate, and the nicety requisite in the management of the wine, are obvious. Vineyards newly planted cannot be expected to yield a racy juice, and the English are in general of a temper too impatient to wait many years for a rich high-flavoured wine. In the mean time the expense of culture and management will be considerable, and the profit perhaps trifling; so that a large capital will be required for a speculation which may ultimately turn out to be disadvantageous. For even supposing a wine of good quality to be at length produced; unless it should have that sort of flavour which suits fashionable palates, like Claret, Burgundy, and Champaign; or is adapted to the taste of the million, like Port wine, the sale of it will never be so great as to answer an extensive cultivation.]

3. The third sort being a native of warm countries, will not live in England without artificial heat; it is easily propagated by seeds, when they are brought from the countries where the plants grow naturally, for they do not produce any here; these must be sown in small pots, which should be plunged into a hot-bed of tanner's bark. When the plants come up and are fit to remove, they should be each transplanted into a separate small pot filled with light earth, and plunged into a fresh hot-bed of tanner's bark, shading them from the sun till they have taken new root; then they must be treated in the same way as other tender exotic plants from the same countries, always continuing them in the stove, otherwise they will not thrive.

thrive. Theſe plants caſt off their leaves every winter.

5. 6. The fifth and ſixth ſorts grow in great plenty in the woods of America, where I have been informed, are many other ſorts, which produce fruit very little inferior to ſome of the fine ſorts which are cultivated in Europe; notwithſtanding which, it is generally thought impoſſible to make wine in America: this I dare ſay, muſt proceed from a want of ſkill, rather than any bad quality in the ſoil or climate; ſo that inſtead of planting Vineyards on their looſe rich lands (as hath been generally practiſed by the inhabitants of theſe countries) if they would plant them upon riſing ground, where the bottom was rocky or hard near the ſurface, I dare ſay they would have very good ſucceſs; for the great fault complained of in thoſe countries is, that the Grapes generally burſt before they are fully ripe, which muſt certainly be occaſioned by their having too much nouriſhment; therefore, when they are planted on a poorer ſoil, this will be in part remedied. Another cauſe of this may proceed from the moiſture of the air, (occaſioned by the perſpiration of trees, &c.) which being imbibed by the fruit, may break their ſkins. This indeed cannot be prevented, until the country is better cleared of the timber: but however, this ſhould caution people not to plant Vines in ſuch places where there are great quantities of wood, becauſe of this effect, which it hath on the Grapes. But to return:

Theſe two Vines are preſerved in the gardens of thoſe who are curious in botany, but I have not ſeen either of them produce fruit in this country. They may be propagated by layers in the ſame manner as the common Grapes, which will take root in one year, and may be taken off, and tranſplanted in the ſpring where they are to remain, which ſhould be againſt a warm wall; becauſe if they are expoſed to much cold in winter they are often deſtroyed, eſpecially while they are young.

Their pruning and management is the ſame with any other ſorts of Grapes, but only they ſhould have fewer ſhoots, and thoſe ſhortened down very low; indeed the Fox Grape does not like much cutting; otherwiſe it will make very weak ſhoots the following year, and never arrive to any conſiderable ſtrength, ſo will not be capable of producing any fruit.

8. The eighth ſort is planted againſt walls, and treated in the ſame way as the common Vines, and may be propagated by cuttings or layers in like manner.

12. The twelfth ſort is preſerved in ſome gardens for the ſake of variety, but it rarely produces flowers in England, and has not much beauty; it is a native in Virginia and Carolina, from both which countries I have received the ſeeds. As this ſort does not produce ſeeds here, it is generally propagated by laying down the young branches, which will put out roots in one year fit to remove, when they may be taken off, and tranſplanted where they are to remain. Theſe require ſupport; and as their young branches are tender, and liable to be killed by froſt, if they are planted againſt a wall or pale, expoſed to the ſouth, they will ſucceed much better than when they are fully expoſed to the open air, and ſupported by props. The young ſhoots of theſe plants ſhould be ſhortened down to two or three buds in the ſpring, which will cauſe the ſhoots of the following ſummer to be much ſtronger, and when they are regularly trained againſt the wall or pale, they will produce flowers in warm ſeaſons.

This plant is very apt to puſh out ſuckers from the root, by which it is often propagated, but the plants ſo raiſed are very ſubject to ſend out ſuckers again, whereby they are robbed of their nouriſhment, and do not thrive ſo well as thoſe which come from layers.

DESCRIPTION, *&c.*

This is a tree, with round, ſmooth branches, compreſſed a little at the tip. Leaves alternate, a hand and more in length, elliptic, obtuſe, quite entire, ſmooth on both ſides, veined, ſtiffiſh, on a ſhort petiole which is flattiſh above, but convex underneath. Stipules none. Peduncles lateral or a little below the top of the branch, ſolitary or ſometimes two together, compreſſed a little. Pedicels umbelled, ſhort, one-flowered [i]. Fruit a corky or woody nut, compreſſed like a lens, or concavo-convex, or ſnail-ſhaped, in the middle diſtinctly varicoſe with prominent veſſels, but ſmooth towards the periphery, and gradually narrowing to an edge: the upper rim ſtraightiſh, thick with a longitudinal groove and an oblong tubercle below the tip; the lower rim remarkably bowed, quite entire, compreſſed to an edge: the ſurface ſmooth and ſomewhat ſhining; the colour dun or yellow bay. Seed yellow or ruſſet-cinnamon, faſtened to a thick tubercle in the upper part of the cell: coat ſimple, coriaceous, thickiſh; albumen none: radicle placed behind the baſe of the cotyledons.

Size of the nut various, bigger than the palm of the hand, or ſcarcely an inch in diameter, and from a narrow beginning widening gradually into the ſhape of a fly's wing; but always ſomewhat concave and ſnail-ſhaped. Gærtner conjectures, that the fruit, when complete, is compoſed of two nuts, horizontally oppoſite; and that it belongs to the order of Contortæ [k].

It differs entirely from Heretiera. Native of the Eaſt Indies, where it was found by Koenig [l].]

ULEX. *(The name of a ſhrub in Pliny, the aſhes of which were uſed as a lye in ſeparating gold from the ſubſtances with which it was mixed. Martinius derives it ab uligine; but if it be our Furze, or any thing like it, we ſhould rather derive it from* ουλος, *criſpus, contortus.)*

DESCRIPTIONS, *&c.*

[1. This ſhrub, ſo well known in England, has its branches very cloſe, deeply furrowed, woolly or hirſute, full of thorns, which are ſtretched out, branched, angular, very ſharp, ſmooth, evergreen, leafy, frequently flower-bearing; according to Withering, awl-ſhaped, a little bowed downwards, woolly at the baſe, yellow at the ends. Leaves at the baſe of the ſpines and ſpinules, ſolitary, awl-ſhaped, terminating in ſharp yellowiſh thorny points, ſomewhat rugged, often hirſute, deciduous. Peduncles axillary, ſingle or two together, one-flowered, villoſe. Bractes two, approximating to the calyx, looſe, not preſſed cloſe, ſometimes ſpreading, ovate, concave, tomentoſe, five times ſhorter than the calyx or thereabouts. Calyx pale green, ſomewhat ruſty, tomentoſe; teeth ſmall, obtuſe, converging. Corolla half as long again as the calyx, bright-yellow or gold-coloured, having the ſmell of honey ſo ſtrong as to ſcent the whole air, when the flowers are in full vigour. Withering remarks, that the ſtandard and wings are fleſhy at the baſe, the latter ſet with hairs along the lower edge, and curiouſly wrinkled along the upper; petals of the keel united by an intertexture of woolly hairs. Filaments all united in one, (which contradicts the character given by Linneus) with the tube cloven above. Legume oblong, pubeſcent[m], about half an inch long, ſwelling a little, valves very ſmooth within, without any hollows or partitions. Seeds eight or ten, (I never obſerved more than four or five,) reniform-triangular, turgidly lens-ſhaped, ſmooth and ſomewhat ſhining, ruſſet or greeniſh, with a very prominent navel[n].

Native of Britain, Denmark, Brabant, France, Portugal and ſome parts of Germany, on dry gravelly and ſandy heaths and commons. Dr. Smith ſays it is more abundant in Portugal and the weſtern parts of France than any other country except our own. Withering ſays, it does not flouriſh in very poor ſoil: certainly it is never found in ſtrong or wet ſoils. In Cornwall it is extremely luxuriant, growing to the height of ſix or eight feet. I have frequently obſerved it as high in woods, and where it has been ſown thick in incloſures. It begins to flower in may, and continues during a great part of the year. Withering ſays from february to auguſt; and Dr. Stokes, that he obſerved it to be out of flower on the 19th of auguſt. According to Ray, it flowers from may through the whole autumn till winter. This author relates that it is not leſs frequent in Belgium than it is in England; he mentions it as remarkable that he found it in Provence, where it is ſo warm. That ſeems to be its boundary ſouth. Northwards it does not grow in Sweden or Ruſſia; nor is it common in Scotland. Linneus lamented that he could hardly preſerve it alive in a greenhouſe. Many parts of Germany are wholly deſtitute of the Furze-buſh, inſomuch that Dillenius was in a perfect extaſy when he firſt ſaw our commons covered with its golden flowers. And Gerarde relates that about Dantzick, Brunſwick and in Poland, there was not a branch of it growing, except ſome few plants and ſeeds that he ſent, which were moſt curiouſly kept in their faireſt gardens, as alſo our common Broom, which he ſent thither likewiſe, being firſt deſired by divers earneſt letters.

In the ſouth of England it is called Furze; in the eaſtern counties Whins, and in the north Gorſe. In French it is Ajonc or Jonc-marin, contracted to Jomarin.]

Some years ago the ſeeds of Furze were ſown for hedges; and if the ſoil was light, it ſoon became ſtrong enough for a fence againſt cattle; but in a few years theſe hedges became naked at bottom, and ſome of the plants failing, there were gaps in them: of late years therefore they have been little uſed. On very poor hungry gravel or ſandy land this crop has produced more profit than any other, eſpecially where fuel is dear: and it may be uſed in heating ovens, burning lime and bricks, and for drying malt.

[Mr. Evelyn recommends Furze not only for hedges, but for fodder to cattle in winter. Duhamel ſpeaks much in its favour for the latter purpoſe. It has been uſed alſo for fodder in Scotland. The colliers in the foreſt of Dean, chop it ſmall, and give it to their horſes in winter, with great ſucceſs[o]. In Cornwall, where fuel is ſcarce, it is cultivated to advantage, and is generally cut to make faggots for heating ovens, which it does ſoon, burning rapidly and with a great degree of heat. The aſhes are uſed to make ley. Team horſes may be ſupported by this ſhrub, if it is cut young, and bruiſed in a mill to break the thorns. Goats, kine, ſheep and horſes feed upon the tender tops. It is in ſome reſpects a very hardy plant, and will make fences upon the bleakeſt mountains, and cloſe to the ſea ſide, where the ſpray of the ſea deſtroys almoſt every other ſhrub; but it is impatient of cold, and is often deſtroyed, or at leaſt cut down to the roots, by ſevere froſt[p].

2. The dwarf procumbent Furze has been commonly conſidered as a mere variety of the greater upright ſort; even Tournefort and Miller, who erected numberleſs varieties into ſpecies, have not diſtinguiſhed them.] The latter ſays, there are two or three varieties, but they are not worthy to be enumerated: and he affirms that he ſowed their ſeeds in the garden, and found all the varieties ariſe from the ſame ſeeds. [Parkinſon has ſeparated them, and ſays very juſtly, that the leſſer Furze-buſh groweth always lower, with ſmaller and ſhorter thorns; he remarks that the leaves abide much longer before they fall away, which is not until the end of ſpring or beginning of ſummer, ſo that both leaves and flowers are oſtentimes ſeen a good while together; the flowers are ſmaller and of a paler colour; the cods are ſmall and ſhort, without any freeze upon them. Dr. Withering remarks, that the ſeed-veſſels

[m] Smith. [n] Gærtner.

[o] Silva and Hunter's edition. Young's annals, vol. 8.
[p] Withering.

Digitized by Google

in both are more or leſs woolly, ſo that Parkinſon's diſtinction, taken from that circumſtance, does not hold good. Ray, with his uſual caution, heſitates whether he ſhould conſider them as diſtinct ſpecies, though this is ſmaller and more humble, with ſhorter ſlenderer ſpines, of a paler green, but not leſs frequent, and flowering in autumn, when the larger ſort is for the moſt part going out of flower. He informs us alſo, that Doody had remarked this to differ from the common greater Furze, in having the branches always ſpread on the ground, the thorns ſhorter and leſs pungent, the flowers paler and not appearing before autumn. Dr. Withering diſtinguiſhes them thus; in the common one the corolla is longer than the calyx, and the thorns longer than the corolla: in the dwarf Furze the corolla is as long as the calyx, and the thorns are ſhorter than the corolla. Should theſe characters prove permanent, it will be readily allowed, he ſays, that they are diſtinct ſpecies. Dr. Stokes ſays this ſeems to be a truly diſtinct variety.

Dr. Smith ſays it is much lower than the common ſort, with decumbent branches; the ſpines horizontal or partly deflexed; the bractes very ſmall, brown, often ſcarcely apparent, preſſed cloſe to the calyx, as Mr. Stackhouſe ſuggeſted to him; calyx more ſilky and leſs tomentoſe, with the teeth very conſpicuous, deeply cut and diſtant; corolla little longer than the calyx, of a leſs flaming colour; legume rough-haired. It is found with the other chiefly on dry elevated heaths, but by no means ſo general; flowering from auguſt to october. I muſt confeſs it always appeared to me ſufficiently diſtinct from the preceding ſpecies.]

3. Stem woody and hard covered with a greeniſh bark when young, but afterwards becomes grayiſh. Branches ſlender and woody. It has not produced any flowers in the Engliſh gardens. Native of the Cape of Good Hope, where it uſually grows to the height of five or ſix feet.

PROPAGATION AND CULTURE.

1. 2. Theſe ſhrubs propagate themſelves very plentifully by ſeeds, which when ripe are caſt out of the pods to a conſiderable diſtance, and ſoon vegetate.

3. This is preſerved in the greenhouſe or dry ſtove with other hardy exotics. It is difficult to increaſe either by layers or cuttings.

DESCRIPTION

Digitized by Google

DESCRIPTIONS, &c.

1. Bark cloven, on the branches corky. Leaves rugged on both ſides, villoſe beneath along the ſmall veins. Flowers from their proper gems, cluſtered, ſcarcely peduncled, numerous, browniſh-fleſh-coloured. Capſules oblong. Timber hard tough [s]. The flowers have a violet ſmell [t].

This Elm is a very great high tree. The bark of the young trees, and the boughs of the elder trees are ſmooth and very tough, and will ſtrip or pill from the wood a great length without breaking: the bark of the body of the old tree, as the trees grow in bigneſs, tears or rents, which makes it very rough. The innermoſt wood is of a reddiſh yellow or browniſh colour and curled, and after it is dry very tough and hard to cleave. The wood next the bark or ſap is white. Before the leaves come forth, the flowers appear, about the end of march, growing on the twigs or branches, cloſely compacted or thruſt together, of a red colour: after which come flat ſeeds, more long than broad, not much unlike the garden Arach ſeed in form and bigneſs; for the moſt part falling away before or ſhortly after the leaves ſpring forth, but ſome hang on a great part of the ſummer. Leaves dark green, the middle-ſized ones two inches broad and three inches long, rough or harſh on both ſides, indented about the edges, and many times crumpled, having a nerve in the middle, and many ſmaller nerves growing from it; on one ſide always longer than on the other [u].

Native of Europe and Barbary. Linneus ſays it is ſcarcely to be found above Helſing and Finland. (64°). Evelyn informs us, that before the walks and viſtas were planted at Aranjuez, Caſal del Campo, Madrid, the Eſcurial, &c. with trees which Philip the ſecond cauſed to be brought out of England, it does not appear that there were any elms in Spain [x]. It is doubted by this learned planter and others whether the Elm be indigenous of England. Some affirm, ſays Evelyn, that it was firſt brought out of Lombardy; there are no conſiderable woods of it any where; Shropſhire and ſeveral other countries, and rarely any beyond Stamford to Durham, having any growing in many miles together [y]. Aubrey informed Mr. Ray that the Elm is not to be found to the north of Grantham or Stamford.

However this may be, we certainly poſſeſſed this tree in the Saxon times: and there can be no ſtronger proof, ſays Dr. Hunter, that the Elm is a native of England, than that there are near forty places which take their names from it, and moſt of them mentioned in Doomſday-book. Chaucer lived at Newelm in Oxfordſhire; Dryden at Nine-elms near Lambeth. There is alſo Barn-elms, &c.] Mr. Miller ſays, it is very common in the north-weſt counties of England, where it is generally believed to grow naturally in the woods.

The Elm grows to a great ſize; in little more than forty years, ſays Mr. Evelyn, it will arrive to a load of timber. He mentions many then ſtanding in Epſom pariſh, which would bear almoſt three feet ſquare for more than forty feet. An Elm planted by Henry IV. was ſtill ſtanding in the Luxembourg gardens at Paris, when the Revolution broke out; but whether it has ſurvived that event, I am unable to ſay. This great monarch's famous contemporary queen Elizabeth is ſaid to have planted an Elm with her own hand at Chelſea, where her father had a palace in which ſhe was brought up when an infant. It went always by her name, and I remember it a ſtately flouriſhing tree, except that the top was decayed. It ſtood at the upper end of Church lane, near where the turnpike now is, and was a boundary of the pariſh on the north ſide. It was felled, to the great regret of the neighbourhood, on the eleventh of november 1745, and ſold for a guinea by Sir Hans Sloane, Bart. lord of the manor. It was thirteen feet in circumference at bottom, and ſix feet ſix inches, at the height of forty-four feet: the height was one hundred and ten feet, of which fifteen feet at the top were decayed, the tree having ſuffered by the hard froſt in 1739—40.

[s] Smith. [t] Withering. [u] Goodyer in Ger. emac.
[x] Silva, b. 1. c. 4. § 7. [y] Id. ib. § 8.

In a manuſcript obligingly lent me by Craven Ord, Eſq. and probably written by Oldys, mention is made of ſeveral remarkable Elms. As of one at Charlton, in Kent, about which Horn-fair is kept, ſpreading eight yards on every ſide, the height about ten yards, but the trunk not above a foot in diameter.

One of Sir Francis Bacon's Elms in Gray's Inn walks was felled upon a ſuſpected decay in 1720 or 1726, and was above twelve feet round: it had forty-five feet of timber in it. In 1750 not above eight trees of his plantation were left. They were planted in 1600.

At Fulham are or were ſome Elms, planted in the time of king Edward VI: and one at Richmond, ſaid to be planted by a courtier of king Henry VII, whilſt that king kept his court there, and yet (in Oldys' time) in its prime.

The walk of Elms on that ſide of the Mall in St. James's Park next to the palace, are ſome of them about one hundred and ſixty years of age. One which ſtood at the upper end turning up to the Green Park, being blown down, was found to be above ſixty feet in height, and near twelve in circumference near the root. (They are now conſiderably more than two hundred years old, but very few (in 1805) are remaining, and thoſe very much decayed.)

Two Elms at St. John's College in Oxford, were ſizeable trees in the reign of queen Mary.

Stately rows of Elms at Hilhall in Eſſex, are ſaid to have been planted by Sir Thomas Smith.—So far Mr. Ord's manuſcript.

Mr. Boutcher informs us that he ſold a line of Engliſh Elms, above ſixty in number, at a guinea a tree, at twenty-four year's growth: they were about eighteen inches in diameter, a foot above ground, and forty feet high.

Mr. Coxe, in his account of Monmouthſhire, mentions an ancient Elm at Raglan Caſtle, which is twenty-eight feet five inches in circumference near the root.

Mr. Marſhall ſays, the largeſt Elms he has ſeen of the fine-leaved ſort, as he calls it, grow in the Vale of Gloceſter; and that there are ſeveral in the pariſh of Church-down, which girt, at five feet high, from ten to twelve feet. But the fineſt Elm in the vale ſtands in the road between Cheltenham and Tewkeſbury, within a few hundred yards of the Boddington Oak. It is known by the name of Piffe's Elm; and the toll-gate is called Piffe's Elm pike. The ſmalleſt girt of this tree, which falls about five feet high, was in 1783 exactly ſixteen feet. At ten feet high it throws out large arms, which have formerly been lopped, but are now furniſhed with tree-like ſhoots, riſing ſeventy or eighty feet high, with an extent proportionable. There is an Elm of the ſmall-leaved ſort in Hyde Park, the ſtem of which is larger than this; but it is hollow, its head much impaired, and is a mere dotard compared with Piffe's Elm [z].

Elm timber, ſays Mr. Evelyn, is of ſingular uſe; eſpecially where it may lie continually dry, or wet, in extreams; therefore proper for water-works, mills, the ladles and ſoles of the wheel, pipes, pumps, aquæducts, pales, ſhip planks beneath the water-line: alſo for wheelrights, handles for the ſingle hand-ſaw. Rails and gates of Elm, thin-ſawed, are not ſo apt to rive as Oak. The knotty for naves and hubs; the ſtraight and ſmooth for axle-trees; and the very roots for curiouſly dappled works. It has ſcarce any ſuperior for kerbs of coppers, feather edge, and weather-boards; but it does not without difficulty admit the nail, without boreing. Chopping-blocks, blocks for the hat-maker, trunks and boxes to be covered with leather; coffins; dreſſers and ſhovel-board tables of great length, of a luſtrous colour, if rightly ſeaſoned. Alſo and for the carver by reaſon of the tenor of the grain, and toughneſs which fits it for all thoſe curious works of frutages, foliage, ſhields, ſtatues, and moſt of the ornaments appertaining to the orders of architecture, and for not being much ſubject to warping. Vitruvius commends it both for tenons and mortaiſes. It makes alſo the ſecond ſort of charcoal [a].

Mr. Marſhall adds, that in places where bricks are rendered dear, by the want of a proper ſupply of fuel,

[z] Planting, 2. 429. [a] Silva, b. 1. c. 4.

Digitized by Google

as in Surry and Kent, great quantities of this tree are cut up for ſtuds and weather-boarding for the ſides of barns, ſtables, and even dwelling-houſes: and in the ſouthern counties in general it is much uſed in carpenter's work of all kinds as a ſubſtitute for oak [z].

The bark dried and ground to powder has been mixed with meal in Norway to make bread, in times of ſcarcity.—The leaves ſuffered to dry upon the branches, and laid up in a dry barn prove a great relief to cattle in winter, where fodder is ſcarce: they are acceptable to horſes, kine, ſheep, goats, and ſwine. In ſome parts of Herefordſhire they gather them in ſacks for this purpoſe. It is ſaid that ſilk-worms will devour the leaves when tender with great avidity [a].

The inner tough bark has no remarkable ſmell, but a bitteriſh taſte, and abounds with a ſlimy juice, which has been recommended in nephritic caſes, and externally as a uſeful application to burns; the bark of the branches is more bitter than that of the trunk, and therefore probably more efficacious.

The complaints for which it is chiefly recommended are of the cutaneous kind allied to herpes and lepra. A decoction drank freely has been known to carry off the water in dropſies. Dr. Lettſom found it moſt effectual in what he ſuppoſes to be the lepra ichthyoſis of Sauvages, in which it ſucceeded after all the medicines uſually employed in ſuch caſes had failed. A remarkable inſtance of its efficacy alſo in lepra vulgaris, affecting the whole body, is related by Banau; who propoſes its uſe in various other diſeaſes, as fluor albus, rheumatiſm, old ulcers, cancerous and ſcrophulous affections, tinea capitis, ſcurvy, &c. In very obſtinate caſes it is neceſſary to perſevere in the uſe of the decoction for ſome months [b].

Elm twigs were anciently uſed as inſtruments of caſtigation. For Plautus ſpeaks of a rogue who had been chaſtiſed ſo often, that he had waſted all the Elms in the country in rods and cudgels.

The Elm, ſays Mr. Gilpin, naturally grows upright; and when it meets with a ſoil it loves, riſes higher than the generality of trees; and after it has aſſumed the dignity and hoary roughneſs of age, few of its foreſt brethren, though properly ſpeaking it is not a foreſter, excel it in grandeur and beauty. The character of the Elm, in its ſkeleton partakes much of the Oak; ſo much, that when it is rough and old, it may eaſily, at a little diſtance, be miſtaken for an Oak. In full foliage its character is better marked; and no tree is better adapted to receive grand maſſes of light; nor is its foliage, ſhadowing as it is, of the heavy kind. Its leaves are ſmall, and this gives it a natural lightneſs; it commonly hangs looſely, and is in general very pictureſque [c].

β. The narrow-leaved Elm is like the other, but much leſſer and lower; the leaves are uſually about two inches and a half long, and an inch or an inch and quarter broad; indented about the edges, and having one ſide longer than the other, and being harſh on both ſides like the other. Mr. Goodyer ſays he ſaw it growing but once, and that in the hedges by the high road between Chriſtchurch and Limmington in the new foreſt in Hampſhire, about the middle of ſeptember 1624; and that he brought ſome ſmall plants of it, not a foot in length, which when he was giving this account in 1633, were riſing up ten or twelve feet high, and growing with him by the other, were eaſily to be diſcerned apart [d].]

This is called in the nurſeries the Engliſh Elm; Mr. Miller ſays improperly, for it is not a native of England, and is only found near London, or in plantations where the trees were procured from that neighbourhood. Some perſons, he ſays, have ſuppoſed that it was brought from Germany. [Dr. Smith ſtates it to be the opinion of Mr. Crowe, that this is the origin of all the cultivated varieties.

Mr. Miller ſays, that there are ſeveral other varieties, but not worth noticing; among theſe is that with variegated or blotched leaves. Mr. Gilpin mentions the

[z] Planting, 2. 430. [a] Evelyn, b. 1. c. 5. and Withering, 278. note. Tranſ. Arts, 2. 157. [b] Woodville, 541. Withering. Med. tranſ. 2. 203. Med. mem. 152. [c] Foreſt ſcenery, 1. 39, 40. [d] Goodyer in Ger. emac. 1480.

Weeping Elm, of which the fineſt ſpecimens are in St. John's Walks at Cambridge.

2. The cork-barked, or as we commonly call it, the Dutch Elm, becauſe it was introduced from Holland at the beginning of king William's reign, is chiefly remarkable for its quick growth, and fungous rough bark. The leaves are very large and harſh on both ſides, not ſo unequal at the baſe as the others. The flowers according to Schkuhr and Willdenow, have only four ſtamens. Native of Europe. The wood is of very inferior quality.

3. The broad-leaved Elm, called alſo the Wych Haſel, has the bark of the branchlets ſmooth and even. The leaves are wider than in the preceding, leſs harſh, and acuminate. The flowers are on longer peduncles, and ſpread out looſely. The fruit is roundiſh. The wood is leſs ſolid [e].

The trunk ſoon divides into long wide-ſpreading winged branches; and when at its full growth ſeldom riſes to above one-third of the height of the campeſtris. It flowers when even under thirty feet high, whilſt that ſeldom flowers till it has gained a much greater age and height. The branches are very brittle. Leaf-buds and flower-buds diſtant. Flowers ſcentleſs, from ſix to fifteen in a corymb, on long pedicels: clefts of the calyx five, ſix, and in one inſtance four and nine. Stamens five and ſix (according to Schkuhr eight.) Stigmas three [f]. This groweth, ſays Goodyer, to be a very great tree, and alſo very high, eſpecially in woods among other trees. The bark on the outſide is blacker than that of the firſt, and is alſo very tough, ſo that when there is plenty of ſap, it will ſtrip or peel from the wood of the boughs from the one end to the other, a dozen feet in length or more without breaking; whereof ropes are often made. The timber hereof is in colour near like the firſt: it is not ſo firm or ſtrong for naves, but will more eaſily cleave. The branches or young boughs are groſſer and bigger, and do ſpread themſelves broader, and hang more downwards. The ſeed is ſomewhat bigger. The leaves are much broader and longer than any of the kinds of Elm, uſually three or four inches broad, and five or ſix inches long, alſo harſh on both ſides, indented about the edges, near reſembling the leaves of the Haſel; the one ſide of them is moſt commonly longer than the other. This proſpereth and groweth naturally in any ſoil moiſt or dry, on high hills and in low vallies in good plenty in moſt places in Hampſhire, where it is commonly called Witch Haſell. Old men affirm, that when long bows were in uſe, there were very many made of the wood of this tree, for which purpoſe it is mentioned in the Engliſh Statutes by this name of Witch Haſell. It hath little affinity with Carpinus, which in Eſſex is called Witch Haſell [g].

It is found in ſhady lanes and the outſkirts of woods in moſt parts of England, and ſeems clearly to be indigenous. In Scotland and the north of England, it appears to prevail more peculiarly, from the ſcarcity of the campeſtris, which is found only near villages; whereas this is found in woods and brakes, as well as hedgerows [h].

Mr. Cook mentions a Witch Elm felled in Sir Walter Bagot's park in Staffordſhire, which lay forty yards in length; was at the ſtool ſeventeen feet diameter; broke in the fall fourteen load of wood, forty-eight load in the top; yielded eight pair of naves, eight thouſand ſix hundred and ſixty feet of boards and planks: the whole was eſteemed ninety-ſeven tuns [i].

A Wych Hazel, though it had loſt a conſiderable leading branch in the great ſtorm of 1703, yet when felled contained eight loads of timber, and being ſawn off at ſeven feet above the but, meaſured near eight feet in diameter. It was a planted tree [k].

The Wich Elm, ſays Mr. Gilpin, is perhaps generally more pictureſque than the common ſort, as it hangs more negligently; though at the ſame time with this negligence, it loſes, in a good degree, that happy ſurface for catching maſſes of light, which we admire in the common Elm. We obſerve alſo, when we ſee

[e] Smith. [f] Stokes and Gough in Withering. [g] Ger. emac. 1481. [h] Stokes in Withering. [i] Evelyn, b. 3. c. 3. [k] White's Selburne.

this

this tree in company with that, its barkis ſomewhat of a lighter hue. The Wich Elm is found in Scotland, not only in the plains and vallies of the Lowlands; but is hardy enough to climb the ſteeps and flouriſh in the remoteſt Highlands, though it does not attain, in thoſe climates, the ſize to which it grows in England[l].

I have preſerved the various orthography of different authors, not knowing which is right. Old writers always ſpell it *Witch*, as Goodyer, Ray, Evelyn, &c. and it is ſo pronounced in ſome parts; but the prevailing mode of pronunciation and ſpelling ſeems now to be *Wych*, and this tree is commonly called by that name, without the adjunct of Elm or Haſel. Mr. Gilpin is ſingular in his mode of orthography.

This ſpecies being undoubtedly indigenous, and formerly much uſed for bows, if it could be proved that it was anciently known by the name of Elm, probably was the occaſion of Elm forming part of the appellation of ſo many villages, and not the campeſtris. It is certain however that in the Statutes it is called Witch Haſell.

The timber of this tree may be applied to the ſame uſes with the other, but it is inferior in toughneſs and ſtrength.

β. The ſmooth-leaved Elm is in bigneſs and height like the firſt, but the boughs grow as thoſe of the Witch Haſell do, hanging more downwards than thoſe of the common Elm. The bark is blacker than that of the firſt kind, but will alſo peel from the boughs. The flowers and ſeeds are like thoſe of the firſt. The leaves alſo, in form, are like that, but ſmooth in handling on both ſides. My worthy friend and excellent Herbariſt of happy memory, Mr. William Coys of Stubbers in the pariſh of Northokington in Eſſex, told me, that the wood of this kind was more deſired for naves of carts than that of the firſt. I obſerved it growing very plentifully as I rode between Rumford and the ſaid Stubbers, in the year 1620, intermixed with the firſt kind, but eaſily to be diſcerned apart. It is in thoſe parts uſually called Witch Elm[m]. Mr. James Sherard obſerved it in the road beyond Dartford in Kent. Ray remarks that it is very frequent in Cambridgeſhire. It is ſo ſtill, and I have ſometimes thought that it bids at leaſt as fair as the Dutch Elm to be taken for a diſtinct ſpecies. Dr. Plot ſpeaks of a variety of this with narrower and more acuminate leaves. *Miller, n.* 6.

Linneus conſidered all the European Elms as making only one ſpecies; Goodyer, as we have ſeen, deſcribed four. Ray followed him. Our modern Botaniſts diſtinguiſh two ſpecies, and conſider each of the two others as forming a variety of theſe. The German botaniſts make the Dutch Elm a third ſpecies, not merely from the cork-like appearance of the bark on the twigs, but alſo becauſe the flowers have only four ſtamens; whereas the campeſtris has five, and the montana eight. But the number of ſtamens is too uncertain to form ſpecific characters upon them only.]

Mr. Miller has ſix ſpecies. 1. Ulmus campeſtris. The common rough, or broad-leaved Witch Elm. The Mountain Elm of Evelyn. The branches ſpread, and do not grow ſo erect as thoſe of the third ſort. The leaves about three inches long and two broad, on ſhort foot-ſtalks. The flowers come out in march upon the ſlender twigs, in cluſters; they are of a deep red colour, and are ſucceeded by oval bordered capſules, containing one roundiſh compreſſed ſeed, which ripens in may. The leaves not coming out till late in the ſpring, few perſons plant this tree near their habitations.

2. Ulmus ſcabra. The Witch Hazel, or rough and very broad-leaved Elm; by ſome unſkilful perſons called the Britiſh Elm. (Ulmus montana, n. 3.) This grows naturally in the north of England where it is frequently called Witch Hazel, from the reſemblance of the young ſhoots and leaves to thoſe of Hazel. They are ſix inches long, and almoſt four broad. It grows to a great ſize: the bark of the young ſhoots is very ſmooth and tough, of a yellowiſh brown colour with ſpots of white. The flowers grow in cluſters towards the end of the twigs; they have long leafy calyxes of a green colour, and appear in the ſpring before the leaves: the ſeeds ripen at the end of may. The wood is inferior to that of the firſt ſort.

[This, ſays Mr. Evelyn, (ſilva, b. 1. c. 4. §. 5.) has a more ſcabrous harſh leaf, but very large, it becomes an hugh tree, and is diſtinguiſhed by the name of Witch Hazel in our Statute Books, as ſerving formerly to make long Bowes of. The timber is not ſo good as the firſt more vulgar; but the bark at time of year, will ſerve to make a coarſe baſt-rope with.

This ſort is not proper for hedge-rows, but for woods. There, being planted near each other, inſtead of throwing out their monſtrous arms, they will aſpire, and carry up a noble trunk to a vaſt height[n].]

3. Ulmus ſativa. Small-leaved or Engliſh Elm; (by ſome called Corniſh Elm.) The flowers are of a purpliſh red colour, and generally appear the beginning of march; but Mr. Miller ſays that he could never obſerve any ſeeds upon this ſort. It is a variety of the firſt.

4. Ulmus glabra. Smooth-leaved Witch Elm. (called by Evelyn the French Elm. U. montana β. n. 3.) It is very common in ſeveral parts of Hertfordſhire, Eſſex and other north-eaſt counties: grows to a large tree and is much eſteemed. The branches ſpread out like thoſe of the firſt ſort. The leaves are ovate, ſharply ſerrate, ſmoother than the other ſorts, and do not appear till the middle or end of may; for which reaſon it is ſeldom planted near habitations.

[Mr. Evelyn ſays, the leaves are thicker and more florid, glabrous and ſmooth, delighting in lower and moiſter grounds, where it will ſometimes riſe to above an hundred feet in height, and a prodigious growth, in leſs than an age; myſelf having ſeen one planted by the hand of a counteſs living not long ſince, which was near twelve feet in compaſs, and of an height proportionable[o].]

5. Ulmus hollandica. The Dutch Elm. (U. ſuberoſa, n. 2.) It was brought from Holland in the beginning of king William's reign; was for ſome time a faſhionable tree, and was recommended for its quick growth. It was in great requeſt for forming hedges in gardens, for which purpoſe it was one of the moſt improper trees that could be choſen, on account of its very ſtrong irregular ſhoots, which are diſtant from each other. The leaves are very large and rough, and the branches being covered with a fungous bark, when the hedges were ſheared, they appeared naked the whole ſummer after. The wood of this tree being good for nothing, it is almoſt baniſhed this country.

6. Ulmus minor. The ſmooth narrow-leaved Elm; by ſome called the Upright Elm; by others the Iriſh Elm. The branches have a ſmooth grayiſh bark, and grow erect. The leaves are narrower and more pointed than thoſe of the Engliſh Elm, and are ſmoother: they are later in coming out in the ſpring, but continue longer in autumn. It is found in hedgerows in ſeveral parts of England: [and ſeems to be a variety of the ſmooth-leaved Elm, n. 3. β.

Mr. Hanbury enumerates ſeven ſorts of the European Elm. 1. The true Engliſh Elm. 2. The narrow-leaved Corniſh Elm. 3. The Dutch Elm. 4. The black Worceſterſhire Elm. 5. The narrow-leaved Wych Elm. 6. The Broad-leaved Wych Elm. 7. The upright Wych Elm.

He obſerves however that it would be endleſs to enumerate all the ſorts, (or rather varieties), having counted more than twenty in woods and hedges.

Upon which Mr. Marſhall juſtly remarks, that although we ſee, among cultivated Elms, individuals widely different from each other, yet every man who has attended cloſely to theſe trees as they grow in different ſoils and ſituations, muſt have obſerved ſuch a chain of intermediate varieties, as renders it very difficult to diſtinguiſh them ſpecifically; and muſt frequently have met with an individual, which he was puzzled to find a name for. He allows however that we cannot deſcribe more than two obviouſly diſtant varieties, (or ſpecies as our modern Engliſh botaniſts think them to be.) Theſe he calls 1. The Coarſe-

[l] Foreſt ſcenery, 1. 41. [m] Goodyer in Ger. emac. 1482. [n] Hunter on Evel. ſilva. [o] Silva, b. 1. c. 4.

Digitized by Google

leaved Elm; the Cheſnut-leaved, the broad-leaved, the Wych Elm, or the North-country Elm. (Our Ulmus montana.)

2. The Fine-leaved Elm; the Hazel-leaved, Narrow-leaved, or South-country Elm, (Our Ulmus campeſtris.)

If we examine, he ſays, the extremes of the chain of varieties, we ſhall find two very different in their general appearance, and ſufficiently diſtinct to be conſidered as diſtinct ſpecies. The leaf of the one is nearly oval, with an obtuſe lance-like point; that of the other is nearly circular, ſaving a narrow ſlender point, growing as it were out of the periphery of the circle. The membrane of the one is groſs and rigid, of the other comparatively thin, delicate and ſupple: when held againſt a ſtrong light, the former appears opake; the latter comparatively tranſparent. The nerves of that are ſtronger, ſet cloſer, and run more parallel: of this more ſlender, fewer in number, and dividing more into branches. That, in its general appearance, bears ſome reſemblance to the leaf of the Cheſnut; this, a very ſtrong one to that of the Hazell. The branches of the Coarſe-leaved ſort are clear, ſtraight and ſlender, with a ſilvery bark: thoſe of the fine-leaved are more divided, run ſhorter lengths, and are covered with a leſs delicate bark. The general tendency of the latter is more upright, being eaſily trained to a greater length of ſtem: that of the former is to divide into ſpreading arms, and when attempted to be trained up with a tall ſtraight ſtem, generally grows ſtooping with a nodding head like the panicle of an oat. The Coarſe-leaved Elm matures its ſeed in this iſland, and is probably a native: the Fine-leaved ſeldom if ever perfects its ſeed with us, and is probably an exotic.

The Coarſe-leaved Elm will grow to a very great ſize. Mr. Marſham mentions a Wych Elm by Bradley Church in Suffolk, which in 1754, at five feet high, meaſured twenty-five feet five inches and a half round, and in 1767, twenty-ſix feet three inches.

The general appearance of this tree ſometimes comes near to that of the Oak: but in general it is liable to be ragged, rather than irregular, and in point of ornament is frequently exceeded by the Lime, the Beech and the Fine-leaved Elm.

The whole tribe of Elms have a peculiar excellency by which they ſtand alone, and are rendered in a great meaſure independent of other woods; namely, their tenacity or adheſive quality, being leſs liable to be ſplit than other woods: this renders them ſingularly uſeful for many important purpoſes. The keels of ſhips are now almoſt univerſally laid with Elm; and ſometimes the gunwales, eſpecially of ſhips of war, are made of this wood; it being leſs liable to ſplinter off in action even than Engliſh Oak; as keels made of this wood are leſs apt to ſplit in taking the ground. Another very important uſe of Elm is for naves of carriage wheels, both of uſe and pleaſure. There is a ſort in Yorkſhire peculiarly adapted to this purpoſe, which goes by the name of the Nave Elm. It is of the coarſe-leaved kind.

The Fine-leaved Elm will alſo grow to a great height and conſiderable bulk. Notwithſtanding we are accuſtomed to ſee the hedge-row Elms trimmed up to mere may-poles, or at beſt with cloſe aſpiring heads; yet, if planted ſingly, and ſuffered to form their own heads, they will take an outline equal to that of the Beech or Lime: and where an immediate object or ſkreen is wanted the Elm has two advantages; it may be removed when of a great ſize, and its growth is quicker than that of any other tree which is equally ornamental. The uſes of it are ſimilar to thoſe of the Coarſe-leaved kind [p].

We now turn to the American Elms, which are not noticed by Mr. Miller, though they were cultivated by Mr. James Gordon in 1752; that is ſixteen years before the laſt folio edition of the Dictionary was publiſhed.

4. Three varieties of the American Elm are mentioned in the catalogue of the Royal Botanic Garden at Kew.

1. The Red or Canada Elm, which grows in its native country to a vaſt ſize. The leaves are ovate, wrinkled and ſcabrous, broader than thoſe of our Dutch or Wych Elms, ſmoother and of a much more lively green. The branches are red, whence it has the name of Red Elm. It grows very faſt here [q]. Gronovius diſtinguiſhes it from the White, not only by the leaves, but by its not attaining ſo great a height or thickneſs.

2. The White Elm is ſo named from the whiteneſs of the branches. The leaves are ſcabrous, but oblong. Gronovius deſcribes it as having narrower leaves than the red, and the trunk beſet at intervals with twigs cloſely cluſtered together below the boughs. Boats are made from the bark of it. Kalm deſcribes the method of making them very particularly. He ſays that the White and Red Elm are ſo called from the colour of the wood [r].

3. The Drooping or Weeping Elm; diſtinguiſhed by its oblong ſmoothiſh leaves, and its pendent branches.

The American differs from the European Elm in having the leaves equally, or as Gronovius expreſſes it quite ſimply or ſingly ſerrate.

Gærtner deſcribes the fruit as a ſuperior, leafy-compreſſed, obovate capſule, attenuated into the peduncle which is guarded by the permanent calyx, one-celled, valveleſs: cell in the centre of the capſule, ſpongy on the outſide, very ſmooth within, compreſſed like a lens. Seed ovate, pointed at the end, compreſſed like a lens, of a greeniſh bay colour; faſtened by a thread which ſprings from the top of the cell, and adheres to one margin of the ſeed to the very baſe.

Native of the foreſts of Virginia and other parts of North America.

5. The Hornbeam-leaved Elm is alſo a native of North America; and was cultivated by Mr. James Gordon in 1760.

6. In ſouthern Ruſſia, the Ulmus pumila often contends with the Oak in ſtature. The branches are more ſlender than in the other ſpecies, divaricating, and of a grayiſh aſh-colour. Leaves alternate, ſome ſimply, others unequally, others again doubly ſerrate, ſmoother than in U. lævis, (our campeſtris β); equal or unequal at the baſe, leſs ſo however than in the others, and the petioles a little longer: both petioles and twigs are ſmooth. Stipules ruſt-coloured, membranaceous-briſtle-ſhaped. Seeds on ſhort peduncles, collected into ſeſſile globular umbels; the ſurrounding membrane is almoſt orbicular, cut but not acuminate, with the teeth of the cut very ſhortly curved in; it is ſmooth, very tender, and finely veined, pale gray: the ſeed itſelf is alſo gray; and ripens in may, if not ſooner.

Wood very hard, and tough, gray, remarkably waved with tranſverſe lines of a deeper colour, larger fibred, and when expoſed to the air becomes yellower than Oak, and is preferable to it. The aſhes exported from Riga under the name of *Waidaſche* are made entirely from the wood of this and other Elms, burnt in brick furnaces. The root is beautifully variegated and fit for the uſe of the turner, &c. The bark does not readily peel off, and therefore is not uſed for making ropes.

A variety of this is common, with both young and old branches winged and rendered irregular with compreſſed fungous excreſcences of the bark variouſly interrupted.

Beyond the lake Baikal, on the banks of the lake it differs leſs, but in the mountains very much, from the Ruſſian. The branches are ſlender, wand-like, whitiſh-gray, divaricating. Leaves frequent, ſmall, lanceolate, equal at the baſe, uniformly ſerrate, the ſerratures very ſeldom cut. Petioles longiſh, ſcarcely pubeſcent. Stipules membranaceous-ſetaceous. Seeds ſmaller and whiter, on very ſhort peduncles, almoſt orbicular, except the notch, and the linear proceſs by which they are inſerted into the calyx. They ripen in june.

In mountain rocks there is a variety with ſhorter, thicker branches, winged with fungous excreſcences of the bark. When Pallas obſerved it in the middle of may, it was in flower without leaves: the flowers duſky purple.

[p] Planting, vol. 2. p. 424. ed. 2.

[q] Hunter on Evelyn and Ait. kew. [r] Travels, vol. 2. p. 298. Engl. edit.

Digitized by Google

purple, pubeſcent, ſeſſile, in ſubſeſſile little balls; with large, twin, pale anthers, edged with red.

In ſandy lands on the contrary the trees are ſmall, very finely branched, with ſmall leaves, full of bladders formed by the Chermes.

The leaves, in this part of Ruſſia, are ſometimes uſed as a ſuccedaneum for Tea.

Beſides this, Pallas has our ſmall-leaved Elm, (U. campeſtris β), which he names Ulmus lævis.—Ulmus campeſtris, our common Elm, n. 1.—And U. hollandica; which he thinks may be a degenerate variety of the campeſtris *; and in that I cannot but agree with him.

7. Trunk ſtraight and high. Bark a little ſcabrous, of a dirty-gray colour. Branches numerous, ſpreading ſo as to form a large ſhady head. Leaves alternate, two-faced, ſhort-petioled, ovate (ſometimes cordate); entire, ſmooth, ſhining; from three to five inches long, and about two broad. Stipules lanceolate, falling. Flowers hermaphrodite and male mixed, from little gems over the naked branchlets. Calyx four, five or ſix-leaved: leaflets ſpreading, ſmall, oval, falling. Filaments ſeven, eight, or nine, exceedingly ſhort. Anthers linear, erect, two-lobed. Germ ſuperior, obovate, emarginate, compreſſed. Styles two, ſhort, incurved, permanent. Stigmas acute, woolly. Capſule pedicelled, orbicular, leafy, compreſſed, emarginate, one-celled, one-valved, not opening. Seed one. The male flowers are the ſame, except that there is no rudiment of a piſtil.

The firſt parts of the flower that appear, are the anthers, which are then reddiſh; next the calyx increaſes, and becomes viſible to the naked eye, but is at all times ſmall, and if not looked for, may paſs unperceived.

This whole leaved Elm is a very large timber tree, a native of the Circar mountains; called by the Telingas *Naulie*. It flowers during the cold ſeaſon, and caſts its leaves about the cloſe of the wet ſeaſon; but theſe come out again in march. The wood is by the natives reckoned of a good quality, and employed for a variety of uſes †.]

PROPAGATION AND CULTURE.

All the ſorts of Elm may be either propagated by layers or ſuckers taken from the roots of the old trees, the latter of which is generally practiſed by the nurſery gardeners; but as theſe are often cut up with indifferent roots, they often miſcarry, and render the ſucceſs doubtful; whereas thoſe which are propagated by layers are in no hazard, and always make better roots, and come on faſter than the other, and do not ſend out ſuckers from their roots in ſuch plenty, for which reaſon this method ſhould be more univerſally practiſed. And ſince a ſmall compaſs of ground filled with ſtools of theſe plants will be ſufficient to furniſh a nurſery of a conſiderable extent, annually, with layers to be tranſplanted, it is richly worth every perſon's while, who would cultivate theſe trees, to allot a ſpot of ground for this purpoſe.

The beſt ſoil for ſuch a nurſery is a freſh Hazel loam, neither too light and dry, nor over moiſt and heavy; this ground ſhould be well trenched, and if a little rotten dung is buried therein, it will be of ſervice; in doing of this great care ſhould be taken to pick out all the roots of pernicious weeds, which, if left in the ground, would be very injurious to the layers, and cannot afterwards be ſo eaſily rooted out; then having laid the ground level, the plants muſt be planted at about eight feet aſunder each way. The beſt ſeaſon for this work is in autumn, as ſoon as the leaves begin to decay, that they may take root before the dry weather in the ſpring comes on, whereby a great expence of watering them will be ſaved; for if they are well ſettled in the ground before the dry weather, they will require little more than to mulch their roots to keep the earth from drying.

Theſe plants ſhould be permitted to grow rude two years, during which time the ground between ſhould be carefully cleaned and dug every ſpring, by which time they will be well rooted and have made pretty ſtrong ſhoots, ſo that they may be laid in the ground. The manner of performing this being already described in the article LAYING, I ſhall forbear repeating it in this place.

When theſe layers are well rooted, which will be in one year, they ſhould be taken off, and tranſplanted out into a nurſery, which ſhould be upon a good ſoil, and well prepared, (as before for the ſtools.) The plants ſhould be planted in rows about four feet aſunder, and two feet diſtance plant from plant in the rows. This ſhould be done in autumn as ſoon as the leaves begin to decay, and if there is ſome mulch laid upon the ſurface of the ground about their roots, it will preſerve them from being hurt by froſt in winter, and from drying winds in ſpring, and thereby ſecure them from all hazard.

The following ſummer the ground between them ſhould be conſtantly kept clean from weeds, and in autumn they ſhould be pruned up, cutting off all ſtrong lateral branches, which, if left on, would impede their upright growth; but there muſt be ſome of the ſmaller ſhoots left on to detain the ſap, in order to augment the ſtems of the trees; for where they are pruned up too naked, they are apt to grow up too ſlender to ſupport themſelves, ſo that their heads will recline to the ground, and cauſe their ſtems to grow crooked.

In this nurſery they may remain four or five years, obſerving conſtantly to dig the ground between them every ſpring, and to trim them as before directed, which will promote their growth, and render them ſtrong enough to tranſplant out where they are to remain, in the time before mentioned.

All ſorts of Elms, the Wych excepted, on account of the large arms which it throws out, are very proper to plant in hedge-rows, upon the borders of fields, where they will thrive much better than when planted in a wood, or cloſe plantation, and their ſhade will not be very injurious to whatever grows under them; but when theſe trees are tranſplanted out upon banks after this manner, the banks ſhould be well wrought, and cleared from all other roots, otherwiſe the plants, being taken from a better ſoil, will not make much progreſs in theſe places. About michaelmas will be a good time for this work, for the reaſons before aſſigned; but when they are planted, there ſhould be ſome ſtakes fixed in by them, to which they ſhould be faſtened to prevent their being diſplaced by the winds, and part of their heads ſhould be taken off before they are planted, which will alſo be of uſe in preventing their being eaſily overturned by winds; but by no means ſhould their leading ſhoot be ſtopped, nor the branches too cloſely cut off; for if there are not ſome ſhoots left on to draw and attract the ſap, they will be in danger of miſcarrying.

Theſe trees are alſo proper to plant at a diſtance from a garden or building to break the violence of winds, for which purpoſe there is not any tree more uſeful, for they may be trained up in form of a hedge, keeping them cut every year, which will cauſe them to grow very cloſe and handſome to the height of forty or fifty feet, and be a great protection againſt the fury of winds; but they ſhould not be planted too near a garden, where fruit trees or other plants are placed, becauſe the roots of the Elms run ſuperficially near the top of the ground to a great diſtance, and will intermix with the roots of the other trees, and deprive them of nouriſhment; nor ſhould they be planted near gravel or graſs walks, which are deſigned to be well kept, becauſe the roots will run into them, and ſend forth ſuckers in great plenty, which will deface the walks, and render them unſightly.

But for large gardens, where ſhade is required, there is ſcarcely any tree ſo proper for that purpoſe, being eaſy to remove when grown to a conſiderable ſize, ſo that a perſon who is willing to have his plantations for ſhade in a ſhort time, may procure trees of near one foot circumference in their trunk, which will be in little danger of ſucceeding, provided they are removed with care. And theſe will take root, and grow very well, though not ſo well as young plants, which is what few other ſorts of trees will do; but then they ſhould be ſuch trees as have been thus regularly trained up in a nurſery, and have good roots, and not ſuch

* Flora Roſſica. † Roxburgh.

Digitized by Google

as are taken out of hedge-rows (as is by ſome practiſed,) which ſeldom riſe with any tolerable roots and conſequently often miſcarry; and this has been the occaſion of ſo many plantations of theſe trees failing, for although ſome of them may live a few years, yet few of them are of long duration, and they rarely increaſe much in their ſtems, but frequently grow hollow, their heart decaying firſt, ſo that they are ſupported only by their bark or ſhell, for a few years, and the firſt ſevere winter, or very dry ſummer, they are generally deſtroyed.

But although I have ſaid, that Elms which are trained up in a nurſery may be removed with ſafety, at a larger ſize than moſt other trees, yet I would not have it underſtood that by this I would recommend the planting of them when large, for if people would have a little patience when they plant, and never plant any of theſe trees which are more than four or five inches in the girt of their ſtems, they will in a few years become better trees than any of thoſe which are tranſplanted of a much larger growth, and they will always grow to a much larger ſize; beſides, they are much more eaſily removed, and do not require to be ſo ſtrongly ſupported, nor is there much danger of the young trees miſcarrying; therefore it is much more eligible to make choice of young thriving trees (but not out of a better ſoil than that where they are to be planted,) and never to plant any large trees, unleſs where a ſmall number may be wanted for an immediate ſhade, and in ſuch caſes it is always proper to plant ſome young trees amongſt the large ones, to ſucceed them when they fail.

In planting of theſe trees great care muſt be taken not to bury their roots too deep, which is very injurious to them, eſpecially if they are planted on a moiſt loam or clay; in which caſe, if the clay is near the ſurface, it will be the beſt way to raiſe the ground, in a hill, where each tree is to be planted, which will advance their roots above the ſurface of the ground, ſo that they will not be in danger of rotting in winter with moiſture.

When theſe trees are propagated by ſuckers taken from the foot of old trees, they are commonly laid into the ground in rows pretty cloſe together in beds, where in dry weather, they may be frequently watered to encourage their putting out roots. In theſe beds they are left commonly two years, by which time thoſe that live will be rooted (though a great many of them generally die;) they then are tranſplanted into the nurſery, and managed as has been directed for the layers.

There are ſome who raiſe the Witch Elm from ſeeds which it generally produces in great plenty, and they are ripe in may; theſe ſhould be ſown upon a bed of freſh loamy earth, and gently covered. In dry weather they ſhould be watered, and if the bed is ſhaded from the violent heat of the ſun, it will be of great ſervice to the ſeeds (for I always obſerve the plants to come up better in the ſhade, than when expoſed to the ſun.) When the plants come up, they ſhould be carefully cleared from weeds, and after they have ſtood two years in the ſeed-bed, they will be fit to plant out into the nurſery, where they muſt be managed as the former.

When we view many of the late plantations which have been made in parks and gardens within forty years paſt, at a very great expence, and obſerve the little progreſs they have made, it is enough to deter others from attempting to make plantations of this tree; for, as great part of the trees have been taken out of hedge-rows and from places where they have ſprung up from the roots of old trees, they had but few roots, and thoſe not furniſhed with fibres, ſo ſuch of the trees as ſurvived their removal have made ſcarce any progreſs; and I have ſeen many plantations which had been growing ten, twelve, or more years, almoſt totally deſtroyed in a ſevere winter, and ſometimes by a very dry ſummer; for, as their roots had not extended far in the ground, the trees were weak, and though they kept alive, yet were not able to reſiſt a ſevere froſt, or a great drought; but the planters were in a hurry, and wanted immediate ſhade and proſpect, ſo in order to obtain theſe, purſued a method

in which they could never hope to have either, in any degree of perfection; whereas if they had planted trees no bigger in their ſtems than a man's thumb, in ten or twelve years time they would have had both, with the pleaſure of ſeeing an annual progreſs of their trees, at a time when their large-planted trees are decaying.

I have ſeen ſome expenſive plantations of this kind, which have ſeemed to ſucceed for two or three years, by making ſtrong ſhoots moſt part of the length of their ſtems, which has greatly deceived their planters, who did not doubt but their trees were out of danger, but in a few years after, they found moſt of their tops decay, and their hearts were rotting apace, ſo became hollow; and although they continued to put out lateral ſhoots, yet their ſtems never increaſed in ſize.

In ſome plantations made in the ſame place a few years after, with trees not a tenth part ſo large as the former, they are now more than double the ſize of the large ones, and in a moſt thriving ſtate, whereas the others do little more than juſt keep alive; therefore I adviſe every perſon, who wiſhes to have his trees thrive and become large, to plant them young, which may be performed for a very ſmall ſum, when compared with that of the other.

Another piece of advice may be alſo neceſſary here, which is not to top or cut the trees, as is too much practiſed near London, which not only impedes their growth, but occaſions their decaying ſoon.

[In order to raiſe the Elm from ſeed, gather the ſeeds at the beginning of june; ſpread them in a dry place for a few days. Mark out beds four feet wide, with alleys between them a foot and half or two feet broad. Sow the ſeeds thinly over the beds, and cover them with thin mould near half an inch thick. Hoop the beds in order to cover them with mats occaſionally in hot weather; when they muſt alſo be ſometimes refreſhed with water. In about a month many of the young plants will appear, and the reſt the ſpring following. Uncover the beds in cloudy or ſhowery weather; and take the mats wholly away about the end of auguſt, that the plants may be hardened againſt winter. In october or the ſpring following, the plants may be taken out of the ſeed-bed, and planted in a nurſery in rows three feet aſunder, and each plant at eighteen inches diſtance, there to remain, with the uſual care of digging and hoeing, till planted out where they are to remain, which may be done at almoſt any age, eſpecially if they are removed every two or three years[w].

Mr. Boutcher recommends the ſeeds to be well dried and kept in bags, and not to be ſown till the february following. But I have found them to riſe very readily, when ſown in a ſhady border, as ſoon as they are ripe; without any particular attention, except keeping the border clean.

All ſorts of Elms may alſo be increaſed by grafting upon the broad-leaved Wych Elm. Theſe may be raiſed from ſeed, and when they have been two years in the nurſery will be of proper ſize to receive the graft. The beginning of march is the beſt time for the work, (Mr. Hanbury ſays the laſt week in january;) and they are to be grafted only two inches above the root, ſo that the clay may be wholly covered, to guard againſt froſt. This is ſuppoſed to be a valuable improvement of the Engliſh Elm, which will thus arrive at timber many years ſooner than trees raiſed by layers, and grow to a greater ſize; the Wych Elm being the largeſt ſort, and growing the faſteſt[x]. Mr. Hanbury has given a very detailed account of the mode of performing this operation. Mr. Boutcher recommends theſe grafted trees for walks, lawns or avenues; becauſe they produce few or no ſuckers. He alſo remarks, that the variegated varieties may be grafted on the plain ones, or may be propagated from layers; but that in order to preſerve the variegation, they ſhould be planted on a poor light ſoil.

Mr. Marſhall obſerves, that an error prevails reſpecting the Elm, that it will not flouriſh in cloſe plantations. Whereas how often do we ſee two Elms ſtanding cloſe together, both equally well ſtemmed.

[w] Hanbury and Hunter. [x] Hunter and Hanbury.

Indeed

Digitized by Google

Indeed the ſhoots of the Elm will interweave with each other in a manner we ſeldom ſee in any other ſort of tree. In groups and cloſe groves we ſee them thrive abundantly. We muſt remark however, that their ſtems then running up clean, and in a great meaſure free from ſide ſhoots, the timber is different from that which is raiſed in more expoſed ſituations; where the lateral ſhoots being numerous and lopped off from time to time, the ſtems become knotty; by which means the natural tenacity, in which the peculiar excellence of Elm timber conſiſts, is conſiderably increaſed[y].

The American Elms produce plenty of ſeeds in their native country; but they ſeldom arrive freſh; the readieſt way therefore to propagate them here is from layers. They may alſo be grafted on Engliſh, Wych or Dutch ſtocks[z].

The time for felling the Elm is from november and december to february.

GENERIC CHARACTER.

Fructifications are ſmall globules diſperſed through a pellucid membranaceous or gelatinous ſubſtance, or frond. See *Woodward, in Linn. tranſ.* 3. 48.

SPECIES.

Fourteen ſpecies are enumerated in Murray's edition of Syſtema Vegetabilium. Withering has twenty-ſix britiſh ſpecies: two of them he has figured; and he has deſcribed them all. For what is new ſince Dillenius and Hudſon, we are much indebted to Mr. Stackhouſe, Major Velley, and Mr. Woodward.

U. pruniformis a ſingular ſpecies, is figured in Engliſh botany, t. 968. It grows on aquatic plants under water, and is of various ſizes from a pea to a bullace plum, of a dull olive green: the ſkin is fleſhy or gelatinous, enveloping a maſs of pale ſoft pulp, in which Linneus obſerved the minute ſeeds. He has deſcribed it well in Flora Suecica. Mr. Stackhouſe is of opinion, that neither this nor the piſiformis properly belong to this genus.

U. diaphana, figured in the ſame work, t. 263, is another ſingular production, with the appearance of pale barley-ſugar. The whole ſubſtance abounds with minute ſeeds.

U. atomaria is deſcribed by Mr. Woodward in the Tranſactions of the Linnæan Society; and figured in Engliſh Botany, t. 419. It ſpreads out like a fan, and is divided like a hand, not down to the baſe; of an olive brown. The ſeeds are very minute, of a darker colour, and diſpoſed ſomewhat irregularly in numerous tranſverſe concentric lines or ſtripes.—This is not in Withering.

U. ligulata, alſo deſcribed by Mr. Woodward, and figured in Engliſh Botany, t. 420. The fronds are five or ſix inches high, flat and branched; branches dilated ſomewhat forked with obtuſe angles; terminated and fringed with ligulate or ſtrap-ſhaped ſegments. The ſubſtance is ſemipellucid, of a brightiſh red. Seeds very minute, ſcattered ſeparately, throughout the ſubſtance of the frond; which diſtinguiſhes it from Fucus ciliatus and palmatus.

U. Lactuca is well known under the name of Oyſter-green. It is thin, pellucid, and of a fine green.

U. palmata is the Dulleſh of the Iriſh; Dills of the Scotch; Dulls or Dulſe in Northumberland. Variouſly cut like a hand expanded: it is thin, pellucid, green or reddiſh. Being ſoaked in freſh water, it is eaten either boiled or dried, and in the latter ſtate has ſomething of a violet flavour. It is ſold in the ſtreets of Dublin, being dried, and is ſaid to ſweeten the breath and kill worms. The poor in the north of Ireland eat it boiled.

U. incraſſata figured in Engliſh botany, t. 967. Gelatinous and ſlippery, graſs-green. Found on Hypnum riparium, and the ſtalks of Horſe-tail in ponds and ditches.

U. fiſtuloſa and purpuraſcens are both figured in Engliſh Botany, t. 642 and 641. and are deſcribed by Mr. Woodward in the Linnæan Tranſactions, vol. 3.

A ſufficient idea of this genus may be obtained from the above hints and refererices. Moſt of the ſpecies are maritime plants; but ſome are found in freſh waters, and a few on land. For more complete information, See Woodward in Linn. tranſ. 3. 46.

   Nauclea aculeata. *Willd. ſpec.* 1. 929.
   Ourouparia guianenſis. *Aubl. guian.* 1. 177. *t.* 68.
   Leaves ovate acute, ſtem prickly.

DESCRIPTIONS, *&c.*

1. On a more accurate examination of this plant, ſays Willdenow, I perceived that the receptacle is hairy, and the germ inferior. It differs from Nauclea parvifolia, which it reſembles very much, in having wider leaves, more ovate, and acuminate; the calyx dilated, obſcurely five-toothed, the teeth roundiſh, not ſharpiſh; the ſtamens longer than the tube of the corolla, reflexed and hanging down: and in the heads being ſubſeſſile. Native of Guinea.

2. Stem four-cornered, beſet with large oppoſite prickles, which are recurve-hooked, and compreſſed. The germ is truly inferior. Native of the foreſts of Guiana[a].

This genus is now merged in that of Nauclea: and that according to Willdenow, ſcarcely differs from Cephalanthus, except in the number of parts in the fructification.

PER. none. *Corolla* incloses the seed.

SEED one, ovate-oblong.

ESSENTIAL CHARACTER.

Cal. many-valved. *Spikelet* ovate keeled.

SPECIES.

1. Uniola paniculata.
   Lin. spec. 103. *Reich.* 1. 195. *Willd.* 1. 406. *hort. cliff.* 23. *Gron. virg.* 136.
   Gramen myloicophorum oxyphyllon carolinianum. *Pluk. phyt. t.* 32. *f.* 6. *Catesb. car.* 1. *t.* 32.
   Panicled, spikelets ovate.
2. Uniola mucronata.
   Lin. spec. 104. *Reich.* 1. 196. *Willd.* 1. 406.
   Spike distich, spikelets ovate, calyxes somewhat awned.
3. Uniola spicata.
   Lin. spec. 104. *Reich.* 1. 196. *Willd.* 1. 406.
   Gramen parvum maritimum spicatum, foliis angustis rigidis. *Clayt.* 507.
   Subspiked, leaves rolled in rigid.

DESCRIPTIONS, &c.

1. Native of Virginia and Carolina. Called there Sea-side Oat.

2. Culm a foot high, even. Leaves narrow, smooth, with striated sheaths. Spike composed of eleven or twelve alternate, distich, subsessile, ovate, smooth flowers, each having seven florets. Calyx mucronate almost into an awn. Native of the East Indies.

3. Culm a span high, with alternate rigid leaves, rolled in and mucronate. Panicle very small, squeezed so close that there is scarcely any sign of pedicels, all directed one way. Calyx and glumes keeled, with four florets. Native of North America on the coast[b].

UNIOLA. See *Briza* and *Poa*.

UNONA *(So named from the union of the anthers upon the germ.)*
Lin. gen. Schreb. n. 947. *suppl.* 44. *Juss.* 283.
Class. 13. 7. Polyandria Polygynia.
Nat. Order of *Coadunatæ*. *Anonæ* Juss.

GENERIC CHARACTER.

CAL. *Perianth* three-leaved, very small, acute, pressed close.

COR. *Petals* six, lanceolate, sessile, gibbous at the base on the outside, at the same time excavated within into the shape of a pitcher.

STAM. *Filaments* none. *Anthers* very numerous, oblong, collected into a ball within the pitcher of the corolla.

PIST. *Germs* many, sessile. *Styles* about ten, bristle-shaped, approximating, rather longer than the anthers. *Stigma.*

PER. *Berries* many, pedicelled, ovate, gibbous, jointed like a necklace.

SEEDS two or three, ovate, very smooth, one above the other.

OBS. *Very nearly allied to Xylopia and Annona, Linn. also to Uvaria, to which it is united by Swartz. But Willdenow keeps them separate.*

ESSENTIAL CHARACTER.

Cal. three-leaved. *Pet.* 6. *Berries* two or three-seeded, jointed like a necklace.

SPECIES.

1. Unona discreta.
   Lin. syst. 509. *Willd.* 2. 1271. *suppl.* 270. *Vahl. symb.* 2. 63.
   Leaves lanceolate silky beneath.
2. Unona tomentosa.
   Lin. spec. ed. Willd. 2. 1271.
   Desmos cochinchinensis. *Lour. cochinch.* 352. *ed. Willd.* 431.
   Leaves lanceolate tomentose.
3. Unona discolor.
   Lin. spec. ed. Willd. 2. 1271. *Vahl. symb.* 2. 63. *t.* 36.
   Desmos chinensis. *Lour. cochinch.* 352. *ed. Will.* 431.
   Leaves ovate-oblong smooth on both sides.
4. Unona concolor.
   Lin. spec. ed. Willd. 2. 1271.
   Uvaria zeylanica. *Aubl. guian.* 1. 605. *t.* 243.
   Leaves oblong attuminate smooth on both sides concolor, peduncles two-flowered.

DESCRIPTIONS, &c.

1. This is a tree with wand-like narrow flexile branches. Leaves two-faced alternate resembling those of the Privet, smooth quite entire a finger's length, on very short petioles. Pedicels of the berries within the corolla umbelled. Flower of Annona, but the fruit is different purple sapid aromatic, which distinguishes the genus as in Theobroma and Abroma[c].

Branches pubescent. Leaves an inch and half long, very much attenuated narrow resembling those of the Willow scarcely petioled[d].

Native of Surinam, where it was found by Dalberg.

2. This is a shrub five feet in height, with an upright stem, and weak reclining branches. Leaves alternate, quite entire, petioled. Flowers yellow-green, terminating, solitary, hanging down by a very long peduncle. Berries red-green, subsessile, adhering to a hemispherical receptacle. Native of Cochinchina[e].

Father Loureiro has named this *Desmos*, from the berries being joined like the links of a chain.

3. This is a tree with round purplish smooth branches, scarcely villose at the end. Leaves alternate, three inches long, and two inches wide, rounded at the base a little acuminate at the tip, bluntish, quite entire, membranaceous, nerved, somewhat veined and glaucous underneath, also silky when young. Petioles very short, villose. Peduncles lateral, below the leaves, an inch and half long, a little thicker at top, having a blunt lanceolate leaflet in the middle, one-flowered, solitary. Calyx-leaves ovate, villose. Petals coriaceous, tomentose, lanceolate; the three inner ones narrower. Fruits pedicelled, umbelled, two or three-jointed: joints globular, a little smaller than a pea, the end ones mucronate and smooth. Receptacle globular, the size of a pea, somewhat villose. Native of the East Indies, where it was found by Koenig[f].

Willdenow suspects that the Desmos chinensis, which Loureiro found near Canton, may be the same plant. —He describes it as an upright branching shrub, six feet high, with ovate-lanceolate smooth leaves, and the corolla spreading; in other respects agreeing with the preceding, of which he thinks it may be a variety.

4. Native of Guiana.

UNXIA. (*From* ungo, unxi, *to smear or anoint.*)
Lin. gen. Schreb. 1288. *suppl.* 56. *Juss.* 186.
Class. 19. 2. Syngenesia Polygamia Superflua.
Nat. Order of *Compositæ Discoideæ*. *Corymbiferæ* Juss.

GENERIC CHARACTER.

CAL. *Common* roundish, five-leaved: *leaflets* ovate.

COR. *Compound*, radiate: *ray* indistinct. *Corollets hermaphrodite* five in the disk; *Females* as many in the ray.

Proper to the *hermaphrodites* funnel-form, five-cleft; to the *females* ovate, small.

STAM. in the Hermaphrodites. *Filaments* five. *Anther* cylindric, tubular.

PIST. to each. *Germ* ovate. *Style* simple. *Stigma* bifid.

PER. none. *Calyx* unchanged.

SEEDS to all ovate, hard, naked.

REC. naked.

ESSENTIAL CHARACTER.

Cal. five-leaved, leaflets ovate. *Florets* of both disk and ray five. *Seed-down* none. *Recept.* naked.

SPECIES.

1. Unxia camphorata.
   Lin. syst. 774. *suppl.* 368. *Gærtn. fruct.* 2. 421.

DESCRIPTION, &c.

Stem herbaceous, filiform, dichotomous, two feet high. Leaves opposite at the divisions, sessile, lanceolate, five-nerved, hirsute, soft. Flowers solitary from the divisions, subpeduncled, the size of a pea. Ray of the corolla spreading small. The plant has a strong

[b] Linn. spec. [c] Linn. suppl. [d] Vahl. [e] Loureiro. [f] Vahl.

smell

ſmell of plaſter or Camphor. A decoction of it in water is eſteemed an admirable ſudorific, and of great efficacy in the obſtinate Lumbago of the inhabitants of Surinam. The dried herb is uſed externally, when the tranſpiration is ſuppoſed to be impeded. Native of Surinam, where it is called Camphor-plant. Communicated by Dalberg[g]. Gærtner remarks, that if the androgynous florets are barren, as there is reaſon to ſuſpect from what Juſſieu has ſaid, this genus ought to be placed next to Milleria.

VOCHY. See *Cucullaria*.]

VOLKAMERIA. (*So named by Linneus in memory of John George Volkamer, phyſician at Nurimberg. Author of* Flora Noribergenſis, 1700.)

Lin. gen. n. 788. *Reich. n.* 851. *Schreb. n.* 1056. *Gærtn. t.* 56. *Juſſ.* 107. Douglaſſia *Rel. Houſt. t.* 13.

Claſſ. 14. 2. Didynamia Angioſpermia.

Nat. Order of *Perſonatæ*. *Vitices* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, turbinate, five-cleft, nearly equal, acute.

COR. monopetalous, ringent: *tube* cylindric, twice as long as the calyx: *border* five-parted, nearly equal, flat: *ſegments* reflexed to one ſide, gaping chiefly on the upper ſide

STAM. *Filaments* four, filiform, very long, on the gaping ſide of the corolla. *Anthers* ſimple.

PIST. *Germ* four-cornered. *Style* filiform, length of the ſtamens. *Stigma* bifid; one of the ſegments acute, the other indiſtinct.

PER. *Berry* (Drupe) roundiſh two-celled, four-grooved.

SEED. *Nut* ſolitary, two-celled, grooved.

OBS. *The fruit is called by ſome a* Berry; *by others a* Drupe; *and by others again a* Capſule.

ESSENTIAL CHARACTER.

Cal. five-cleft. *Cor.* ſegments directed the ſame way. *Drupe* two-ſeeded. *Nuts* two-celled.

   Leaves cordate pubeſcent toothletted, panicle terminating divaricate on coloured peduncles.

DESCRIPTIONS, &c.

1. This is a ſhrub five or ſix feet high, branched; upright, the whole loaded with white flowers, which have no ſcent. Stamens moſt commonly five, but ſometimes ſix, purple. Fruit brown[h]. Gærtner deſcribes it to be a roundiſh juiceleſs berry, ſwelling into four little bumps at top, four-grooved, ſhining, conſiſting of two parts, and opening two ways. Stones (or nuts) two, cartilaginous, obcordate, convex on one ſide, marked with a groove along the middle, flat on the other, ſmoothiſh, two-celled. One ſeed in each, ovate-oblong, convex on one ſide, ſomewhat angular on the other, faſtened to the baſe of the cells.—According to Houſtoun, the fruit is roundiſh, divided into two parts, each of which contains a ſhell, having two ſeeds in it, contained in as many cavities.]

Miller ſays, that it riſes in the Weſt Indies to the height of twenty feet, (but Jacquin and Browne aſſign only five or ſix feet to it.) The branches are pliable and much diffuſed, covered with a light ſmooth bark. Leaves oppoſite, lucid. The flowers come out from the ſide of the ſtalk, five or ſix on the ſame peduncle, almoſt in form of an umbel, in ſhape ſomewhat like thoſe of the common Jaſmine, but with a curved tube.

[According to Sir Hans Sloane it has ſeveral ſmall ſtems, ten or twelve feet long, inclining their heads downwards and covered with a whitiſh-gray ſmooth bark. Towards the ends of the branches are many ſhort crooked prickles, oppoſite at half an inch diſtance; and many leaves likewiſe oppoſite, two inches long, and half an inch broad in the middle, on petioles half an inch in length.

Native of the Weſt Indies. Browne ſays it is one of the moſt common plants in the Lowlands of Jamaica, in a dry gravelly ſoil; and is abundant in moſt of the other ſugar iſlands.—It was cultivated in 1739 by Mr. Miller[i]. It is ſingular that he has omitted this and the inermis in the later folio editions of his Dictionary, and yet has inſerted them in the Abridgments in quarto.

2. This differs from the inermis which it reſembles very much, in having oblong-lanceolate leaves, the branches, &c. hirſute, the tube of the corolla only three times (not ſix times) as long as the calyx, the filaments white not purple, the anthers brown not violet. Native of the iſland of Mauritius.

3. Leaves oppoſite, annual, petioled, bluntiſh. Peduncles from the upper axils, oppoſite, ſolitary, a little ſhorter than the leaf, three-cleft, three-flowered, more ſeldom ſimple and one-flowered. It ſo reſembles the firſt, that if that were deprived of its ſpines, they would ſcarcely be diſtinguiſhed[k].]

This riſes higher than the firſt ſort, the ſtem and branches are ſtronger and grow more erect; the bark is very white, the leaves frequently grow round the branches in cluſters or whorls. Flowers on long axillary peduncles, ſupporting ſeveral flowers, which generally ſtand erect.

[Gærtner makes this ſhrub a Clerodendrum, and deſcribes the fruit as a turbinate berry, ſwelling into four bumps at top, four-parted, and the parts ſeparable when ripe. Fleſh thickiſh, corky, growing to the back of the parts or ſhells; which are coriaceous cruſtaceous, whitiſh, remarkably acuminated downwards, roundiſh-gibbous at top, one-celled. Seeds correſponding with the cavity of the ſhells or ſtones.

[g] Linn. ſuppl.

[h] Jacquin. [i] Hort. kew. [k] Linn. zeyl.

Digitized by Google

Native of the Eaſt Indies. Cultivated in 1692 at the Royal Garden, Hampton Court[l].

Willdenow informs us, that he has ſeen a variety with ſmaller and very blunt leaves.

4. Branches bluntly quadrangular hoary ſmooth, tubercled with the blunt prominent rudiments of the petioles. Leaves oppoſite, remote, oblong-ovate, acuminate with a blunt mucronate point, quite entire, veined, ſomewhat ſcabrous on both ſides with diſtant hairs. Flowers white in a terminating head, which is ſhortly peduncled and five-flowered. Calyx bell-ſhaped, with a three-parted border, the ſegments very large, oblong, leafy, mucronate, netted-veined, ciliate. Tube of the corolla filiform two inches long and more; border five-parted unequal, with oblong blunt ſegments. The ſtamens reach very far beyond the flower. Fruit unknown. Native of Guinea[m].

5. Branches roundiſh. Leaves naked on both ſides. Panicle brachiate. Berries compoſed of four. Calyxes bell-ſhaped, undivided, ſcarcely toothed. Native of the Eaſt Indies[n].

6. This is a ſcandent tree, with very long flexuoſe four-cornered branches, tomentoſe at the top. Leaves large, very ſmooth, oppoſite, obtuſe. Panicle tomentoſe. Flowers not long as in V. inermis. Calyxes blunt tomentoſe. Capſule oblong, conical. It climbs up the higheſt trees, crowning them with its ſnow-white flowers. Native of the vaſt foreſts of Ceylon[o].

7. This is a vaſt lofty tree, ſmooth and branched. Branches compreſſed, panicled at the end. Leaves alternate, deeply cordate, acuminate and veined, paler and ſmooth underneath; the lower ones a ſpan wide and a foot long, the upper ones gradually leſs and blunter. Petioles to the larger leaves a ſpan long, in the ſmaller ones half an inch. Flowers at the end of the branchlets in racemes. Bractes under each peduncle, awl-ſhaped, ſolitary, ſhorter than the peduncle. Peduncle ſimple, one-flowered, erect. Calyx browniſh, five-parted, with the ſegments divaricate at the baſe, concave, lanceolate, awned. Tube of the corolla purple: border ſhorter than the tube. Capſule ovate, the ſize of a plum, four-valved, two-celled, opening tranſverſely. Native of Japan[p].

A ſmall tree is cultivated in ſome of the European gardens, under the name of Volkameria japonica, with double flowers, the plant reſembling that which is figured in Kæmpfer's ſelect plates edited by Sir Joſeph Banks. On account of the flowers being double, it cannot with certainty be reduced to its proper genus; but it differs in many reſpects from Volkameria japonica[q].

8. Leaves oppoſite, deeply cordate, roundiſh, ſhortly acuminate, very finely and remotely toothletted. Panicle wide, compoſed of oppoſite two-parted racemes. The peduncles of the whole panicle, the floral leaves, the calyxes and corollas ſcarlet. Drupe black, the ſize of a Currant, ſhorter than the calyx, two-celled. Nuts two-celled. Native of China and Japan[r].]

PROPAGATION AND CULTURE.

The plants are propagated in Europe by cuttings, which readily put out roots, when they are planted in pots, and plunged into a moderate hot-bed, covering them cloſe with hand glaſſes. The cuttings may be planted any time from the middle of may to the end of july when they have put out roots; ſeparate the plants carefully and put each into a ſeparate ſmall pot: plunge the pots into a gentle hot-bed, till they get freſh roots: then inure them to the open air, if the weather be warm; and continue them abroad in a ſheltered ſituation until the nights begin to be cold; when they muſt be removed into the houſe. There they require ſome warmth; they ſhould be placed therefore in a moderate ſtove. In too much heat they are ſubject to ſhoot and grow weak; but they will not ſurvive the winter in a common greenhouſe.

U. monopetala. *Lour. cochinch. ed. Willd.* 508?

Leaves one-glanded ſomewhat rhombed toothed.]

DESCRIPTIONS, &c.

1. This riſes with an upright ſtalk upwards of two feet high, which becomes woody towards the autumn. It ſends out a few ſide branches which are taper, ſtiff, and have a dark-green bark. Leaves about two inches and a quarter broad, dark green above and pale green beneath, upon pretty long footſtalks. Flowers axillary, ſolitary, ſeſſile, ſhaped like thoſe of the Mallow, but ſmall and of a deep bluſh colour. Capſules roundiſh, armed with prickly hairs.

[Stem round, hairy. Leaves three-lobed ſerrate, hairy, alternate [c]. Loureiro remarks, that Rumphius's plant has the leaves laciniated. The leaves have a glandular pore on three intermediate ribs underneath [d]. Capſules five, united into a ſubglobular rounded-pentagon fruit, they are coriaceous; on one ſide convex, and echinated with hooked briſtles; on the other wedgeform-angular, unarmed, one-celled, not opening. Seed one in each cell, kidney-ſhaped, very thick on the back, very finely ſtriated, aſh-coloured. In the centre of the fruit is a ſubulate-pentagon receptacle; and each ſeed is faſtened by a very ſhort umbilical cord reaching from the middle of the central angle to the middle of the ſeed [e].

Native of China and Cochinchina. Forſter ſays, every where within the tropics. Cultivated by James Sherard, M. D. in 1732. It flowers here in july and auguſt [x]. Dillenius reports, that the ſeeds came from China by an Oſtend ſhip, and were communicated by Egmont van Nyenborg, a noble Fleming.

2. Leaves underneath whitiſh, tomentoſe, netted-nerved, all toothed, the uppermoſt lanceolate. Native of South America.

3. Leaves unequally toothed; the lobes of the lower leaves angular. It differs from the preceding, in having the ſtem rough with hairs, not tomentoſe, and all the leaves three-lobed. Native of the iſlands of Mauritius and Bourbon [y].

4. Stem fruteſcent, round, ſcarcely ſcabrous. Leaves petioled, half-three-lobed, with the ſinuſes obtuſe, not hollowed out roundiſh, ſerrate except at the baſe, bluntiſh, the middle lobe a little larger than the others, the outer ones more diſtant: under the nap is a ſingle nectareous pore, at the baſe of the middle nerve on the lower ſurface. Calyx and fruit as in the other ſpecies, but the corolla ſmaller. Obſerved in Surinam by Dalberg [z]: and in Barbadoes by Sloane. Swartz is of opinion, that it is ſcarcely more than a variety of the next ſpecies which frequently varies with the upper leaves trifid [a].]

5. Mr. Miller makes two ſpecies of this, aculeata, n. 2. and ſinuata, n. 3. The aculeata, he ſays, riſes with a woody ſtalk three feet high, dividing into four or five branches, and has a grayiſh bark. Lower leaves angular, an inch and half long, and about the ſame breadth: thoſe above are cut ſome into three, others into five angular obtuſe lobes: they are dark green above, but pale beneath, ſharply ſerrate, on long footſtalks. Flowers axillary, ſolitary, larger than thoſe of the firſt ſpecies; the petals narrower at their baſe, with deep-red bottoms. U. ſinuata has hairy ſtalks, dividing into many branches, and riſing about two feet high. Leaves oblong, divided into three obtuſe lobes to the midrib: lobes indented in ſeveral parts, light green on both ſides and hairy. Flowers axillary, ſolitary, ſeſſile, pale bluſh-coloured with a deep-red bottom.

[Stem ſuffruticoſe, upright, three feet high, with aſcending branches. Leaves ſinuate-palmate with obtuſe ſinuſes, ſerrate, rough, alternate, petioled, having a ſingle glandular pore on the middle rib underneath. Flowers roſe-coloured, ſmall, ſubſplitary, axillary: both calyxes five-cleft. Arils five, ovate, echinate [b].

Stem ſhrubby from one to two feet high, branched, upright, round, pubeſcent. Branches nearly ſimple, erect, round. Leaves petioled, alternate: lower roundiſh, five-cornered, ſubſerrate: middle cordate-five-cornered, with the corners blunt, ſerrate-toothletted: upper ſinuate, five-lobed, tooth-ſinuate, nerved, hirſute, hoary underneath, having a glandular pore in the middle nerve. Petioles longiſh, round, erect, pubeſcent. Flowers axillary, on very ſhort peduncles, blood-red, the ſame ſize as in Malva ſylveſtris. Outer calyx five-leaved, linear, erect, blunt: inner five-parted, with erect lanceolate ſegments the length of the outer. Petals five, contiguous at the baſe, oblong, obtuſe, entire. Capſules five, cloſe, connected, echinate. Seeds oblong, compreſſed, even [c].

Native of the Eaſt Indies. Cultivated in 1759, by Mr. Miller [d]. Loureiro ſays it grows wild in Cochinchina. According to Swartz, it ought not to be ſeparated from the Eaſt Indian ſpecies, and is found in Jamaica, in dry paſtures. Accordingly he gives the ſynonym of Sloane, which may be found here under the preceding ſpecies. Alſo the ſecond Urena of Browne, which he ſays is remarkable for the lobed form of the leaves, and the compreſſed make of its rugged capſules.

Willdenow thinks that the ſinuata of Swartz is a different ſpecies from this. I have therefore kept his deſcription diſtinct, and ſhould rather refer it to the preceding.

6. The whole plant is rough-haired. It has the appearance of the preceding, but the leaves are one-glanded, and the lobes acuminate, gaſh-toothed. Native of the iſland of Mauritius [e].

7. Stem fruteſcent, procumbent, creeping, very much branched. Leaves the ſame ſize as in Origanum, ſubcordate, entire not lobed, even, ſharply ſerrate. Flowers larger than the leaves. Found in China by Oſbeck [f]; who ſays that it has a very low ſtem, with the boughs hanging round about on the ground.

According to Loureiro, it is found in ſandy places in Cochinchina as well as China. He deſcribes the

Digitized by Google

ſtem as ſuffruticoſe, three feet high, procumbent, round, reddiſh, branched. The leaves haſtate, unequally and deeply ſerrate, rough, alternate. Flowers ſaffron-coloured, axillary, cluſtered. Both calyxes five-cleft. Stamens ten. Capſule round, echinate, four-celled.

β. Lower leaves roundiſh-ovate, acute, angular, toothed, the reſt roundiſh-rhombed, toothed, except the uppermoſt which are lanceolate. Outer calyx longer than the inner. Native of Braſil *.

Loureiro has a Cochinchineſe ſpecies, which he names U. monopetala. Willdenow ſuſpects that it may be the ſame with the viminea of Cavanilles. Loureiro thus deſcribes it. Stem ſuffruticoſe, two feet high, erect, branched. Leaves ovate-lanceolate, entire, ſerrate, veined, tomentoſe, alternate. Flowers violet, axillary, ſolitary. Outer calyx five-leaved, ſhorter. Corolla one-petalled; tube equal to the calyx; border ſpreading, five-parted, with the upper ſegment larger and emarginate. Capſule roundiſh, muricate, five-celled.

He has another ſpecies, which he entitles U. polyflora, found near Canton in China. But Willdenow ſuſpects this to belong to the genus Malachra.]

PROPAGATION AND CULTURE.

Theſe plants are propagated by ſeeds, which ſhould be ſown on a hot-bed early in the ſpring; and when the plants are fit to remove, they ſhould be tranſplanted into pots, and plunged into a freſh hot-bed to bring them forward, and afterward they muſt be treated in the ſame manner as has been directed for the tender ſorts of Hibiſcus. If the plants are brought forward in the ſpring, and afterward placed in the ſtove, or under a deep frame, they will ripen ſeeds the firſt ſeaſon; but if they ſhould not, they may be preſerved through the winter in the ſtove, and will ripen their ſeeds the following ſeaſon, after which the plants ſeldom continue.

Lin. ſyſt. 851. *Thunb. jap.* 70.
Leaves alternate cordate rough-haired, globules ſeſſile.

DESCRIPTIONS, &c.

1. Stem from eighteen inches to two feet in height. Leaves on long footſtalks, varying in ſhape, moſt frequently cordate, but often ovate, ſurrounded with very deep ſerratures except near the inſertion of the footſtalk, where they are entire. Flowers axillary, peduncled; thoſe of the males branched, longer and more ſlender than thoſe of the females, which are ſimple, about half an inch long, each bearing one ball, three or four lines in diameter, when in ſeed pendent. The whole plant is thick ſet with ſtinging hairs, more pungent than the two common Nettles [h].

Dr. Smith ſays it is an annual of very luxuriant growth; the ſtem obtuſely angular, often purple. Leaves ovate, ſometimes heart-ſhaped, pointed, very ſtrongly ſerrate, paler beneath. Flower-ſtalks moſtly in pairs, thoſe of the male flowers panicled. The ſuppoſed nectary is an obſolete concave tubercle, which ſeems rather to be the rudiment of a germ, and the ſtamens ſurround it. The calyx is of four equal leaves: whereas that of the female flowers, (which are in a round head), has two hemiſpherical valves cloſely embracing the germ, and holding the ſeed till it is quite ripe. Seed dark-brown, highly poliſhed.

Dr. Smith farther remarks, that his ſpecimens ſeem intermediate between thoſe of the pilulifera and balearica in the Linnean herbarium, and notwithſtanding the opinion of Profeſſor Murray, he believes theſe ſpecies not to be diſtinct.

Mr. Woodward alſo ſuppoſes, that our ſpecies includes both. The only ſpecific difference given by Linneus conſiſts in the words *ovatis* and *cordatis*: but from frequent obſervations, he can ſee no reaſon to think this difference in the leaves to be any thing more than accident and ſcarcely worthy to be noticed as varieties. If the plant grows very cloſe to a wall, it is frequently taller and more ſlender, the leaves are then generally ſmall and ovate, and the ſerratures very ſhallow: when more diſtant from the wall, the plant is ſhorter and ſtronger, the leaves larger and heart-ſhaped, and the ſerratures very deep. He cannot perceive any difference in the fruitſtalks or balls of flowers.

Native of the ſouth of Europe, the eaſt coaſt of England, and about Tunis in Barbary. Ray found it plentifully at Yarmouth in Norfolk near the quay, as alſo about Aldborough in Suffolk, and elſewhere on that coaſt. It has ſince been obſerved about Loweſtoft and Bungay in Suffolk. Parkinſon ſays it has been found growing time out of mind at Lidde by Romney in Kent, and in the ſtreets of Romney itſelf. He conjectures, that the Roman ſoldiers, who came with Julius Cæſar, ſowed it there. Mr. Dillwyn informs us, that it is extinct at old Romney, but that it ſtill grows plentifully a little ſouth of Lyd churchyard [i]. Gerarde affirms that it is a ſtranger to England, and Johnſon does not correct the error. It is commonly found among rubbiſh and ſtones, and flowers in june and july.

2. Linneus allows this to be too nearly allied to the preceding, and thinks it may be a variety or a daughter of that. The leaves are cordate and wrinkled; Murray remarks, that the leaves at the baſe are ſo oblique, that they are more prominent on one ſide; that they are entire towards the baſe and top, but in other parts ſerrate with obtuſe ſinuſes; and that in thoſe which are far advanced the margin is contracted, ſo that they ap-

[h] Woodw. Mſſ.

[i] Linn. tranſ. 6. 182.

pear

pear to be convex. In his ſpecimens, he ſays, ſome of the leaves are ovate, others cordate; ſome of the ſtems and petioles purple, others not. He had the ſeeds from Oeder, who doubted whether it is a diſtinct ſpecies. They ſeem to compare it with U. Dodartii, which is diſtinct: but it is probably a variety of U. pilulifora, as Linneus ſuggeſted, and as Woodward and Smith aſſert.] Miller ſays, it differs from that in having narrower leaves and globular katkins; but being ſomewhat like it, is not often diſtinguiſhed from it. It was diſcovered in the Balearic Iſlands (Majorca and Minorca) by Mr. Salvadore, an apothecary in Barcelona, who ſent the ſeeds to many botanic gardens. By miſtake, Linneus has ſet it down as a native of India, though he names it balearica.

3. Root annual. Stems much more ſlender than thoſe of the former, and ſeldom branching. Leaves upon very ſlender footſtalks, for the moſt part entire. Male and female flowers axillary, ſhaped like thoſe of the former. The whole plant is armed with ſtinging hairs.

[Linneus ſays, it is too nearly allied to the two preceding, the male flowers being alſo placed below; but the leaves are ſcarcely ſerrate. According to Dr. Smith, it appears different enough from both.

Native of the ſouth of Europe (Miller ſays Spain and Italy.) Cultivated here in 1713. It flowers in july and auguſt [k].

4. Root fibrous. Stem the height of a finger, ſimple. Leaves three-nerved, naked, ſerrate, on petioles almoſt a finger's length. Racemes axillary, two-parted, or even dichotomous; length of the petioles [l]: or ſhorter according to Gronovius. Native of Canada, in watery places.

5. Root ſmall, brown, fibrous. Stem a foot and half high. Leaves four inches long, and three inches broad in the middle, rough, of a freſh green colour, a little indented about the edges, having three ribs running from the end of the footſtalk, with ſeveral tranſverſe ones. Flowers at top in a bunch together, browniſh, very ſmall, muſcoſe, reticulated [m].

It varies from a foot in height to four feet, with leaves to a ſpan in length, with ſmaller racemes to very large diffuſed ones, often bigger than the leaves, and white, green and red flowers; both ſexes on the ſame plant. Native of the Weſt Indies in ſhady moiſtiſh places: on dry ground it is a lower plant. It flowers in the middle of ſummer [n].

6. Stem a foot high, erect, tender, hairy, eſpecially towards the top, branched at bottom. Branches ſhorter than the ſtem. Leaves bluntly ſerrate, with the laſt ſerrature elongated, quite entire at the baſe, ſomewhat hairy, paler underneath, an inch long, on a filiform hairy petiole, the length of the leaf. Flowers in a ſort of whorl, hairy.

7. Native of Jamaica.

8. The ſmall Nettle is diſtinguiſhed from the great one (U. dioica) by its humbler ſize, being ſcarcely one-third of the height of that; its annual, white, fibrous root, its brighter green colour, and elliptical leaves, much ſmaller and rounder, three or five-nerved and ſcabrous. The ſtalks are much branched, the ſtipules ſmall and reflexed, the racemes androgynous, nearly ſimple, commonly ſhorter than the petioles. Female calyx ovate, compreſſed a little [o].

Native of Europe, Siberia and Barbary. It is a common weed in cultivated ground, eſpecially on a light ſoil, and is a great peſt of gardens, where it often ſeeds abundantly twice in one ſeaſon.

9. 10. Natives of Hiſpaniola.

11. 12. Natives of Jamaica [p].

13. Root perennial, creeping, tough, yellowiſh, ſending down from the joints ſome pretty large fibres. Stems many, three feet (or from two to four feet) high, upright very little branched, bluntly quadrangular, each ſide furrowed. The whole plant is pubeſcent, and clothed with ſtinging briſtles. Leaves cordate-ovate, acuminate, widely ſerrate, petioled; the upper ſide wrinkled and veiny. Stipules in fours, ovate, acute, erect, membranaceous, (ſpreading, linear, bluntiſh, the under ſide compreſſed and channelled, *Curtis*). Racemes in pairs on each ſide, or four together at a joint, branching and ſpreading very much, many-flowered. Flowers diſperſed in ſmall cluſters, commonly dioecious, but often monoecious [q]. The ſeed is ſmall, of an attenuated ovate ſhape, compreſſed like a lens, of a pale whitiſh colour; the two calyx-leaves ſerve it inſtead of a pericarp [r].

The great common Stinging-Nettle grows all over Europe, in Barbary, Siberia and Japan, in hedges, neglected fields, gardens and paſtures, flowering from june to ſeptember.

In this numerous genus all the ſpecies do not ſting, as the three ſorts which are natives of this country are well known to do. The ſmall projecting prickles or briſtles with which they are covered are tubular, and ſtand on a bag filled with a poiſonous juice; they are perforated at the point, and when they are gently preſſed vertically, the preſſure at once forces the poiſon to aſcend the tube, and enables the point to lodge it in the ſkin.

Nettle-tops in the ſpring are gathered by many of the poorer people as a pot-herb, and are put into diet-drinks to purify the blood. In Arran and other Scottiſh Iſles a rennet is made of a ſtrong decoction of Nettles; a quart of ſalt is put to three pints of the decoction and boiled up for uſe: a common ſpoonful of this liquor will coagulate a large bowl of milk very readily and agreeably [s].

The ſtalk of the Nettle is found to have a texture ſomewhat like that of Hemp, and to be capable of being manufactured into cloth, ropes and paper.

The Nettle is refuſed by quadrupeds in general, except the Aſs. Cows however will eat it, when it is cut and lies to wither a little. Haller ſays it affords excellent food for milch kine, and that it has even been cultivated advantageouſly in Sweden, for that purpoſe. The leaves are chopped ſmall to mix with the food of young turkeys and other poultry. The nettle is the only food of the caterpillars of three of our moſt beautiful butterflies, *Atalanta*, *Paphia*, and *Urticæ*; the principal food of the *Io*; and the occaſional food of the *Comma album*: the caterpillars alſo of the *urticata* and *verticalis* moths feed on it: a great number of other indiſcriminate feeders devour its foliage; and the baſe of the leaves in autumn are frequently diſfigured by tubercles, which contain ſmall maggots, probably producing Muſca Urticæ [t].

As a ſtyptic the Nettle was formerly much uſed; and we are told of various hæmorrhagic affections in which it was ſucceſsfully employed. Dr. Withering ſays, a leaf put upon the tongue, and then preſſed againſt the roof of the mouth, is efficacious in ſtopping a bleeding at the noſe. It is alſo ſaid to manifeſt a diuretic character, and to be uſeful in calculous complaints, ſcurvy, gout, jaundice, &c. But theſe accounts have now little credit.

The ſharp briſtles readily entering the ſkin, and thereby producing conſiderable irritation and inflammation, have been employed as a rubifacient, a practice which was termed urtication, and found of advantage, in reſtoring excitement in paralytic limbs, or in other caſes of torpor or lethargy [u].

The juice of the Dock, or even of the Nettle plant itſelf, is a ſpeedy remedy for the ſting [v].

14. This in habit and various circumſtances is ſufficiently allied to the preceding; but it differs at firſt ſight, in having the racemes a ſpan long, quite ſimple, erect; the leaves much wider; and the ſtipules ovate not linear-lanceolate as in the common Nettle. If it be a variety, which it ſcarcely ſeems to be, it is certainly very worthy of remark [x].

Vahl found it growing very abundantly about Tunis, where he never obſerved our common Nettle. Haſſelquiſt found it in Egypt, and remarks, that the Arabians call it Curcis. It is in Forſkahl's catalogue of Arabian plants.

15. This alſo has the appearance of the common Nettle, but the hairs are ſcattered thinly over it. Stem branched. Leaves ovate, toothed, on long petioles. Bractes lanceolate, acute. Flowers monoecious: the

males from the top of the branches in ſpikes, which are in pairs, axillary, filiform, ſimple, directed one way, ſeſſile on a widiſh rachis, membranaceous on each ſide: the females below collected into ſhort axillary racemelets. Barbary near la Calle [a].

16. 17. Natives of Hiſpaniola [b].]

18. Root perennial. Stems five or ſix feet high. Leaves oblong, deeply cut into three lobes, which are acutely indented on their edges; and placed on long petioles. Flowers axillary in long cylindrical katkins: males on the lower part, females on the upper. Seeds like thoſe of flax, incloſed in the three-cornered calyx. The ſtem and leaves are armed with ſtinging hairs.

Native of Siberia, whence the ſeeds were brought to the Imperial garden at Peterſburgh, and diſperſed to moſt parts of Europe. It flowers in july, and the ſeeds ripen in autumn. [Cultivated by Mr. Miller in 1752.

19. Native of Hudſon's Bay. Introduced by the Hudſon's Bay Company, in 1782. It flowers from june to auguſt [c].

20. Stem ſhrubby, rugged, round, ſtiffiſh, nearly upright: branches oppoſite, horizontal, diffuſed. Leaves petioled, nodding, rugged eſpecially on the edge. Two ſtipules on each ſide. Flowers axillary, ſeſſile: males in pairs, with a four-parted calyx, and four white ſtamens: a female flower ſits cloſe to the males, with one long pubeſcent white ſtyle. Fruit ovate, emarginate, grooved with eight ſwellings. Seed very ſmooth, ovate, black with a white baſe. It is a little evergreen plant. From its male flowers it is an Urtica; but from its female flowers and fruit, a Parietaria: therefore between both [d]. Native of Ceylon.

21. Native of Jamaica.

22. Native of Hiſpaniola [e].

23. Roots numerous, long thready. Stem herbaceous, ſuffruteſcent at bottom, from two to eight feet in height, branching very much, erect, angular, four-ſided, ſtriated. Branches long, ſubdivided, quadrangular, red: branchlets filiform, oppoſite to the leaves, looſe, ſmooth. Leaves three-nerved, veined, ciliate at the edge. Leaflets of the ſame ſhape, but twice or four times ſmaller. Petioles long, ſpreading, red. Racemes axillary, terminating, oppoſite. Peduncles longer than the petioles, filiform, coloured, four-ſided, erect, ſmooth. Flowers dioecious: females very ſmall on panicled racemelets. Seed very ſmall, black and ſhining. Native of the Weſt Indies, on high mountains; flowering all the year [f].

24. 25. Natives of Jamaica [g].

26. Native of South America [h].

27. 28. Natives of Jamaica.

29. Native of Hiſpaniola.

30. 31. 32. Natives of Jamaica.

33. Native of Hiſpaniola.

34. Native of Jamaica [i].

35. Stem round, purple, ſmooth. Branches filiform, hiſpid at the baſe. Leaves three-nerved, rugged, on capillary petioles ſhorter than the leaf. Flowers in axillary capillary ſolitary ſpikes, a finger's length, interrupted.

Native of Japan, near Nagaſaki and in the mountains of Koſido; flowering from july to october.

36. Stem four-cornered, grooved, purpliſh. The whole plant very finely pubeſcent. Leaves not at all cordate, acute, deeply and doubly gaſh-ſerrate, three-nerved, hairy and ſcabrous, on petioles ſhorter than the leaf. Flowers axillary panicled. Native of Japan, in the ſame places [k].

37. Stem herbaceous, a foot high, erect. Leaves rhomb-ovate, unarmed, an inch long, bluntiſh, on petioles the length of the leaves. Racemes branched, axillary, length of the petals. Found in Mexico by Mutis [l].

38. Native of the Society iſles.

39. Native of New Zealand [m].

40. 41. 42. Natives of Jamaica; the firſt of St. Domingo alſo [n].

[a] Desfontaines. [b] Swartz. [c] Hort.-kew. [d] Linn. ſyſt. [e] Swartz prodr. [f] Swartz obſ. [g] Swartz prodr. [h] Linn. ſpec. [i] Swartz prodr. [k] Thunberg. [l] Linn. ſuppl. [m] Forſter. [n] Swartz prodr.

All theſe Nettles from the Weſt Indies are particularly deſcribed by Swartz, in his Flora Indiæ Occidentalis aucta atque illuſtrata: ſcil. n. 7. 9. 10. 11. 12. 16. 17. 21. 22. 24. 25. 27. 28. 29. 30. 31. 32. 33. 34. 40. 41. 42.

43. Stem ſimple, a foot high, rough, with unarmed prickles. Lower leaves oppoſite, the reſt alternate, cordate with the lobes of the baſe approximating, ſerrate, three-nerved, petioled, rough-haired. A branch and a peduncle from each axil. Raceme horizontal, lateral, ſpreading. Male flowers ſolitary from each diviſion, with ſnow-white anthers. Female flowers minute. Seeds drooping in a ring [o].

Native of Surinam, and the Society iſles.

44. 45. Natives of the Society iſles [p].

46. Stem herbaceous, ſimple, grooved, villoſe with awl-ſhaped ſcattered white ſhining briſtles. Leaves alternate, the lower ones entire, the upper trifid, groſsly and bluntly ſerrate, the laſt ſerrature elongated, ſomewhat villoſe, paler underneath, having a few briſtles ſcattered along the nerves, two inches long, on a petiole hiſpid with briſtles, ſhorter than the leaf. Flowers axillary: males above in globular ſpikes; females below. Fruiting rachis branched dichotomouſly, hiſpid [q].

Native of the Eaſt Indies.

47. Stem upright, angular, naked. Leaves acuminate, equally ſerrate, naked twice as long as the petioles, three-nerved. Raceme glomerate, many, diſpoſed in a ſimple ſeſſile ſolitary ſpike. It differs from dioica in having wider alternate leaves. Native of Canada, where it was found by Kalm [r].

48. Native of Virginia and Canada.]

49. Root perennial. Stems two feet high. Flowers in axillary branching aments; appearing towards autumn, but ſeldom followed by ſeeds in this country.

[The plant is at firſt male only, but afterwards male and female flowers are produced on the ſame plant. Native of Canada and Virginia [s]. Cultivated here in 1713 [t].

50. Stem herbaceous, a foot high, flexuoſe, grooved, rough-haired eſpecially at top. Leaves acute, paler underneath, villoſe along the nerves, an inch long on rough-haired petioles, the length of the leaf. Stipules lanceolate-linear. Racemes axillary, ſolitary, ſpreading, compound, longer than the leaf; racemelets ſmall, ſomewhat branched, remotiſh, hairy, ſpreading: flowers glomerate. At firſt view it approaches to the next ſpecies, but differs in its ſhagginеſs, the leaves ſerrate not entire at the baſe, ſharp at the end but not acuminate, and in having branched ſpikes.—It recedes from the preceding ſpecies in having ſmaller leaves ſerrate at the baſe, in its ſhagginеſs, and the racemes being longer than the leaf, not ſuperdecompound [u].

51. Stem herbaceous, annual, two feet high, roundiſh, hiſpid, red, ſometimes creeping. Leaves hiſpid on both ſides. Flowers reddiſh, in long ſpikes; male and female in diſtinct ſpikes: calyx in the males oftener five-leaved than four-leaved: ſtamens alſo commonly five. Native of China and Cochinchina [x].]

52. This is a perennial plant, ſending up many ſtalks from the root, which riſe three or four feet high. Leaves four inches long, and two inches and a half broad, ſerrate, of a deep green on their upper ſide, but very white on their under; having five longitudinal veins; they ſtand upon very long footſtalks. Flowers axillary in looſe aments, and not ſucceeded by ſeeds in England.

[Stem herbaceous, biennial, erect, round, five feet high. Leaves attenuated at the apex, but not at the baſe, with a ſlender point, crenate, above of a duſky green colour, hiſpid, underneath tomentoſe, white. Flowers in many ſmall lateral racemes, male and female in the ſame racemes, the females at the tip. Calyx of the male four-leaved: filaments four, awl ſhaped, flexuoſe, three times as long as the calyx. The females have neither calyx nor corolla; germ roundiſh, ſurrounded with many barren filaments; ſtigmas two, oblong, villoſe [y].

[o] Linn. ſpec. [p] Forſter. [q] Vahl. [r] Linn. ſpec. [s] Reich. ex Fabric. helmſt. [t] Hort. kew. [u] Vahl. [x] Loureiro. [y] Idem.

Native

Native of the Eaſt Indies, China, Cochinchina and Japan. Cultivated in 1739, by Mr. Miller. It flowers here in auguſt and ſeptember.

Thread and cordage even of the thicker kind which might ſerve on board ſhips, are made of Nettles in Japan. Different ſorts grow wild on the hills there, and frequently attain a conſiderable ſize. The ſpecies moſtly uſed are this and the japonica. The bark of theſe, properly prepared, produce ſtrong cordage, and alſo threads ſo fine, that even linnen is made of them. From the ſeeds of the nivea an oil is expreſſed [z].

Loureiro informs us that it is cultivated abundantly in China and Cochinchina, and that it affords an admirable ſtrong thread for ropes of all kinds, and for very durable nets.

Of the bark of one ſpecies of Nettle, they make, at Otaheite, the beſt fiſhing lines in the world, which will hold the ſtrongeſt and moſt active fiſh. They call it Erowa [a].

53. This is a ſmall tree from ſixteen to eighteen feet high, ſimple except at the top where it is ſubdivided, ſcabrous, prickly. Prickles thick, ſhortiſh, ſtanding out, occupying the ſtem longitudinally. Branches herbaceous, prickly, ſtinging very powerfully. Leaves large, a ſpan long, petioled, cordate-ovate, ſerrate, nerved, ſmooth: the nerves underneath and the petioles prickly: the upper ſide of the leaves has convex points terminated by a prickle ſcattered over them. Racemes cauline, many-parted prickly, red. Flowers at the end of the branchlets of the racemes, ſeſſile, dioecious. Calyx of the males one-leafed five-cleft, convex: border ſpreading, little reflexed, with lanceolate, red ſegments: nectary, the bottom of the calyx cup-ſhaped, white. Filaments five, thicker at the baſe, attenuated at the top, twice as long as the ſegments of the calyx, inſerted below the diviſions of it. Anthers three-celled, roundiſh, whitiſh. The rudiment of a piſtil in the middle. Calyx of the female flowers four-lobed, two of the lobes a little bigger. Germ ovate, acute, compreſſed, green. Stigma villoſe, purple. Calyx berried, enlarging, at firſt embracing the germ to the middle but afterwards becoming like a berry, oblong, blunt at the end, four-lobed incloſing the ſeed, white, pellucid. Seed ſmall, black.

Native of the Weſt Indies, on lofty mountains and in ſhady places; flowering in the ſpring [b].

54. Stem erect, round, ſcarcely pubeſcent, harmleſs. Leaves petioled, ſerrate. Spikes lateral, two or three, on a weak rachis, erect. Flowers at remote points, few, heaped. Native of the Cape of Good Hope; found by Thunberg [c].

55. Stem ſuffruticoſe, erect, purple. Branches alternate, from erect ſpreading, reſembling the ſtem. Leaves petioled, rounded-attenuated towards the baſe, entire, having a lanceolate entire cuſp at the end an inch long, ſerrate; above ſcabrous, ſmooth; underneath white-tomentoſe, three-nerved, veiny, unequal, from an inch to a finger's length. Native of Japan [d].

56. This is a little tree or ſhrub, with large leaves, which ſting like our common Nettles, but much more violently, and to ſuch a degree as to cauſe an inflammation in the ſkin. On every vein they have ſharp-pointed tranſparent prickles, containing a fluid, which cauſes this irritation. The Javaneſe are well acquainted with it, and call it Kamadu: the Dutch coloniſts have named it Buffelblad, or Buffalo's leaf. It is cuſtomary with the Javaneſe princes on holidays, by way of diverſion, to turn out a Tiger and a Buffalo to fight, in an area fenced in with planks. If the Buffalo ſhould prove tardy in attacking his adverſary, they flog him with this plant, which cauſes ſuch an heat and inflammation in his ſkin, that he at length becomes quite wild and outrageous. When any one is ſtung with this Nettle-tree, they anoint the part with oil, or with rice boiled to a ſoft conſiſtence; waſhing with water would only render the pain more intolerable. Native of Java [e].

57. Stem four-cornered, grooved, erect, pubeſcent. Leaves cordate-ovate, acuminate, unequally ſerrate, villoſe-ſcabrous, green above, pale beneath, an inch and half long, on petioles ſhorter by half than the leaves. Flowers axillary, glomerate; the glomerules peduncled, round. It differs from the capitata, in having a pubeſcent ſtem, hairy leaves unequally ſerrate, and ſubglobular little balls of flowers. Native of Japan about Nagaſaki; flowering in ſeptember and october. Thick ropes or cables for ſhips are made of the bark of this Nettle [f].

58. Stem round, pubeſcent, hoary at top. Leaves acutely ſerrate, acuminate, ſoftly villoſe, eſpecially the upper ones, quite entire at the baſe and point, an inch and half long, on a ſpreading petiole ſhorter than the leaf. Stipule on each ſide lanceolate acuminate. Balls of flowers axillary, ſeſſile, villoſe, hoary: diſtinguiſhed from the preceding by having the leaves equally ſerrate and even, and the balls of flowers ſeſſile [g].

59. Stem herbaceous, round, ſcarcely a ſpan high. Branches alternate, ſpreading very much. Leaves on very ſhort petioles, obtuſe, ſerrate-crenulate, unequal, ſmall. Globules of flowers ſcattered over the branches, ſmall, ſeſſile. Native of Japan, on the iſland Nipon [h].

Linneus has ſubdivided the numerous ſpecies of this genus into two ſections from the leaves, which from one to thirty-nine incluſive are oppoſite, and in the reſt alternate. We may add, that moſt of the ſpecies are perennial, and ſome of theſe ſhrubby: a few however are annual as n. 1. 2. 3. 8. 17. and 43; perhaps 4. 5. 6. and 9. Linneus has rightly placed this genus in the claſs Monoecia; for although ſome of the ſpecies are Dioecious, as 9. 13. 16. 21. 22. 23. 28. 32. 42, yet it is certain that female flowers are found among the males in ſome, and it is probable that a more minute examination will inform us that the caſe is the ſame in all. Ray, who had juſter notions of the ſexes in plants than moſt other botaniſts of his time, remarks, that Nettles have not only male and female flowers on ſeparate plants, but that they are alſo androgynous, having barren and fertile flowers on the ſame plant, but remote from each other [i].]

PROPAGATION AND CULTURE.

1, 2, 3, &c. Sow the ſeeds in march, upon a bed of rich light earth. When the plants are come up tranſplant them into beds, or the borders of the pleaſure-garden. In july they will flower, and the ſeeds will ripen in autumn. If theſe are permitted to ſhed, they will come up the following ſpring, and flouriſh without farther care.

8. This is a common weed in gardens, and if ſuffered to ſtand, will fill the ground with ſeeds; but as it is an annual, it may be eaſily extirpated by the hoe.

13. The great Stinging Nettle is a formidable root-weed upon the ſides of banks and ditches, in hedges, in uncultivated places in general, and in paſtures; the roots ſpread very much, and it cannot be extirpated without the rooting-iron: pieces of the roots that are left in the ground will grow again.

18. This is eaſily propagated either by ſeeds or parting the roots, and will thrive in moſt ſoils and ſituations.

49. This may be increaſed by parting the roots in the ſpring. It may be planted in almoſt any ſoil or ſituation, and will endure the ſevereſt cold of this climate in the open air.

52. This alſo may be increaſed by parting the roots in may. The plants muſt be ſet in pots filled with light earth. They muſt be houſed in winter, and expoſed to the open air only for three months in the heat of ſummer.

Leafleſs, nectary recurved, ſpike ſimple.

13. Utricularia aurea. *Golden Bladder-wort.*
Lour. cochinch. 26. *ed. Willd.* 32.
Leafleſs, nectary conical-compreſſed, flowers in racemes.

DESCRIPTIONS, *&c.*

1. Roots fibrous, aſh-coloured, with ſmall round tubercles as in the Potato. Scape ſimple, leafleſs, one or two-flowered, ſmooth, erect, half a foot high. Leaves radical, two, obovate, attenuated at the baſe into the petiole, acute, ſhining, thickiſh, veinleſs, convex, oppoſite, an inch and half long. Flowers elegant, very large, white with the calyx and nectary ſlightly tinged with yellow. Native of Martinico, in the higheſt mountains, on a wet open meadow; flowering in february [l].

2. This reſembles our common ſort very much, but the root is creeping. Flowers on the ſcape many, from ſix to ten. It has no bladders at the roots. Native of South America [m].

3. The fibrous floating roots, ſlightly attached to the mud, are ſuppoſed to be perennial. The ſtem likewiſe floats horizontally under water alternately divided

[l] Jacquin. [m] Linn. ſpec.

into

Digitized by Google

into capillary branches, with briſtly leaves bearing little compreſſed curved bladders, open, and bearded at the tip, containing a bubble of air, and a drop of watery fluid, in which, when highly magnified appears a quantity of extremely minute ſolid particles. Aquatic inſects frequently take up their lodging in theſe bladders. The ſtalk riſes erect only a few inches above the water, and is rendered conſpicuous by its ſpike of large handſome alternate flowers (3 to 8): the peduncle and calyx reddiſh or purple; the corolla of one irregular labiate petal, the ſpur conical and recurved, the mouth cloſed, the palate prominent and orange-coloured. Stamens thick and ſhort. Germ ſuperior; ſtyle ſhort; ſtigma concave and bearded [n]. Stem cylindrical, ſcaly towards the top; one ſcale ſerves as a bracte to each flower, and is lanceolate. Calyx permanent; its lower leaf very ſlightly notched at the end. Corolla full yellow, with purpliſh-red ſtreaks. Nectary blunt, lined with minute ſhining globular glands. Filaments thick, fleſhy, crooked, fixed to the baſe of the germ. Stigma two-lipped; one lip very ſmall, the other broad, flat, thin, fringed at the edge: after the impregnation of the germ, this larger lip cloſes the aperture of the ſtyle [o].

Native of Europe, in ditches and ſtagnant waters; flowering after midſummer. It is perfectly an aquatic, and not extremely common in Britain.

4. Roots capillaceous, very tender, floating, loaded with very ſmall membranaceous bladders. Scape length of the finger, ſimple, very ſlender, dividing towards the top into three peduncles, having a bracte under each. Leaves radical, pinnate, capillaceous, with very few equal pinnas. Lower leaflet of the calyx reflexed. Upper lip of the corolla horizontal, cordate, perforated at the baſe, inſerted into the receptacle: lower cordate, bent back at the ſides, at the baſe underneath gibbous, prominent, keeled not horned: throat open, without any prominent palate. Filaments converging, reſembling a ring, narrower below: anthers roundiſh. Germ ovate: ſtyle ſimple, ſhort: ſtigma ovate, tongue-ſhaped [p].

It differs from the preceding in having a ſhort blunt nectary, which projects ſo little, that Linneus calls it carinated, not conical or awl-ſhaped; the palate not ſo prominent as to cloſe the orifice of the corolla; the upper lip blunt; and the corolla of a paler colour. It has alſo fewer flowers, and the plant is only about half the ſize of the other. They agree however in habit and ſtructure [q].

Native of Europe; flowering at the ſame time with the other. On Hounſlow heath, in the river. Hinton, Teverſham, Fulbourn, Sawſton and Chippenham moors, and Gamlingay bogs in Cambridgeſhire. At Cawſton decoy, near Yarmouth, and on St. Faith's bogs near Norwich. Ampthill, and Potton marſhes in Bedfordſhire. Near Glaſtenbury, Somerſetſhire. On turfy bogs in Weſtmoreland and Cumberland. In ditches adjoining Outerthwaite near Flookbury in Cartmell. In a bog at Coryattachan in Skie, and other places in Scotland, but more rarely than the other.

5. Roots capillary, branched, whitiſh. Leaves floating, furniſhed with ſmall ovate bladders. Scape from two to three inches long, filiform, erect, ſimple, ſometimes divided at top, naked, ſmooth. Flowers terminating, alternate, three or four, ſmall, yellow, on long one-flowered peduncles. Tube of the corolla very ſhort, cylindrical: upper lip ovate, convex, entire; lower a little ſmaller, ovate, the orifice cloſed: nectary ſcarcely longer than the lip, conical: palate orange ſtreaked with purple. Filaments inſerted at the aperture of the tube, ſabre-ſhaped; anthers roundiſh, growing to the inner ſide of the filaments, one-celled. Germ roundiſh: ſtyle very ſhort and thick: ſtigma funnel-form, oblique, one-lipped. Capſule roundiſh. Seeds compreſſed, membranaceous at the ſide. It reſembles the preceding ſort very much; but is diſtinct from it, in having a blunt ſubemarginate nectary. Native of Jamaica, in marſhy rivulets; flowering the whole ſummer [r].

6. Leaves capillaceous. Flowers white [s]. Native of Virginia.

[n] Engl. bot. [o] Withering. [p] Linn. ſuec. [q] Linn. ſuec. and Engl. bot. [r] Swartz deſcr. [s] Linn. ſyſt

7. This alſo is a native of Virginia.

8. Stem filiform, a finger's length, bifid or with a double raceme. Flowers alternate, yellow, with the upper lip ſharp at the ſides [t].—Oſbeck adds, that it is very like the vulgaris, but ſomewhat leſs: the calyx-leaf permanent: the nectary conical: the capſule ovate. The plant is a hand's breadth in length; the root fibrous and branched; the bractes very ſmall and ovate; peduncles alternate, compreſſed; flowers ſmall, yellow. Native of China: found by Oſbeck in low ſwampy ground, not under water.

9. Plant ſcarcely an inch high, with a naked root ſomewhat branching. Peduncles nodding, ſupported by a very ſmall ovate ſeſſile bracte. Capſule awl-ſhaped, covered by the permanent calyx. Native of the Eaſt Indies [u].

10. Scape half a foot high, filiform, erect. Flowers few, terminating, ſubſeſſile, with a ſpur the length of the flower. Herman ſays that the colour of the corolla is blue. Native of Ceylon [x], and Malabar.

11. Roots capillary, branched, whorled, floating as in vulgaris, but without bladders. Scape a finger's length, filiform, naked, racemed at the top. In the middle of the ſcape and at the ſurface of the water are from four to ſix ſeſſile ovate ciliate two-celled follicles in whorls, in order to ſupport the ſcape in the water. The corolla has no ſpur; only the lower lip is bagged. Native of the Eaſt Indies, in rice fields, where the water is deepeſt [y]: found by Koenig.—It was alſo found by Forſkahl in Egypt. This differs from the Indian in having oblong bladders at the baſe of the ſcape, inſtead of ovate ones in the middle, but in all other reſpects they are very much alike. There are frequently radical fibres at the top of the bladders of the ſcape [z].

12. Root fibrous, ſhort, without bladders. Stem four inches high, ſlender, quite ſimple, erect. Leaves none. Calyx-leaves large, round-compreſſed. Corolla yellow, with a conical nectary, curved back and almoſt equal to the petal. Capſule lens-ſhaped, protected by the cloſed calyx. In Hon-mo river, near the capital of Cochinchina.

13. Stem ſlender, very long, branched, fluctuating. Root fibrous, capillary, green, branched, having bladders. Scape round, erect, three inches high. Calyx-leaves lanceolate, curved in. Corolla golden-coloured, with a convex emarginate throat, and a conical compreſſed nectary. Native of Cochinchina, in ſlow-flowing rivers [a].

Lin. ſpec. ed. Willd. 2. 1262. *Lamarck encycl.* 1. 590.
Cananga Ouregou. *Aubl. guian.* 1. 608. *t.* 244.

Leaves elliptic acuminate ferruginous beneath, peduncles one-flowered aggregate, petals ovate acute.

8. Uvaria lutea.
Lin. ſpec. ed. Willd. 2. 1262. *Roxb. corom.* 1. 32. *t.* 36.
U. coriacea. *Vahl. ſymb.* 3. 72.

Leaves oblong acute ſhining, peduncles three-flowered ſolitary, petals ovate obtuſe.

9. Uvaria ligularis.
Lin. ſpec. ed. Willd. 2. 1263. *Lamarck encycl.* 1. 590.
Cananga ſylveſtris anguſtifolia. *Rumph. amb.* 2. 198. *t.* 66. *f.* 2.

Leaves ovate acute, peduncles many-flowered ſolitary, petals linear acute very long.

10. Uvaria longifolia.
Lin. ſpec. ed. Willd. 2. 1263. *Vahl. ſymb.* 3. 72. *Lamarck encycl.* 1. 500. *Sonnerat itin.* 2. 233. *t.* 131.

Leaves lanceolate waved at the edge, peduncles umbelled, petals lanceolate acute.

11. Uvaria japonica.
Lin. ſpec. 756. *Reich.* 2. 628. *Willd.* 2. 1263. *Thunb. jap.* 237. *Kæmpf. amoen.* 476. *t.* 477.

Leaves oblong acuminate ſerrate, peduncles one-flowered ſolitary, petals roundiſh.

DESCRIPTIONS, *&c.*

1. This is a climbing ſhrub, by means of a long unarmed branching ſtem, but without tendrils. Leaves alternate, quite entire, ſmooth, on ſhort petioles. Flowers ſcattered, on long peduncles. Calyx ſhort, ſpreading. Corolla duſky red. Anthers ſeſſile, longiſh, compreſſed, placed on a large hemiſpherical receptacle. Germs many, oblong, on the centre of the ſame receptacle. Stigmas as many as the germs, ſcarcely longer than the ſtamens[b]. Berries diſpoſed in a ſimple, rounded, pendulous raceme, formed of the receptacle which is elongated in ripening: they are oblong or cylindric-ovate, knobbed where the ſeeds are, and on the other ſide marked with an indiſtinct groove, peduncled, whitiſh aſh-coloured, (Loureiro ſays black, ſmooth, juicy, acid.) Divided internally into as many horizontal cells as there are ſeeds, and in a double row: partitions membranaceous, very thin. Seeds one in each cell, twelve or fewer, ſemicircular, flat on both ſides, very ſmooth and ſhining, cheſtnut-coloured except the umbilicus, with a white callous margin; faſtened longitudinally to the grooved ſide of the berry[c].

Native of the Eaſt Indies.

Gærtner has two other ſpecies. 1. Uvaria trifoliata, which he refers to Cananga ſylveſtris prima ſ. trifolia of Rumphius, 2. 197. t. 66. f. 1. though he ſays that the ſpecimen he examined did not quite agree with Rumphius's deſcription. It is however clearly a different ſpecies from the zeylanica.—2. U. monilifera; which he thinks may poſſibly be the ſame with Unona diſcreta. Linn. ſuppl. 44 & 270.

Loureiro alſo has a ſpecies which he names Uvaria uncata, becauſe it agrees in habit with Funis uncatus of Rumphius; the flower of that however is different, and it ſeems to belong to Cephalanthus. U. uncata is found about Canton, where it is uſed as a beautiful covering to walls, and is extended and put up without violence.

2. Leaves ſmooth. Flowers in umbels: umbellets ſcattered. Berries ſmall, ſoft, one-celled, containing only one ſeed. Native of Jamaica, and pretty common in the woods of Portland; reckoned one of the beſt timber trees in the iſland, eſpecially where ſtrength or elaſticity is required; but it ſeldom grows to any conſiderable ſize[d]. It is imported under the name of Lance-wood, and is uſed for the ſhafts of very light carriages.

3. Trunk erect, long, and perfectly ſtraight. Branches ſpreading, horizontal: branchlets two-faced. Leaves alternate, two-faced, ſhort-petioled, lanceolate or oblong, entire, about four inches long, and an inch and half broad. Stipules none. Peduncles axillary, ſimple, bowing, bracted near the baſe, round, downy, about an inch long. Filaments very numerous, ſhort, clubbed, grooved, fleſhy, aſcending, placed ſo very cloſe as to preſs upon one another, inſerted into a globular fleſhy receptacle. Anthers four or five-ſided, truncate, a little concave in the centre. Germs about forty, occupying the diſk or centre, oblong, ſeſſile, hairy: ſtyles ſhort: ſtigmas large, purple. Berries many, pedicelled, diverging, in a ſort of umbel, globular, ſize of a ſmall cherry, and very like one when ripe, (dark red,) one-celled. Seed one, round like the berry. Duduga of the Telingas.

It is a large tree, a native of the mountainous inland parts of the Circars. It does not caſt its leaves, and flowers during the hot ſeaſon. The wood is employed for many purpoſes by the natives. The berries are eaten by them when ripe, and are pretty good, but rather too aſtringent.

4. Trunk remarkably ſtraight, with a ſcabrous bark, very deeply ſplit in various directions. Branches horizontal, two faced. Leaves alternate, two-faced, ſhort-petioled, waved, ſmooth on both ſides, of a deep ſhining green, from two to three inches long, and one inch or an inch and half broad. Peduncles oppoſite to a leaf, bowing. Calyx may be ſaid to be ſix-leaved, and corolla three-petalled, as only the three interior of the nine are coloured, coral-like. Stamens as in the preceding. Berries numerous, as in the former, only when ripe black. Seed one, ſhaped as the berry.

This is much more common than the former; ſeldom acquiring the ſize of a tree, except among the mountains. It is in flower and fruit all the year, and does not caſt its leaves. The wood is more uſeful than that of the former; is of a chocolate colour, durable, and very elaſtic.

5. Trunk ſtraight, of conſiderable height and ſize. Branches numerous, horizontal, forming a very large ſhady head. Branchlets two-faced alternate. Leaves alternate, two-faced, ſhort-petioled, oblong or oval, very downy, ſoft, entire, from two to three inches long, by one or two broad. Stipules none. Peduncles ſcattered, generally ſingle, bowing, ſlender, woolly, half the length of the leaf. Calyx and corolla as in U. ſuberoſa. Filaments numerous, very ſhort, not clubbed. Anthers oblong, twin. Germs as in the other, glutinous. Berries ſize of a large nutmeg, round, downy, pulpy, dark purple when ripe. Seeds generally four, nidulant, kidney-form, ſize of a kidney-bean.

It is a large tree, native of the Circar mountains; and flowers during the hot ſeaſon[e].

6. Leaves acuminate, quite entire. Petals flat, acute, and

[b] Loureiro. [c] Gærtner and Loureiro. [d] Browne. [e] Roxburgh.

Digitized by Google

and remarkable for their length. Native of Java and China.

7. Leaves quite entire. Fruit a capſule, (not a berry), one-ſeeded, elliptic, allied to Xylopia, but the capſule is neither four-cornered or two-valved. Native of Guinea, in remote woods [f].

8. Trunk remarkably ſtraight, with the bark dark-coloured and pretty ſmooth. Leaves horizontal, two-faced, ſhort-petioled, oblong or oval, very ſmooth and ſhining, firm, waved, entire, about three inches long and an inch and half broad. Peduncle generally oppoſed to a leaf, very ſhort, from one to ſix-flowered. Flowers dirty, greeniſh, ruſt-coloured, ſhort-pedicelled. Calyx ſmall. Corolla four or five times larger than the calyx. Filaments very ſhort. Anthers oblong, pointed. Germs from four to ſix. Berries the ſame, ſhort-pedicelled, placed in form of a ſtar round their receptacle for a common centre, ſize of a partridge's egg, oval, ſmooth, pulpy, when ripe of a bright yellow. Seeds about ſix, kidney-form, nidulant.

This is alſo a pretty large tree, and grows only among the mountains. Its flowering time is in the hot ſeaſon; and it does not caſt its leaves [g].

9. This approaches to U. odorata in the form of the petals. Native of Amboina [h].

10. Branches ſmooth, with a purple bark, a little flexuoſe at the top. Leaves alternate, a ſpan long, membranaceous, veined, ſmooth on both ſides, gradually attenuated, acute, quite entire. Petiole ſhort, wrinkled beneath. Peduncles lateral, very ſhort, tomentoſe: pedicels ſix or ſeven, ſubumbelled, an inch long, villoſe, a little thicker at top, having a ſmall ovate downy leaflet in the middle. Calyx-leaves ovate, downy, four times ſhorter than the petals. Receptacle the ſize of a Coriander ſeed, downy. Native of the Eaſt Indies [i].

11. Stem fruteſcent, twining and decumbent, tubercled with ſcars, nodding at the top, naked, ruſeſcent. Branches alternate, like the ſtem, almoſt naked, nodding, branchletted. Branchlets ſhort, leafy, like the branches, two inches long. Leaves ſcattered, toothed from the middle to the tip, very finely nerved, thickiſh, ſmooth, paler underneath, two inches long. Petioles ſemicylindric, ruſeſcent, ſhort. Flowers monoecious, ſcattered, peduncled, axillary, drooping. Peduncle filiform, compreſſed, ſmooth, an inch long, curved, having a few ſmall bractes. Corolla ſubglobular, white; petals imbricate, ovate, obtuſe, entire with the margin thinner. Receptacle with the germs ſubglobular, ſtriated, purple, the ſize of a middling pea, incloſed by the calyx and corolla. Filaments two in each aperture between the germs, very ſhort. Anthers ſtanding out, twin, permanent but ſhrivelling, white. Germs numerous, ſmooth, increaſing, red. Berries ſeſſile on the receptacle, ovate, ſmooth, unequal, aggregate, ſucculent, red, one-celled, the ſize of a pea. Seeds two, kidney-form, white [k].

It is diſtinct from all the reſt, in having a twining ſtem, ſerrate leaves, and a large receptacle of the fruit [l].

Native of Japan, and growing very plentifully in ſeveral places round the harbour of Nagaſaki. It is remarkable on account of the great quantity of clear mucus which it contains. When the twigs are deprived of their outer bark, and placed in a glaſs of water, the mucus exſuding, expands itſelf round them for about the thickneſs of a line and upwards, and appears as clear as cryſtal. This mucus is ſometimes uſed for the manufacturing of paper, inſtead of that which they extract from Hibiſcus Manihot; the ladies likewiſe uſe it to render their hair ſmooth and gloſſy [m].

DESCRIPTIONS, &c.

1. Root perennial. Stalk annual, riſing about two feet high, and ſending out one or two branches from the lower part. The flowers come out ſingly from the boſoms of the leaves upon long ſlender footſtalks; they are yellow, hang downwards, and appear at the latter end of april.

[The peduncle has a bent joint in it; and the corolla reſembles that of Medeola aſparagoides [n].

Native of Bohemia, Sileſia, Saxony, Switzerland, Dauphiné, Piedmont.—Cultivated in 1752, by Mr. Miller. It flowers in may [o].

2. Stem round, very hirſute with long denſe hairs,

[n] Linn. ſpec. and ſyſt. [o] Hort. kew.

Digitized by Google

erect, the thickneſs of a quill, a foot high. Leaves alternate, cordate, oblong, acuminate, ſeven-nerved, ſpreading, villoſe with very ſhort hairs, two inches long. Native of Japan near Jedo [p].

3. Native of North America. Introduced in 1785 by Mr. Archibald Menzies. It flowers in july [q].]

4. Root perennial, compoſed of many thick fleſhy fibres, from which ſpring up ſeveral annual ſtalks, which for the moſt part divide into two at a ſmall height from the ground; theſe ſpread aſunder, and have oblong, ſmooth, pointed leaves, broad at their baſe and ſurrounding the ſtem. Petals yellow, oblong, ending in acute points, and ſtanding upon ſlender peduncles, which riſe from the boſom of their leaves, and hang downward. Native of North America.

[Cultivated in 1734, by Peter Collinſon, Eſq [r].

5. This has the habit of the preceding. Stem bifid, one-flowered. Leaves lanceolate-ovate, alternate, but where the flower comes out there are two leaves. Peduncle naked. Native of Canada [s].

6. Stem round, jointed, ſtriated, ſmooth, ſimple, erect. Leaves from the ſame bud two, linear, entire, ſmooth, a finger's length. Flowers from the buds of the leaves, peduncled, drooping. Peduncle reflex, one-flowered, half an inch long. Petals oblong, yellow, about an inch long. Filaments inſerted into the germ, white, half the length of the corolla: anthers oblong, twin, included. Style a little ſhorter than the corolla; but longer than the ſtamens. Stigmas three, reflex. Native of Japan [t].]

PROPAGATION AND CULTURE.

1. 3. 4. 5. Theſe are very hardy plants, and will live in the full ground, but as the flowers have not much beauty, they are only cultivated for the ſake of variety. They are increaſed by parting their roots, the beſt ſeaſon for which is about michaelmas. They may be removed every third year; but if they are removed oftener the plants will not flower ſo ſtrong. They delight in a ſoil not too wet or too ſtiff, but in a gentle hazel loam.

DESCRIPTIONS, &c.

1. Root thick, tuberous, reed-like, of a deep-red colour, ſending out many perpendicular fibres of the ſame colour, and ſpreading into ſeveral offsets. The leaves which riſe immediately from the root are large, with five plaited folds. The biggeſt are two feet long, and three inches broad, of a deep green-colour. The flower ſtalk riſes from the centre of the heads between the leaves to the height of three or four feet, with leaves of the ſame form with thoſe below, but narrower, and ranged alternately, embracing the ſtalk half round with their baſe. The flowers, when young, are incloſed in ſheaths, which, after ſome time, open and make way for the flowers to come out; then they wither and dry, but remain upon the ſtalk like thoſe of the yellow Aſphodel. They form a looſe ſpike, and there are ſeveral upon one common peduncle, which open one after the other. The upper flowers ſtand almoſt upright, but the lower nod; they are hairy and of a ſaffron colour on the outſide, but ſmooth and yellow within. Sometimes the lower petal of the ſix is wanting, but then the place is occupied by the piſtil. [Capſule ſuperior, roundiſh, ſharply three-cornered, three-celled, three-valved: valves bearing the partition in the middle, and ſtriated on the outſide with a few tranſverſe nerves. Seeds in each cell one, flatted a little, obovate or narrowed downwards and ending in a beaked baſe, hirſute all over with ſoft chaffy briſtles, of a brown-black colour; faſtened to the baſe of the cells near the axis [u].

Native of the Cape of Good Hope. Cultivated by Mr. Miller in 1759 [x].

2. Plant when in flower a foot high. Root perennial, a little creeping; furniſhed with oblong cylindrical and nearly perpendicular tubercles. Leaves radical, two-ranked, ſeſſile, equitant, vertical, ſpreading, dilated on the inner ſide at the baſe, channelled, linear-lanceolate, pointed, entire, nerved, bright green, very like thoſe of thyrſiflora, but only one-third of the ſize, dying ſoon after the plant has done flowering, and not appearing again for ſome months. Stalk erect, cylindrical, bearing one or two ſmall leaves, branched, many-flowered. General flower-ſtalks alternate, ſpreading, racemoſe, bearing from three to five flowers, cylindrical, downy: partial ones ſhort, downy, all directed upwards, ſingle-flowered. Bractes ſolitary at the baſe of each of the flower-ſtalks, oblong, pointed, membranaceous, externally downy, ſoon withering, the uppermoſt gradually ſmaller. Petals ſomewhat irregular, obovate, pointed, ſpreading, yellow, externally downy and reddiſh, the three uppermoſt ſtanding neareſt to-

[u] Gærtner. [x] Hort. kew.

gether

Digitized by Google

gether, and marked near the baſe with a purple or greeniſh ſemilunar ſpot, common to them all. Filaments length of the corolla, cylindrical, bent, curved upwards, ſmooth, yellow. Anthers verſatile, reddiſh. Germ ſmall, roundiſh. Style pointing upwards, length of the ſtamens, red towards the top. Stigma marked with a hollow depreſſion, ſmooth, ſmall. Capſule inveſted with the decayed corolla. Seeds roundiſh, rough.

Native of the Cape of Good Hope, where it was gathered in a ſandy ſoil by Mr. Francis Maſſon [y].—Introduced in 1767, by Mr. William Malcolm [z]. This is not the paniculata of Miller, Burman, and Acta nat. cur [a].

3. This ſeems chiefly to differ from the preceding in having hairy leaves, a more ſlender and taller ſtem, reddiſh-brown and not green as in that, its branches more divaricate, the two upper lateral petals more contiguous, and its flowers when cloſed form a ſlenderer and more compact column; the incumbent anthers ſeem alſo to be ſhorter and rounder. Root-leaves oblong lanceolate three or four, about three or four inches high. Stem about three times their length. Segments traverſed longitudinally on the outſide by a brown hairy fillet; outer upper one wholly brown and pubeſcent outwards. Flowers ſcentleſs, opening in ſucceſſion, cloſing towards evening: they expand in the month of july.

Native of the Cape of Good Hope; whence it was introduced by Mr. Williams, nurſery-man at Turnham Green, who received the bulbs about the year 1799 or 1800.

Burman's figure comes nearer to this than to paniculata. The ſynonyms of Breynius and Rudbeck belong to a ſpecies named by Solander, Wachendorfia brevifolia [b].

4. 5. Both theſe are alſo natives of the Cape of Good Hope.]

PROPAGATION AND CULTURE.

Theſe plants may be increaſed by offsets, which are ſent out from the main head, after the ſame manner as ſome of the flag-leaved Iriſes. Take them off at the end of auguſt or the beginning of ſeptember, and plant them in pots filled with ſoft loamy earth mixed with a little ſea ſand; and if the ſeaſon prove hot and dry, place the pots where they may have only the morning ſun, until the offsets have put out new roots; then they may be placed in a ſheltered ſituation, where they may enjoy the full ſun. Here they may remain until there is danger of froſty mornings: then they ſhould be placed in a frame with Ixias, &c. and treated in the manner directed for them.

[The paniculata is impatient of cold, and rarely flowers in England; whereas the thyrſiflora frequently does. The latter always appears covered with luxuriant leaves in the open air; the former even in a greenhouſe loſes its leaves ſoon after flowering, and does not recover them till the end of winter [c].

DESCRIPTION, *&c.*

This is a ſmall tree, about twelve feet high. Leaves alternate petioled oblong acuminate ſerrate ribbed. Corymbs terminating. Flowers ſmall, yellow, inodorous [d]. Fruit berried drupes, diſtant, erect, red, finally brown and ſomewhat wrinkled: pulp thin, drying up with age into a leathery cruſt: ſhell of the ſame form with the drupe, ſomewhat bony, one-celled, valveleſs. Common receptacle ſmall, conical, obtuſe, fungous, emarginate at the edge for the inſertion of the drupes. Proper receptacle, a very ſhort thread from the baſe of the ſhell and inſerted into the middle of the ſeed within ſide. Seed ſoftiſh to the touch [e].

Native of the Eaſt Indies.

WALKERIA. See *Nolana*.]

WALKS are made either of gravel, ſand, or graſs; theſe three ſorts of Walks are the moſt common in England, but where gravel or ſand cannot be procured, they are ſometimes laid with powdered coal, ſea-coal aſhes, and ſometimes powdered brick, but theſe are rarely uſed, when either gravel or ſand can be procured; however, where ſea-coal aſhes can be had, it is preferable to the powdered coal or bricks, becauſe they bind very hard and never ſtick to the feet in froſty weather, which is a good quality; but the darkneſs of its colour has been an objection to the uſe of it in gardens, however for the wilderneſs Walks I think it is preferable to moſt other materials; but I ſhall proceed to give directions for the making of the ſeveral ſorts of Walks, and firſt of the gravel Walks. In order to the laying of Walks in gardens, when they are marked out, the earth ſhould be taken away to a certain depth, that the bottom of them be filled with ſome lime rubbiſh, or coarſe gravel, flint-ſtones, or other rocky materials, which will be ſerviceable to prevent weeds from growing through the gravel, and alſo to keep away worm-caſts. This bottom ſhould be laid ten inches or a foot thick, over which the coat of gravel ſhould be ſix or eight inches, which gravel ſhould be very fine, but yet not ſcreened, becauſe that ſpoils it. This ſhould be laid on a heap, rounding, that the larger rough ſtones may run down on the ſides, which being every now and then raked off, the gravel by that means will be ſufficiently fine. After the gravel has been laid to the thickneſs abovementioned, then the Walks muſt be exactly levelled, and raked true from all great drips, as well as little holes. By this means moſt of the ſtones of the Walks will be raked under your feet, which ſhould rather be gently ſprinkled back again, over the laſt length that is raked, than buried (as is the practice of many gardeners;) by this means the Walk will lie much harder, and the coarſeſt ſtones will very much contribute to its firmneſs.

There is alſo a great fault committed frequently, in laying Walks too round, and ſome to that degree, that they cannot be walked on with that eaſe and pleaſure that ought to be; and beſides, this too great rounding takes off much from the ſeeming breadth and beauty of the Walk.

The common allowance for a gravel Walk of five feet breadth, is an inch riſe in the crown; ſo that if a Walk be twenty feet wide, according to this proportion, it will be four inches higher in the middle than on each ſide; and a Walk of twenty-five feet will be five inches, one of thirty feet ſix inches, and ſo on. When a Walk has been thus carefully laid, trodden down, and raked, or rather, after every length or part of it (which commonly is about fifteen feet each,) then it ſhould be rolled well, both in length and alſo croſs-ways. The perſon who rolls it ſhould wear ſhoes

Digitized by Google

with flat heels that he may not make holes in the Walks, for when theſe are once made in a new Walk, it will not be eaſy to roll them out again.

In order to lay gravel Walks firm, it will be neceſſary to give them three or four water rollings, that is, they muſt be rolled when it rains ſo very faſt, that the Walks ſwim with water; this will cauſe the gravel to bind, ſo that when the Walks come to be dry, they will be as hard as terrace.

Iron-mould gravel is accounted the beſt for binding, or gravel with a little binding loam amongſt it; which latter, though it be apt to ſtick to the heels of ſhoes in wet weather, yet nothing binds better in dry weather.

When the gravel is over-ſandy or ſharp, loam is frequently mixed with it, which, if they be caſt together in heaps, and well mixed, will bind like a rock; whereas looſe gravel is as uncomfortable and uneaſy to walk on, as any other fault in a walk can render it.

The beſt gravel for Walks is ſuch as abounds with ſmooth pebbles (as is that dug at Black-heath,) which, being mixed with a due proportion of loam, will bind like a rock, and is never injured by wet or dry weather, and the pebbles being ſmooth, are not liable to be turned up and looſened by the feet in walking, as are thoſe which are angular and rough; for where Walks are laid with ſuch gravel as is full of irregular ſtones, they appear unſightly in a day's time after rolling, becauſe the ſtones will riſe upon the ſurface whenever they are walked upon, but the ſmooth pebbles will remain handſome two or three days without rolling.

Gravel Walks are not only very neceſſary near the houſe, but there ſhould always be one carried quite round the garden, becauſe being ſoon dry after rain, they are proper for walking on in all ſeaſons; but then theſe ſhould be but few, and thoſe adjoining to the houſe ought to be large and magnificent, proportionable to the grandeur of the houſe and garden. The principal of theſe walks ſhould be elevated and carried parallel with the houſe, ſo as to form a terrace; this ſhould extend itſelf each way, in proportion to the width of the garden, ſo that from this there may be a communication with the ſide Walks, without going on the graſs, that there may be a dry Walk continued quite through the gardens; but there is not a more ridiculous ſight than that of a ſtraight gravel Walk, leading to the front of the houſe, interſecting the graſs, ſo as to make it appear like the ſtiff formal graſs plats frequently made in little court yards by perſons of low taſte.

Graſs Walks in gardens were formerly in great eſteem, and looked upon as neceſſary ornaments to a garden, but of late years they have juſtly been baniſhed by every perſon of true taſte; for thoſe narrow ſlips of graſs were very unſightly, and far from being ornamental, and for the moſt part uſeleſs, being generally too damp for perſons of tender conſtitutions to walk upon; and whenever they were conſtantly uſed, they became bare in the places frequently trodden, ſo were rendered more unſightly; and as the intention of Walks in gardens is to have at all ſeaſons a dry communication throughout the garden, for exerciſe and recreation, graſs Walks were very improper, becauſe every ſhower of rain made them ſo wet, as not to be fit for uſe a conſiderable time, and the dews rendered them too damp for uſe either in the morning or evening; and if the graſs of Walks is not very fine and ſhort like that of the downs, it will be very troubleſome to walk upon; beſides, whenever the ground is ſo dry, as that perſons may with ſafety walk upon graſs, the lawns and other parts of verdure in gardens are better adapted for uſe than any of thoſe formal ſtiff walks which were ſo much eſteemed in the laſt age.

Having given directions for the making of gravel Walks, I ſhall come next to treat of ſand Walks, which are now very frequently made in gardens, as being leſs expenſive in the making, and alſo in keeping, than the former; and in very large irregular gardens, which are ſuch as moſt perſons eſteem, this is a very great article; for as the greateſt part of the Walks which are made in gardens are carried about in an irregular manner, it would be very difficult to keep them handſome, if they were laid with gravel, eſpecially where they are ſhaded by trees; for the dripping of the water from their branches, in hard rains, is apt to waſh the gravel in holes, and render the Walks very unſightly; and when theſe wood Walks are of graſs, they do not appear ſightly, nor are they very proper for walking on; for after rain they continue ſo long damp as to render them unfit for uſe, and the graſs generally grows ſpiry and weak for want of air, and by the continual dropping of the trees, will by degrees be deſtroyed; therefore it is much better to lay theſe Walks with ſand, which will be dry and wholeſome; and whenever they appear moſſy, or any weeds begin to grow on them, if they are ſcuffled over with a Dutch hoe in dry weather, and then raked ſmooth, it will deſtroy the weeds and moſs, and make the Walks appear as freſh and handſome as if they had been new laid.

In the modern way of laying out gardens, the Walks are carried through woods and plantations, ſo that theſe are ſhady and convenient for walking in the middle of the day. Theſe are uſually carried about, winding as much as the ground will admit of, ſo as to leave a ſufficient thickneſs of wood to make the Walks private; and that the perſons who are walking in one part of them may not be ſeen by thoſe who are in any of the other parts. Where theſe Walks are contrived with judgment a ſmall extent of ground will admit of a great many turns, ſo that a perſon may walk ſome miles in a ſmall garden. But theſe turns ſhould be made as natural as poſſible, ſo as not to appear too much like a work of art, which will never pleaſe ſo long as the former.

The breadth of theſe Walks ſhould be proportioned to the ſize of the ground, which in a large extent may be twelve or fourteen feet wide, but in ſmall gardens five or ſix feet will be ſufficient. There are ſome perſons who allow a much greater breadth to their Walks than what I have aſſigned to the largeſt gardens, but as theſe Walks are ſuppoſed to be ſhaded by trees, ſo when they are made too broad, the trees muſt be planted cloſe to the ſides of the Walks; and then it will be a long time before they will afford a ſufficient ſhade, if the trees are young. Therefore I imagine, the width here allowed will by moſt people be thought ſufficient, eſpecially as the walks are deſigned to wind as much as the ground will allow, becauſe the wider they are, the greater muſt be the turns, otherwiſe the Walks will not be private for any ſmall diſtance. Beſides, as it will be proper to line the ſides of theſe Walks with Honeyſuckles, Sweetbriar, Roſes, and many other ſweet flowering ſhrubs, ſo the tall trees ſhould be placed at leaſt five or ſix feet from the Walk, to allow room for theſe. But as I ſhall particularly treat of the method of laying out Wilderneſſes, and planting of them, in ſuch a manner as to render them as nearly reſembling a natural wood as poſſible, under its proper head, I ſhall add nothing more in this place, except a few common directions for making of theſe ſand Walks.

When the ground is traced out in the manner as the Walks are deſigned, the earth ſhould be taken out of the Walks, and laid in the quarters. The depth of this muſt be proportioned to the nature of the ſoil; for where the ground is dry, the Walks need not be elevated much above the quarters, ſo the earth ſhould be taken out four or five inches deep in ſuch places; but where the ground is wet, the bottom of the Walks need not be more than two inches below the ſurface, that the Walks may be raiſed ſo high as to throw off the wet into the quarters, which will render them more dry and healthy to walk on.

After the earth is taken out to the intended depth, the bottom of the walks ſhould be laid with rubbiſh, coarſe gravel, or whatever of the like nature can be moſt readily procured. This ſhould be laid four, five, or ſix inches thick, and beaten down as cloſe as poſſible, to prevent the worms from working through it; then the ſand ſhould be laid upon this about three or four inches thick, and after treading it down as cloſe

as

Digitized by Google

as poſſible, it ſhould be raked over, to level and ſmooth the ſurface. In doing of this, the whole ſhould be laid a little rounded to throw off the wet, but there will be no neceſſity of obſerving any exactneſs therein; for as the whole ground is to have as little appearance of art as poſſible, the rounding of theſe Walks ſhould be as natural, and only ſo contrived, as that the water may have free paſſage from them.

The ſand with which theſe Walks are laid, ſhould be ſuch as will bind, otherwiſe it will be very troubleſome to walk on them in dry weather; for if the ſand be of a looſe nature, it will be moved with ſtrong gales of wind, and in dry weather will ſlide from under the feet. If after theſe Walks are laid, they are well rolled two or three times, it will ſettle them, and cauſe them to be firm. If the ſand is too much inclinable to loam, it will alſo be attended with as ill conſequence as that which is too looſe, for this will ſtick to the feet after every rain; ſo that where ſand can be obtained of a middle nature, it ſhould always be preferred.

In ſome countries where ſand cannot be eaſily procured, theſe Walks may be laid with ſea ſhells well pounded, ſo as to reduce them to a powder, which will bind extremely well, provided they are rolled now and then; but where neither of theſe can be eaſily procured, ſea-coal aſhes, or whatever elſe can be gotten, which will bind, and will be dry to the feet, may be uſed for this purpoſe; and where any of theſe can only be had in ſmall quantities, the Walks ſhould have a greater ſhare of rubbiſh laid in their bottom, and theſe ſpread thinly over them; and in moſt places rubbiſh, rough ſtones, or coarſe gravel, may be eaſily procured.

WALLS are abſolutely neceſſary in gardens, for the ripening of all ſuch fruits as are too delicate to be perfected in this country without ſuch aſſiſtance. Theſe are built with different materials; in ſome countries they are built of ſtone, in others with brick, according as the materials can be procured beſt and cheapeſt.

Of all materials proper for building Walls for fruit-trees, brick is the beſt; in that it is not only the handſomeſt, but the warmeſt and kindeſt for the ripening of fruit; beſides that, it affords the beſt conveniency of nailing, for ſmaller nails will ſerve in them than in ſtone Walls, where the joints are larger; and brick Walls, with copings of free-ſtone, and ſtone pilaſters or columns, at proper diſtances, to ſeparate the trees and break off the force of the winds, make not only the moſt beautiful, but the moſt profitable Walls.

In ſome parts of England there are Walls built both of brick and ſtone, which are very commodious. The bricks of ſome places are not of themſelves ſubſtantial enough for Walls, nor are they any where ſo durable as ſtone; and therefore ſome perſons, that they might have Walls both ſubſtantial and handſome, have built double ones, the outſide being of ſtone, and the inſide of brick, or a ſtone Wall lined with brick; but when theſe are built, there muſt be great care taken to bind the bricks well into the ſtone, otherwiſe they are very apt to ſeparate one from the other, eſpecially when froſt comes after much wet, which ſwells the mortar, and frequently throws down the bricks when the Walls are only faced with them, and not well tied into the ſtone.

Where the Walls are built entirely of ſtone, there ſhould be trelliſſes fixed up againſt them, for the more convenient faſtening the branches of the trees: the timbers of theſe eſpaliers need not be more than an inch and a half thick, and about two inches and a half broad; theſe ſhould be fixed croſs each other, at about four inches diſtance; for if they are at a much greater diſtance, it will be difficult to faſten the ſhoots of the trees properly. As this trellis will be laid cloſe to the Wall, the branches of the trees will lie about two inches from the Wall, in which poſition the fruit will ripen better than when it lies quite cloſe to the Wall; ſo that where ſtone Walls are built, there ſhould always be theſe eſpaliers framed againſt them, which will render theſe Walls very good for fruit trees, which, without the eſpaliers, ſeldom are found to anſwer the purpoſe of ripening the fruits well, beſides the inconvenience of having no good faſtening for the branches of the trees.

There have been ſeveral trials made of Walls built in different forms; ſome of them having been built ſemicircular, others in angles of various forms, and projecting more towards the north, to ſcreen off the cold winds; but there has not been any method as yet which has ſucceeded near ſo well, as that of making the Walls ſtraight, and building them upright.

The faireſt trial which I have ſeen made of circular Walls, was at Goodwood in Suſſex, the ſeat of the Duke of Richmond, where, in the middle of two ſouth Walls, there were two large ſegments of circles, in which were the ſame ſorts of fruit-trees planted, as againſt the ſtraight parts of the Walls; but there never was any fruit upon the trees in the circular part of the Walls, which came to maturity; nor were the trees of long continuance, being blighted every ſpring, and in a few years were totally deſtroyed; and when the branches of thoſe trees which grew upon the ſtraight parts of the Walls, had extended themſelves ſo far, as to admit of their being led into the circular parts of the Walls, they were conſtantly blighted and killed.

When the trees which had been planted in the circular parts were deſtroyed, the Walls were filled with Vines; but the Grapes of the ſame ſort were a full month later than thoſe growing againſt the ſtraight parts of the Walls, ſo that they rarely ripened, which occaſioned their being rooted out, and Figs were afterwards planted, but the fruit of theſe ſucceeded little better; nor can it be ſuppoſed that any trees or plants will thrive ſo well in theſe circles, where there is a conſtant draught of air round them, which renders the ſituation much colder than the open free air.

I have alſo ſeen at Mr. Le Cour's garden in Holland, ſome Walls built in angles of different forms, but theſe ſucceeded no better than the circles before-mentioned; for I did not find one tree in health againſt the Walls, nor did they produce fruit.

There are ſeveral other ſchemes which have been propoſed by different perſons, for the building of Walls to accelerate the ripening of fruits, among which there was a very ingenious book written ſome years ago, intitled, Fruit Walls improved, by inclining them to the horizon; in which the author has ſhewn by calculation that there will be a much greater number of the rays of the ſun fall upon ſuch Walls, than upon thoſe which are built perpendicular; and from thence he has drawn calculations, that Walls ſo built will be of great ſervice in the accelerating of fruit; and he has taken the trouble of calculating the different inclinations which ſuch Walls ſhould have in the different climates, in order to receive the greateſt number of the ſun's rays. This theory ſeems to have all the demonſtration neceſſary for its ſupport, but upon trial they have not ſucceeded in the leaſt; for as theſe Walls muſt be built againſt banks of earth, the damps which ariſe from the ground overbalance the advantage of the ſun's rays; beſides, theſe ſloping Walls being more expoſed to the cold dews in the night, the fruit will be much more chilled thereby; and in the ſpring the morning froſts will prove much more deſtructive to the tender bloſſoms of the fruit-trees, as they will be more expoſed to them, than againſt an upright Wall; add to this, their being much more expoſed to the winds and the rain; and it will be found, by comparing the advantages propoſed from theſe Walls, with the diſadvantages to which the fruit-trees will be expoſed, that upright Walls will have the preference; for it is not the ſtrongeſt rays of the ſun in the heat of ſummer, which are ſo much wanting for ripening of fruit, as the continuance of a moderate ſhare of warmth; and above all, the having of the ſun in a morning, to dry off the cold dews of the night early, is of the greateſt uſe; and in this reſpect the upright Walls are much preferable to the ſloping, as they will have the direct rays of the ſun in the morning, which will be oblique on the other, and renders thoſe Walls which are built inclining to the eaſt preferable to

Digitized by Google

ſouth Wales, as the fruit will always ripen earlier againſt them.

There are ſome perſons who recommend the painting of Walls black, or of a dark colour, as they ſuppoſe the dark colour will imbibe more of the ſun's rays, ſo will retain the warmth longer; this alſo anſwers better in theory than in practice; for although it muſt be allowed that a black Wall is warmer to the touch than a common brick Wall, yet, as the fruit generally is ſituated at a ſmall diſtance from the Wall, it receives no benefit from the warmth of the Wall, and it is the reflected heat which accelerates the ripening of fruit; therefore I would adviſe every one to make fair trials of theſe things, before they put them in practice, and not to take upon truſt what they may be told by perſons who are too ſanguine in recommending to others ſchemes which they have adopted upon very ſlight principles, or perhaps upon a ſingle trial; this painting of the Walls is recommended by the ſame perſon who wrote upon inclining Walls, and he has propoſed this upon the ſame principles; but the introducing of theſe ſchemes ſhould be avoided, until there have been ſufficient trials made to warrant their uſe.

Where perſons are willing to be at the expence, in the building of their Walls ſubſtantial, they will find it anſwer much better than thoſe which are ſlightly built, not only in their duration, but alſo in their warmth; therefore a wall two bricks thick, will be found to anſwer better than one brick and a half; and if in the building of garden walls they are grouted with ſoft mortar, to fill and cloſe all the joints, the Walls will be much ſtronger, and the air will not ſo eaſily penetrate through them, as it does through thoſe which are built in the common way.

According to the modern taſte in gardening, there are very few Walls built round gardens, which is certainly very right, not only with regard to the pleaſure of viewing the neighbouring country from the garden, but alſo in regard to the expence, 1. Of building theſe Walls; 2. If they are planted with fruit, as is frequently practiſed, to maintain them will be a conſtant charge, without receiving much profit or pleaſure; for when there is too much Walling planted with fruit-trees, they are ſeldom taken much care of; ſo that the quantity of fruit produced will be ſmall, and that ill-nouriſhed and bad taſted, therefore the quantity of Walling ſhould be proportioned to the fruit conſumed in the family; but as it will be neceſſary to incloſe the kitchen-garden for the ſecurity of the garden ſtuff, ſo if that be walled round, it will contain as much fruit as will uſually be wanted in the family; becauſe the kitchen-garden is always proportioned to the number of perſons maintained; but if the quantity of Walling which ſurrounds the kitchen-garden ſhould be judged too little for the ſupply of fruit, there may be a croſs Wall built through the middle of the kitchen garden; or, where the ſize of the garden will admit, there may be two croſs Walls built; but this muſt not be done where there is not room to place the Walls at leaſt eighty or one hundred feet aſunder; and if they are allowed a much greater diſtance it will be better; and as the kitchen-garden ſhould always be placed out of ſight from the houſe, the Walls may be hid by plantations of trees, at ſome little diſtance, which will be of uſe in ſheltering the fruit.

The beſt aſpect for Walls in England is, to have one point to the eaſtward of the ſouth, for theſe will enjoy the benefit of the morning ſun, and will be leſs expoſed to the weſt and ſouth-weſt winds (which are very injurious to fruits in England) than thoſe Walls which are built due ſouth. I know there are many perſons who object to the turning of Walls the leaſt point to the eaſt, on account of the blights which they ſay come from that quarter in the ſpring; but from many years experience and obſervation I can affirm that blights as often attack thoſe Walls which are open to the ſouth-weſt, as thoſe which are built to any other aſpect; and I believe, whoever will be at the trouble to obſerve for ſeven years, which aſpected Walls ſuffer moſt rom blights, will find thoſe which are built with a point to the eaſtward of the ſouth, as ſeldom blighted, as thoſe which are turned to any other aſpect; therefore, in the contrivance of a kitchen-garden, there ſhould be as great length of theſe Walls built, as the ſituation of the ground will admit.

The next beſt aſpect is due ſouth, and the next to that ſouth-eaſt, which is preferable to the ſouth-weſt, for the reaſons before aſſigned; but as there will, for the moſt part, be ſouth-weſt, and weſt Walls in every garden, theſe may be planted with ſome ſorts of fruit, which do not require ſo much heat to ripen them, as thoſe deſigned for the beſt Walls; but wherever there are north Walls, thoſe will only be proper for baking Pears, Plumbs and Morello Cherries for preſerving, or ſome Duke Cherries may be planted againſt theſe Walls, to continue them longer in the ſeaſon, which will be found uſeful in ſupplying the table till Peaches, Nectarines, and Plums, are ripe.

Where perſons are very curious to have good fruit, they erect a trellis againſt their Walls, which projects about two inches from them, to which they faſten their trees; which is an excellent method, becauſe the fruit will be at a proper diſtance from the Walls ſo as not to be injured by them, and will have all the advantage of their heat; and by this method the Walls will not be injured by driving nails into their joints, which by every year being drawn out, draws out the mortar from between the bricks, and thereby makes holes, in which ſnails and other vermin will harbour and deſtroy the fruit, and the Walls will be alſo greatly impaired.

Theſe trelliſſes may be contrived according to the ſorts of fruit which are planted againſt them. Thoſe which are deſigned for Peaches, Nectarines, and Apricots (which, of the moſt part, produce their fruit on the young wood) ſhould have their rails three, or at moſt four inches aſunder every way; but for the other ſorts of fruit, which continue bearing on the old wood, they may be five or ſix inches apart, and thoſe for Vines may be eight or nine inches diſtance. For as the ſhoots of Vines are always trained at a much greater diſtance than thoſe of any other ſort of fruit, the trelliſſes for theſe need not be near ſo cloſe, eſpecially as thoſe muſt for Peaches and Nectarines, whoſe ſhoots are generally ſhortened to about five or ſix inches or leſs; ſo that if the rails are not pretty cloſe, many of the ſhort branches cannot be faſtened to them.

Theſe trelliſſes may be made of any ſort of timber, according to the expence which the owner is willing to beſtow; but Fir is moſt commonly uſed for this purpoſe, which if made of yellow deal, well dried and painted, will laſt many years; but if any perſon will go to the expence of Oak, it will laſt ſound much longer, eſpecially if the trees are fallen in winter. And if any one is unwilling to be at the expence of either, then a trellis may be made of Aſh poles, in the ſame manner as is practiſed in making eſpaliers for counter borders, with this difference only, that every fourth upright rail or poſt ſhould be very ſtrong, and faſtened with iron hooks to the Wall, which will ſupport the whole; and as theſe rails muſt be laid much cloſer together, than is generally practiſed for eſpaliers, theſe ſtrong upright rails or poſts ſhould not be farther diſtant than three, or at moſt four feet from each other. To theſe the croſs rails which are laid horizontally ſhould be well nailed, which will ſecure them from being diſplaced, and alſo ſtrengthen the trellis, but the other ſmaller upright poles need only be faſtened with wire. To theſe trelliſſes the ſhoots of the trees ſhould be faſtened with oſier twigs, rope-yarn, or any other ſoft bandage, for they muſt not be nailed to it, becauſe that will decay the wood-work.

Theſe trelliſſes need not be erected until the trees are well ſpread, and begin to bear fruit plentifully; before which time the young trees may be trained up againſt any ordinary low eſpaliers, made only of a few ſlender Aſh poles, or any other ſlender ſticks; by which contrivance the trelliſſes will be new when the trees come to bearing, and will laſt many years after the trees have overſpread them; whereas, when they are made before the trees are planted, they will be half decayed before the trees attain half their growth.

Where

Digitized by Google

Where theſe trelliſſes are intended to be made againſt new Walls, it will be proper to faſten ſome ſtrong iron hooks into the Wall as it is built, at the diſtance which the upright poſts are intended to be placed; becauſe when theſe are afterwards driven into the Wall, they diſplace the mortar in the joints, and injure the Wall. In the building of the Walls round a kitchen-garden, the inſides which are deſigned to be planted with fruit-trees ſhould be made as plain as poſſible, ſo that the piers ſhould not project on thoſe ſides above four inches at moſt; and theſe ſhould be placed about fourteen feet aſunder, in ſuch Walls as are deſigned for Peach and Nectarine-trees; ſo that each tree may be planted exactly in the middle between the piers, which will render them more ſightly, and be better for the trees; but where Apricots, Plumbs, or Cherries are to be planted, the piers may be only ten feet aſunder; and againſt every other pier the trees ſhould be planted, which will allow them ſufficient room to ſpread; as the trellis will project as forward as the piers, the branches of the trees may be trained on a plain; but when the piers project no more on the inſide of the garden, they ſhould be built ſtronger on the outſide, for the better ſupporting of the Walls.

The uſual thickneſs which garden Walls are allowed, if built with bricks, is thirteen inches, which is one brick and a half, but this ſhould be proportionable to the height; for if they are built twelve or fourteen feet high or more, as is often practiſed, then the foundations of the Walls ſhould be at leaſt two bricks and a half thick, and brought up a foot or more above the level of the ſurface of the ground, of the ſame thickneſs; then they ſhould be ſet off two inches on each ſide, which will reduce them to two bricks; and five or ſix feet above the ſurface of the ground, they may be diminiſhed on each ſide, to reduce them to the thickneſs of a brick and a half; which muſt be continued to the top of the Walls, and the piers in theſe high Walls ſhould alſo be proportionably ſtronger than is commonly allowed to lower Walls; for as theſe will be much more expoſed to ſtrong gales of wind, if they are not well built, they will be in danger of being blown down; therefore the piers of theſe Walls ſhould be projected the length of a brick on their backſide, and the thickneſs of a brick on their front; and if theſe are built about ten or twelve feet aſunder, they will greatly ſtrengthen the Walls.

But there is no neceſſity for building Walls higher than nine or ten feet, unleſs it be for Pears, which, if properly managed, will ſpread over a great compaſs of walling; but as only ſome of the lateſt winter Pears require the aſſiſtance of a Wall, there need no more but that part of the Wall where theſe are deſigned to be built higher; for Peaches and Nectarines never require a Wall higher than nine or ten feet, provided they are rightly managed; becauſe whenever they are carried to a greater height, the lower part of the Wall is unfurniſhed with bearing branches; and although Apricots, Plums, and Cherries will frequently grow higher, yet if they are planted at a proper diſtance, and the branches trained horizontally from the bottom, they will not ſoon cover a Wall of this height; and Vines may be kept as low as any ſort of fruit, for when they are planted againſt low Walls, they muſt be treated ſomewhat after the ſame manner as thoſe in vineyards, which is, to cut out the greateſt part of the wood which produced fruit the preceding year, and train in new ſhoots for the next year's bearing, which are rarely left a yard in length, therefore will not require very high Walls.

If the Pears which are deſigned to be planted, are allowed a ſouth-weſt aſpect, on which they will ripen very well, then the Wall to this aſpect ſhould be built fourteen feet high or more; for as theſe trees ſpread very far when on free ſtocks, they ſhould not be ſhortened and ſtopped in their growth, which will prevent their bearing, by cauſing them to ſend out a great number of groſs luxuriant ſhoots, which will never produce fruit; therefore theſe ſhould never be planted amongſt other ſorts of fruit-trees which are of leſs growth, becauſe then the Walls muſt appear very unſightly in having ſome trees planted more than double the diſtance which the others require; ſo that there is no other ſort of fruit which requires the aſſiſtance of Walls to ripen their fruit, which need ſo great room for ſpreading as Pears, except it be Figs, a few trees of which may be planted againſt the ſame Walls where there is room; though theſe may be planted againſt the back Walls of offices or ſtables, where there is conveniency, becauſe this fruit is ſeldom coveted by ſervants; and being planted in places which are much frequented, they will not be in ſo much danger of being deſtroyed by birds, as thoſe which are in private places. But I ſhall now proceed to give ſome directions for the building of hot Walls, to accelerate the ripening of fruits, which is now pretty much practiſed in England.

In ſome places theſe Walls are built at a very great expence, and ſo contrived as to conſume a great quantity of fuel; but where they are judiciouſly built, the firſt expence will not be near ſo great, nor will the charge of fuel be very conſiderable, becauſe there will be no neceſſity of making fires more than three or four months, beginning about the middle or latter end of january, and ending by the end of may, when there will be no want of fires, if the glaſſes are cloſe ſhut every night, or in bad weather; for half an hour's ſun-ſhine on the glaſſes at that ſeaſon will ſufficiently warm the air incloſed in the glaſſes, for the growth of any of our European fruits.

There are ſome perſons who plant Vines, and other fruit-trees by the ſides of ſtoves, and draw ſome of their branches into the ſtove, in order to obtain early fruit; but this is by no means right, where the ſtove is deſigned for Ananas, becauſe the air muſt be kept much warmer for them than is required for any of the other fruits, ſo that they can never ſucceed well together; for when there is only a ſufficient quantity of air admitted for the growth of the other fruit, the Ananas are ſtarved for want of proper heat; and ſo on the contrary, when the ſtove is kept up to the proper heat for the Ananas, it will be too hot for other fruits; and it will alſo be proper to have the Vines on a particular Wall by themſelves, becauſe theſe require to have a greater ſhare of air admitted to them when they begin to ſhoot, than ſome other ſorts of fruit, ſo that it is by much the better method to have them ſeparate.

The ordinary height of thoſe hot Walls is about ten feet, which will be ſufficient for any of thoſe ſorts of fruits which are generally forced; for by forcing of the trees, they are commonly weakened in their growth, ſo that they will not grow ſo vigorouſly as thoſe which are always expoſed to the open air; and where there is not a quantity of Walling planted ſufficient to let one part reſt every other year, the trees will never be very healthy, and will laſt but a few years. The quantity of Walling to produce early fruit for a middling family cannot be leſs than eighty or one hundred feet in length; therefore where a perſon is deſirous to have the fruit in perfection, and the trees to continue in a good condition many years, there ſhould be three times this quantity of Walling built; ſo that by dividing it into three parts, there will be two years for the trees to recover their vigour between the times of their being forced, whereby a greater quantity of bearing wood may be obtained, and the fruit will be fairer, and in larger quantities, than when they are forced every year, or every other year; and as the glaſſes may be contrived ſo as to move from one to the other, the expence of building the Walls ſo much longer, will not be very great, becauſe the frames and glaſſes will be the ſame as for one year's fruit.

The foundations of theſe Walls ſhould be made four bricks and a half thick, in order to ſupport the flues; otherwiſe, if part of them reſt on brick-work, and the other part on the ground, they will ſettle unequally, and ſoon be out of order; for wherever there happen any cracks in the flues, through which the ſmoke can make its eſcape, it will prevent their drawing; and if the ſmoke gets within the glaſſes, it will greatly injure the fruit, and give it a ſmoky taſte. This thickneſs of Wall need not be continued more

Digitized by Google

than ſix inches above the ground, where ſhould be the foundation or bottom of the firſt flue, which will be ſufficient to raiſe it above the damps of the earth; then the Walls may be ſet off four inches on each ſide, which will reduce it to the thickneſs of three bricks and a half, ſo that the back Wall may be two bricks thick, which is abſolutely neceſſary to throw the heat out more in front; for when the back Walls are built too thin, the heat will eſcape through them. The Wall in front next to the fruit, ſhould be only four inches thick, whereby there will be allowance of nine inches for the flues, which may be covered with twelve inch tiles; for if they have an inch and a half bearing on each ſide, it will be ſufficient. The ovens in which the fires are made, muſt be contrived on the backſide of the Walls, which ſhould be in number proportionable to the length of the Walls. The length uſually allowed for each fire to warm is forty feet, though they will do very well for fifty feet; but I would not adviſe the flues to be longer than this to each fire, becauſe when the ovens are made at a great diſtance, there is a neceſſity of making the fires ſo much ſtronger to warm the Walls, which will occaſion the heat to be too violent near the fires. Theſe ovens ſhould be ſhedded over to keep out the wind and rain, otherwiſe the fires will not burn equally. Some people make theſe ſheds of timber, but it is much better to build them of brick, and tile them over, becauſe the wooden ſheds will in a few years decay, and afterwards be a conſtant charge to keep them in repair; and beſides they may be in danger of firing, if great care is not conſtantly taken of the fires. As it is abſolutely neceſſary to have the ovens below the foundation of the firſt flues, there muſt be ſteps down into the ſheds, to come to the mouth of the ovens to ſupply the fuel, therefore the ſheds ſhould not be narrower than eight feet in the clear; for as the ſteps will require four feet ſpace, there ſhould be at leaſt four feet more for the perſon who attends the fire, to have room to turn himſelf to clear out the aſhes, and to put in the fuel. Where the length of Walling requires two ovens, it will be proper to have them in the middle included in one ſhed, which will ſave expence, and allow more room to attend the fires; for in this caſe the ſheds muſt be at leaſt ten feet long, and they need not be more than ſix in breadth. The ſteps down into theſe ſhould be at one end, ſo that the door opening into the ſheds will not be oppoſite to the mouths of the ovens, therefore the fires will burn more regular; for whenever the doors are contrived to front the mouth of the ovens, if the wind ſets directly againſt them, it will cauſe the fire to burn too fiercely, and the fuel will be ſoon conſumed.

Theſe ovens may be contrived in the ſame manner as thoſe which are already deſcribed for ſtoves, wherefore I ſhall not repeat it again in this place; but muſt obſerve, that when the two ovens are joined together, there ſhould be a partition Wall at leaſt three bricks thick between them, otherwiſe the fires will ſoon deſtroy it; and if there ſhould be the leaſt hole in the Wall, through which the ſmoke of the two fires can communicate, it will prevent their drawing.

The lower flue through which the ſmoke firſt paſſes from the fire, may be two feet and a half deep: therefore the back Wall ſhould be at leaſt two bricks and a half thick, as high as to the top of this flue; and then it may be ſet off to two bricks, which muſt be continued to the top of the Wall. The ſecond flue, which ſhould return over the firſt, may be made two feet, the third a foot and a half, and the fourth one foot deep; which four flues, with their coverings, will riſe near eight feet in height; ſo that there will be about two feet left for fixing of the frames at the top to ſupport the glaſſes, and for the coping of the Wall. And theſe four returns will be ſufficient to warm the air in the frames, for the ſmoke will have loſt its heat by the time it has paſſed thus far.

In the carrying up of theſe Walls, there ſhould be ſome ſtrong iron hooks faſtened at convenient diſtances which ſhould project about two inches from the Wall, to which the trellis muſt be faſtened which is to ſupport the trees. Theſe hooks ſhould be long enough to faſten into the back Wall, for the Wall in front being but four inches thick, will not be ſtrong enough to ſupport the trellis; but in placing of them care ſhould be taken not to lay them croſs the middle of the flues, becauſe they would obſtruct the clearing the flues of ſoot whenever there ſhould be occaſion; ſo that the beſt way is to lay them juſt under the tiles which cover each flue, at about three or four feet aſunder, which will be near enough, provided the hooks are made ſufficiently ſtrong. As the flues muſt be well pargetered with loam on their inſide, ſo likewiſe ſhould the loam be ſpread under the tiles which cover them, to the thickneſs of the hooks, that the flues may be very ſmooth, otherwiſe the ſoot will hang to the iron hooks and ſtop the ſmoke from paſſing. It will be very proper to cover theſe flues on the ſide next the trellis with hop-bags, or ſome ſuch coarſe cloth, in the manner as hath been directed for the ſtoves, which will make them ſo tight that no ſmoke will find its way into the frame, which, without this covering, it is very apt to do through the joints of Walls, eſpecially when they are ſo thin as theſe muſt be built; and this covering will alſo ſtrengthen the Wall of the flues, and join the whole work together. If at each end of theſe flues there are ſmall arches turned in the back Walls, in ſuch a manner that there may be holes opened to clean the flues of ſoot whenever there is a neceſſity for it, the trouble will be much leſs than to open the flues in front, by which there will be no damage done to the trees, nor will the flues be in the leaſt injured by this, which they muſt be, when they are opened in front.

The borders in front of theſe hot Walls ſhould be about four feet wide, which will make a ſufficient declivity for the ſloping glaſſes; and in theſe borders there may be a row of Dwarf Peas planted to come early, or a row of dwarf Kidney-beans, either of which will ſucceed very well; and if they are not planted too near the trees, will not do them much injury. On the outſide of theſe borders ſhould be low Walls erected, which ſhould riſe four or ſix inches above the level of the borders, upon which the plate of timber ſhould be laid, on which the ſloping glaſſes are to reſt; and this Wall will keep up the earth of the border, and alſo preſerve the wood from rotting.

The glaſſes which are deſigned to cover theſe Walls, muſt be divided into two ranges, for as they muſt reach from the ground-plate (juſt above the level of the border) to almoſt the top of the Wall, they will be more than twelve feet long, which will be too great a length for ſingle frames, which when they are much more than ſix feet long, are too heavy to move, eſpecially if the frames are made of a proper ſtrength to ſuſtain the glaſs. Theſe frames ſhould be contrived in ſuch a manner, as that the upper row may ſlide down; and by making on one ſide three ſmall holes in the wood-work which ſupports the frames, at about a foot diſtance, and having a ſmall iron pin to fix into them, the top glaſſes may be let down one, two, or three feet, according as there may be occaſion to admit air. The lower row of glaſſes may be contrived ſo as to take eaſily out; but as they muſt lie ſloping, and the upper row muſt bear on them, they cannot be contrived to ſlide upwards; nor indeed will there be any occaſion for their moving, becauſe it is much better to let the air in at the top, than in the front of the trees.

The ſloping timbers which are to ſupport the glaſs frames muſt be faſtened at bottom into the ground-plate in the front of the border, and at the top into ſtrong iron cramps fixed in the upper part of the Wall for that purpoſe. Theſe timbers ſhould be made of Fir, which will not twiſt, as Oak and ſome other wood will, where it is laid in ſuch poſition. They muſt be made ſubſtantial, otherwiſe they will not laſt many years, eſpecially as they are deſigned to be moveable. On the top of theſe ſhould be fixed a ſtrong board, under which the upper row of glaſſes ſhould ſlide. The uſe of this board is to ſecure the upper part of the glaſſes from being raiſed by the winds, and alſo to keep the wet from getting to the trees; therefore

Digitized by Google

therefore it ſhould be joined as cloſe as poſſible to the Wall, and ſhould project about two inches over the glaſs frames, which will be enough to throw the wet on the glaſſes, and likewiſe to ſecure them faſt down.

The breadth of theſe frames for the glaſſes may be about three feet or a little more, according as the diviſions of the length of the Wall will admit; for a ſmall matter in their width is of no conſequence, provided they are not too wide to be eaſily moved; for when they are wider than a man can eaſily reach his arms to manage, they will be very troubleſome to carry from one place to another. The bars of theſe frames, which are to ſupport the glaſs, ſhould be placed lengthwiſe of the frames; for when they are placed acroſs, they ſtop the moiſture which is lodged on the inſide of the glaſſes, and cauſe it to fall in drops on the borders at every bar, which will be very injurious to any plants which are put there; and if it fall on the trees will greatly damage them, eſpecially when they are in bloſſom. The lead into which the glaſſes of theſe frames are fixed, ſhould be very broad, and the joints well cemented, otherwiſe the wet will find an eaſy paſſage through, and do great damage to the fruit.

At each end of the range of glaſſes, there will be an angular ſpace between the glaſſes and the Wall, which muſt be cloſely ſtopped to prevent the air from getting in, which might greatly injure the fruit. Theſe are by ſome perſons cloſely boarded up; but if they are cloſed with glaſſes, ſo contrived as to open to let in air at proper times, it will be of great advantage; becauſe when the wind may be ſtrong againſt the front-glaſſes, one or both of theſe end-glaſſes may be opened, according to the warmth of the air incloſed, which will be often very uſeful to cool the air, and to admit a ſmall quantity of freſh air to the fruit.

The ſorts of fruit which are uſually planted for forcing, are Cherries, Plums, Peaches, Apricots, and Nectarines, but the laſt-mentioned rarely ſucceed well, nor will the trees continue long, ſo that they are ſcarce worth planting againſt hot Walls. As for the Vines, I would propoſe they ſhould be planted by themſelves againſt a particular Wall; for as they will require more air to be admitted to them when they begin to ſhoot, than any of the above-mentioned fruits, they will not all ſucceed if they are included in the ſame frame. As to the others, they will do very well in the ſame border, and will demand the ſame temperature of warmth. The beſt of theſe ſorts to plant againſt theſe hot Walls, are thoſe here mentioned:

Cherries.

The Early May, and May Duke.

Plums.

The Mirabelle.
The Early Black Damaſk, or Morocco.
The Great Damaſk Violet of Tours.
The Drap d'Or.

Peaches.

The Red Nutmeg.
The Red Magdelain.
The Montauban.
Early Newington.
Violet Hative.

Nectarines.

Fairchild's Early Nutmeg.
The Elruge.

Apricot.

The Maſculine.

Theſe being the ſorts which ripen early, are the moſt proper to plant againſt theſe Walls, although they are not ſo valuable as ſome other ſorts of theſe fruits; yet, as they naturally ripen three weeks or a month earlier in the ſeaſon, they will be very early ripe, when they are brought forward by artificial warmth.

In the preparing of the borders for planting theſe fruit-trees, there ſhould be the ſame care taken as for thoſe againſt open borders, which, being fully treated of in another part of this work, I ſhall not repeat here. There muſt alſo be the ſame care in training up the trees when they ſhoot; but the trelliſſes need not be made againſt theſe Walls till the trees are grown large enough to ſpread, and produce a quantity of fruit; till which time they may be ſupported by any low ordinary trellis, which will do very well till the time that the trees will have ſtrength enough to force, which will not be until the fourth or fifth year after planting, according to the progreſs they have made; for if they are forced too young, it will weaken them ſo much, as that they ſeldom make vigorous trees afterward; beſides the quantity of fruit which ſuch young trees produce, is not worth the expence and trouble of forcing; for the quantity of fuel uſed, and the trouble will be the ſame for ſmall trees, which are not capable of producing more than ſix or eight fruit each, as for thoſe trees, which may produce three or four dozen; ſo that the greater time the trees have to grow before they are forced, the better they will pay for the trouble and expence.

But it will be the beſt way not to have any of the frames made, nor the trellis, or any other of the wood-work, until the trees are ſtrong enough to force; for if theſe are done when the Walls are firſt built, as is by ſome perſons practiſed, they will be half decayed before there is any uſe for them; but then the perſons who are employed in making the trellis, muſt be very careful in putting it up, not to injure the trees.

When the trees have acquired ſtrength enough to produce a quantity of fruit, the part which is deſigned to be forced the following ſpring, ſhould be carefully pruned early in autumn, when the very weak ſhoots muſt be either entirely cut out, or pruned very ſhort, becauſe theſe, by being forced, will for the moſt part decay; and though ſome of them may be full of flower-buds, yet theſe ſhoots being weak cannot nouriſh them; ſo that the flowers having exhauſted all the ſap, the ſhoots will die ſoon after, and rarely produce any fruit, or at leaſt do not bring them to perfection. The other more vigorous ſhoots ſhould alſo be ſhortened to a proper length, after the ſame manner as is directed for thoſe trees in the open air, with this difference only, viz. that theſe which are deſigned for forcing, ſhould not have their ſhoots left ſo long, becauſe the forcing of them will weaken them; and conſequently, ſhould there be as great a length of branches, there will probably be a greater number of fruit on them; becauſe, as theſe will be ſcreened from the open air they will not be liable to blaſts, or the injuries of the froſt; and the having too many fruit on the trees will render them ſmall, and alſo too much weaken the trees; then the ſhoots ſhould be all regularly faſtened to the trellis, at a proper diſtance from each other, ſo that when the branches ſhoot the following ſpring, they may not over-hang each other. The reaſon for my adviſing theſe trees to be pruned ſo early in the ſeaſon, is, that thoſe branches which are left on, may enjoy the whole nouriſhment of the ſap, ſo that the buds will become very turgid during the winter ſeaſon, and will be prepared to open when the fires are ſet to work.

The time for beginning to make the fires is about the middle or latter end of january, according as the ſeaſon is more or leſs favourable; for if the trees are forced too early into flower, they will be in ſome danger of miſcarrying, if the weather ſhould prove ſevere; ſo that it is by much the ſureſt method to begin about the time here directed, becauſe there will be a neceſſity of admitting freſh air to the trees when they are in flower, which cannot be done ſafely when they flower in very bad weather. And thoſe trees which are forced into flower by the middle of february, will ripen their fruit as early as moſt people will deſire to eat them; for the Cherries will ripen early in april, and the Apricots by the beginning of may, and ſoon after the Plums, Peaches, and Nectarines, will be ripe.

There are ſome perſons who plant Strawberries in their borders before the fruit-trees, in order to have early fruit, which often ſucceed very well; but wherever this is practiſed, great care ſhould be taken to

Digitized by Google

keep them from ſpreading over the border, becauſe theſe plants will exhauſt the principal goodneſs of the earth, and thereby injure the trees; ſo that when it is deſigned to have Strawberries in theſe borders, I would adviſe, that the roots ſhould be either planted in pots, or ſingly at a good diſtance on a ſhady border of loamy earth, one year before they are deſigned to be forced; during which time the runners ſhould be diligently pulled off, to encourage the main roots for fruiting; and at Michaelmas theſe plants may be tranſplanted, with large balls of earth to their roots, into the borders, before the fruit-trees which are to be forced the following ſpring, ſo that they may have time to get new root before that ſeaſon; and if theſe plants are carefully watered when they begin to ſhew their flower-buds, they will produce a good quantity of fruit, which will ripen the latter end of april, or the beginning of may; but then I would alſo adviſe, that theſe plants be taken away as ſoon as they have done bearing, that they may not rob the trees of their nouriſhment.

Since I have mentioned this method of having early Strawberries, I ſhall take the liberty to inſert another method, which is often practiſed to obtain this fruit early in the ſpring, though it doth not ſo properly come under this article, which is to train up the plants either in pots or borders, after the manner before directed, for at leaſt one year or more; then in the beginning of february there ſhould be a moderate hot-bed prepared, in length proportionable to the number of plants deſigned to be forced, and the breadth ſhould be proportionable to the width of the frames which are deſigned to cover them. Theſe frames may be ſuch as are uſed for common hot-beds, to raiſe early Cucumbers, &c. This hot-bed muſt be covered with freſh loamy earth about eight inches thick, into which the Strawberry plants ſhould be placed, with large balls of earth to the roots, as cloſe as they can conveniently be planted; (for as they muſt be kept clear from runners, they will not ſpread much during the time they remain in the bed, which will be no longer than until their fruit is gone.) Then they ſhould be gently watered to ſettle the earth to their roots, which muſt be frequently repeated as the earth becomes dry, otherwiſe they will produce no fruit. While the nights continue cold, the glaſſes of the hot-bed ſhould be covered with mats, to preſerve a kindly warmth in the beds; but in the day time, when the weather is favourable, the glaſſes ſhould be raiſed to admit freſh air to the plants; for if they are too much drawn, (eſpecially when they begin to flower) they will not produce much fruit. If the ſeaſon ſhould continue long cold, and the heat of the bed ſhould decline, it will be proper to lay ſome freſh hot dung round the ſides of the beds to renew their heat, being always careful not to make them too hot, for that will ſcorch their roots and prevent their fruiting. If the plants which are planted in theſe beds are ſtrong, and in a good condition for bearing, and care be taken in tranſplanting of them to preſerve good balls of earth to their roots, as alſo to keep a due temperature of warmth in the beds, they will produce ripe fruit by the end of april, or the beginning of may, in plenty; and will continue bearing, until ſome of thoſe in the open air come in to ſucceed them.

The beſt kinds of Strawberries to plant for forcing, are the Scarlet and Alpine, for the Hautboys grow too rampant for this purpoſe.

But to return to the ſubject of hot Walls; what I have here inſerted concerning the forcing of fruits, has been only to obtain theſe fruits earlier in the ſeaſon, than they would naturally ripen againſt common Walls. But in ſome parts of England, where moſt of our good kinds of fruits ſeldom ripen, it might be very well worth while to build ſome of theſe Walls, to obtain good fruit from the beſt kinds of Peaches, Plums, &c. eſpecially in ſuch places where fuel is plenty, becauſe there the expence will not be great after the firſt building the Walls. For I would not propoſe to have coverings of glaſs, excepting for a ſmall proportion of the Walls; the reſt may have frames of canvas, or oiled paper, to ſhut over them, in the ſame manner as the glaſſes are contrived, which will ſucceed very well where proper care is taken; for as there will not be occaſion to cover theſe trees until the beginning of march, at which time alſo the fires muſt be made, ſo before the trees are in flower, the weather may be frequently warm enough to open the covers to admit ſun and air to the trees in the middle of the day; for if theſe covers are kept too cloſely ſhut, the ſhoots of the trees will draw very weak, and their leaves will turn pale for want of light and air. And as the deſign of theſe contrivances is only to bring the trees into flower three, or at moſt four weeks earlier, than they would naturally come againſt common Walls, there will be no neceſſity of making very large fires, or keeping the covers too cloſely over the trees.

Inſtead of canvas for theſe covers, oiled papers may be uſed, which ſhould be done in the manner directed for raiſing of Melons, by paſting as many ſheets of paper together, as will fit the frames on which they are to be fixed; and when the paſte is dry, the paper ſhould be faſtened into the frames, and then the oil rubbed over on the outſide with a bruſh, which will ſoak through the paper, and when the paper is dry, the covers may be uſed. This paper will laſt very well one ſeaſon, and the expence of repairing it will not be very great; wherefore theſe are to be preferred to the canvas, becauſe all ſorts of plants will thrive much better under them, than they will under canvas, or any other cloſe covering, which will not admit the rays of the light ſo well through to the plants. The frames deſigned for either canvas or paper may be made much ſlighter than thoſe for glaſs, becauſe theſe being very light, will not require ſo much ſtrength to ſupport them; and if theſe are well painted, and every year when their uſe is over, carried into ſhelter, they will laſt a long time, for they will not be wanted abroad longer than three months, viz. from the beginning of march to the end of may; for after this time the fruit will not require any covering, the trees being then full of leaves, and the young ſhoots will by that time have made ſuch progreſs, as to become a good defence of the fruit; but theſe covers ſhould not be too ſuddenly taken away, but by degrees the trees ſhould be inured to the open air, otherwiſe the change will be too great, and may occaſion moſt of the fruit to fall off, eſpecially if cold nights ſhould follow.

By this method gentlemen may be ſupplied with moſt of the beſt kinds of fruit in the northern parts of England, where without ſome ſuch care, they cannot expect much good fruit in their gardens. And as coal is in great plenty in thoſe places, the expence will be very little; therefore I am ſurpriſed that moſt of the gentlemen who live in the north, do not put this method in practice. That there are ſome few of theſe Walls built in the north is well known, but then they are chiefly deſigned to produce a little early fruit, more for curioſity than any real uſe; and theſe Walls are, for the moſt part, ſo ill contrived, that four times the fuel is expended, as will be requiſite when the Walls are built after the manner here directed; and where the heat is not pretty equally diſtributed through every part of the Wall, ſome of the trees will have too much heat, while others will have little benefit from the fires.

There are ſome perſons who build their hot Walls in ſuch a manner, as to have the greateſt heat under the border, near the roots of the trees, ſuppoſing there is a neceſſity for heat to the roots, as well as the branches; but this is a great miſtake, for the fires muſt greatly injure the roots of the trees, by drying up the moiſture of the earth, as alſo in ſcorching the tender fibres of thoſe roots which lie near them; therefore this practice ſhould not be continued, for it is much the better method to elevate the firſt flue nine inches or a foot above the level of the border, according as the ground is dry or wet, than to place it the leaſt below ground, which will only dry the earth, and not warm the air about the trees, which is the only uſe of artificial heat; for it is very commonly practiſed to draw a branch of a Vine, or other

Digitized by Google

fruit-tree, into a ſtove, which branch will produce its fruit as early as if the whole tree had been forced; when at the ſame time, all the other branches of the ſame tree, which are expoſed to the open air, will not be the leaſt forwarded, though they are all nouriſhed by the ſame root; which is a plain proof, that there is no neceſſity for adding any warmth to the roots of fruit-trees, to have their fruit earlier or better ripened.

I have alſo heard of ſome Walls which have been built for forcing of fruit, with one continued chaſm from their bottoms to the top, ſo that they have been like double Walls, with places at proper diſtances to make the fires; but theſe can be of little uſe, for if the Walls are open at their tops to let out the ſmoke, the heat will alſo eſcape with it; becauſe if the ſmoke be not led about three or four times in flues in order to warm the bricks, the heat will paſs off at the top, without doing much ſervice to the trees.

Where the Walls are planted with the beſt kinds of fruit, which are deſigned to ripen them in perfection, if the autumns ſhould prove cold, or very wet, before the fruit is ripe, it will be proper to put the covers over the trees; and if there are ſome ſlow fires made to dry off the damps, it will be of great uſe to prevent the fruit from growing mouldy, and to haſten the ripening; but when this is practiſed, the covers ſhould be taken off, whenever the weather will admit of it, that the fruit may enjoy the benefit of the free air, without which it will be inſipid or ill-taſted. Although in the former directions for forcing trees in order to have early fruit, I have adviſed, that ſuch trees ſhould have one or two years reſt in order to recover vigour, yet that is not to be underſtood of theſe trees, which are only deſigned to be brought forward enough to produce their fruit in perfection; for as the fires are not deſigned to be made till the beginning of march, the trees will not be weakened thereby, becauſe they will be inured to the open air long before their fruit is ripe, and will have time to ripen their ſhoots, and form their buds for the next year's bearing; therefore theſe trees may be thus forced every year, without doing them much injury, provided they are carefully managed.

In forcing of fruit-trees people generally hang up thermometers under their glaſſes, for the better adjuſting the heat and regulating the fires; but when this is practiſed, they ſhould be hung where the ſun can never ſhine on them, for one hour's ſun-ſhine upon the ball or tube of the thermometer, in the ſpring of the year, will ſo much rarefy the ſpirits, that they will riſe to the top of the tube, when, at the ſame time, the circumambient air may not be much more than of a temperate heat; but as the principal uſe of theſe thermometers is to regulate the fires, they are ſeldom of much uſe in the day time; becauſe if there be only one hour's ſun-ſhine in the day on the glaſſes, it will warm the air ſufficiently for the production of European fruits, without any additional heat; wherefore there will rarely be occaſion for continuing of the fires in the day, unleſs the weather ſhould prove very bad. And if, by the fires in the night, the air is warmed to the temperate point marked on the botanic thermometers, the fruit will thrive much better than in greater heat.

There are ſome perſons near London, who make it their buſineſs to raiſe early fruit to ſupply the markets, which they perform by the heat of dung only, having no fire-walls in their gardens. The method which theſe people follow, is to have a good quantity of new dung laid in a heap to warm (after the ſame manner as is practiſed for making of hot-beds.) When this dung is in a proper temperature of heat, they lay it cloſe on the back ſide of their fruit Wall; about four feet thick at the bottom, and ſloping to about ten inches or a foot thick at the top. This dung ſhould be gently beat down with a fork to prevent the heat going off too ſoon, but it ſhould not be trodden down too hard, leſt that ſhould prevent its heating. The outſide of the dung ſhould be laid as ſmooth as poſſible, that the wet may run off more eaſily; and if there is a covering of thatch, as is ſometimes practiſed, it preſerves the dung from rotting too ſoon, whereby the heat is continued the longer. The time for laying this dung to the back of the Wall is ſomewhat later than for making the fires, i. e. about the middle of february. The firſt parcel of dung will continue warm about a month or five weeks, when there ſhould be a ſupply of new dung prepared, and the old taken quite away, or mixed up with this new dung, to renew the heat, which, if it works kindly, will be ſufficient to laſt the ſeaſon. Theſe Walls are covered with glaſſes or oiled paper, in the ſame manner as the fire Walls, and the trees muſt be treated in the ſame way; but there muſt be more care taken to open the glaſſes againſt theſe Walls, whenever the weather will permit, otherwiſe the ſteam of the dung will occaſion a great dampneſs through the Wall, which, if pent in about the trees, will be very pernicious to them, eſpecially at the time they are in flower.

By this method ſome gardeners have forced long Walls filled with old well-grown fruit-trees, which have produced great quantities of fruit annually, which has well anſwered their expenſe; but as, in many parts of England, it will be very difficult to procure a ſufficient quantity of new dung for this purpoſe, therefore fire Walls are moſt uſeful, and leaſt expenſive in ſuch places.

I have ſeen in ſome places long timber fences erected to force fruit-trees, by laying new dung againſt the back ſide, in the ſame manner as is practiſed for the Walls, but theſe are by no means proper, becauſe the ſteam of the dung will eaſily get through every little crack or joint of the boards, to the great prejudice of the trees; beſides, theſe boards will continue very damp, as long as any moiſture remains in the dung, which will alſo be very injurious to them; and as theſe boards will in a few years decay, theſe will be more expenſive than Walls, if they are kept in repair for ſome years, and will never anſwer the deſign ſo well.

DESCRIPTION, *&c.*

This is a tree with a trunk from ten to twenty feet high, covered with an even unarmed bark. Branches long; branchlets round, warted by the fallen leaves. Leaves petioled, oblong, acuminate, with a blunt point, entire, ſlightly nerved, ſomewhat ſtriated, ſmooth and ſhining,

Digitized by Google

W A L

ſhining, pales beneath, membranaceous and thickiſh. Petioles ſhort, round, ſmooth. Stipules none. Panicle terminating, ſpreading: branches alternate, ſubſaſtigiate, ſubdivided, branchlets alternate, ſubterminating; flowers pedicelled, yellow, inodorous. Calyx embracing the corolla, permanent, pale coloured. Berry ſcarlet.

The calyx, corolla, genitals, and fruit have dots or glandular orange-coloured atoms ſcattered over them. The fruit, when ripe, is ſubacid and aromatic, like the other parts of the fructification. The ſeed has the flavour of the Piperitæ. It flowers ſpring and autumn. There are ſometimes male flowers, which are barren, having no piſtil[f].

Jacquin deſcribes the leaves as alternate, greaſy to the touch, brittle, five inches long. Flowers in compound racemes, (which are thyrſe-ſhaped, and two inches long), numerous, extremely ſmall, with reddiſh calyxes, and white corollas. Style double the length of the corolla.

Native of Jamaica and Hiſpaniola; Jacquin ſays on the mountain above Cape Français in Domingo; flowering in november.]

DESCRIPTIONS, &c.

1. Stem ſoft, woody, about two feet high, ſending out two or three ſide branches. Leaves alternate, of a pale yellowiſh green colour, ſoft and hairy. Flowers collected in a cloſe thick ſpike at the top of the ſtem, having ſoft hairy calyxes. Petals connected at their baſe, ſmall, bright, yellow, ſpreading.

[Stem ſuffruteſcent, branched, ſubdivided, round, hirſute. Leaves petioled, nerved, whitiſh beneath. Peduncles length of the leaves, axillary, ſolitary, erect, pubeſcent. Flowers aggregate, yellow[g].

Willdenow ſays, it reſembles the indica very much, but differs in having the teeth of the leaves ſharp and unequal, and the heads peduncled. The heads in that and the following are axillary or aggregate on a long common peduncle; in W. americana they are axillary but always peduncled, and in W. indica ſeſſile without any peduncle.

Native of South America, and the iſlands of the Weſt Indies, Braſil, Bahama, Berbices, Surinam, Jamaica, Domingo, &c.—Cultivated 1691, in the Royal Garden at Hampton Court[h].]

2. This riſes with a ſhrubby branching ſtalk to the height of eight or ten feet, and is covered with ſoft hairs. Leaves alternate, petioled, four inches long, and two inches broad in the middle, rounded at both ends, of a yellowiſh green colour, very hairy and ſoft, having ſeveral longitudinal veins. Heads axillary, ſeſſile, compoſed of cluſters of very ſmall yellow flowers, which juſt peep out of their ſoft yellow calyxes. Native of India.

3. Forſter made a diſtinct genus of this under the name of Lophanthus, from λοφος a creſt, and ανθος a flower; the flowers having under them a bracte reſembling a creſt. He allows it to be very nearly allied to this genus, and conſiders it as a ſpecies of Waltheria in his Prodromus. Native of the Marqueſas iſlands in the ſouth ſeas.

4. This is very diſtinct from the others in having roundiſh-ovate acuminate leaves, ſhaped almoſt like thoſe of the Haſell (Corylus Avellana). Heads ſeſſile, few-flowered, without bractes. Seems to be like the preceding. Native of Peru[i].]

5. Stalks woody, ſix or ſeven feet high, dividing into ſeveral branches, which are leſs hairy than thoſe of the ſecond ſort. Leaves about three inches and a half long, and an inch and half broad, of a yellowiſh green colour, not ſo ſoft as thoſe of W. indica, having many veins running from the midrib, ſtanding upon very long footſtalks. Flowers very ſmall, yellow, collected into round cluſters, ſtanding upon very ſhort peduncles, cloſe to the axils. They appear in june, july and auguſt, as the other ſorts do; and the ſeeds ripen in autumn.

[Willdenow remarks, that the whole plant is covered with a thin nap; that the leaves are ſmall, half an inch long, oblong, and blunt at each end: and that the heads are ſupported upon a very ſhort peduncle. Native of the Eaſt Indies. Mr. Miller ſays, that the ſeeds were ſent him from Campeachy.

6. This is allied to the preceding, but is more tomentoſe; the leaves are three times as long, but of the ſame breadth with the preceding; and the petals are obtuſe not retuſe. Native of the Eaſt Indies[k].]

[g] Swartz obſ. [h] Hort. kew. [k] Idem. [i] Willdenow.

PROPAGATION AND CULTURE.

These plants are propagated by seeds, which must be sown on a hot-bed; and when the plants are fit to transplant, they must be each planted into a separate small pot, and plunged into a fresh hot-bed, and afterward treated in the same manner as other tender plants of the same country, for they must be kept in the bark-stove, otherwise they will not thrive in England. The second year the plants will flower and produce good seeds, but the plants may be continued three or four years if they are often shifted, and the roots pared, to keep them within compass; for if they are permitted to remain long undisturbed in the tan-bed, their roots will run out through the holes in the bottom of the pots, and extend to a great distance in the tan; and when this happens, if their roots are torn, or cut off, the plants seldom survive it. When the plants root into the tan, they grow very luxuriant, and cannot be kept within reasonable compass; but on their roots being disturbed, their branches will hang, and their leaves shrivel up and drop off; therefore, to keep these plants within bounds, they should be drawn up out of the tan at least once in six weeks, during the summer season, and the plants shifted out of the pots once in two months; with this management the second and fifth sorts may be continued several years, but the first seldom lives longer than two years.

WATSONIA. (*So named by Mr. Miller, in honour of his learned friend William Watson, M. D. F. R. S. whose knowledge in the science of Botany, as Mr. Miller with good reason observes, justly demands this tribute.*)

Curt. magaz. t. 533. 537. *Juss.* 58.

Class. 3. 1. Triandria Monogynia.

Nat. Order of *Ensatæ.* Irides *Juss.*

GENERIC CHARACTER.

CAL. *Spathes* pressed close, mortified at top, for the most part coloured.

COR. curved back: *tube* slender: *throat* cup-cylindric: *border* six-parted, the parts spreading-regular or subbilabiate, equal or nearly so in breadth, quite equal in length.

STAM. *Filaments* three, growing to the tube, but distinct from the throat.

PIST. *Germ* inferior, triangular-cylindric. *Style* simple, filiform, erect. *Stigmas* three, slender, bifid.

PER. *Capsule* stiff-leathery, triangular-cylindric, drawn to a point at each end.

SEEDS numerous, somewhat oblong.

OBS. *Throat many times shorter, or many times longer than the border, or equal to it. Coat of the seed much bigger than the nucleus, whitish, opaque, compressed into an unequal margin. Seeds often somewhat like those of Pinus sylvestris.—In those species which have a very short throat, the margin of the seed is indistinct, the nucleus bigger than in Gladiolus.* Gawler.

ESSENTIAL CHARACTER.

Cor. six-parted, spreading or subbilabiate, equal. *Stigmas* three, bifid. *Caps.* triangular-cylindric, attenuated at each end.

Antholyza Merianella. *Dict. nostr. n.* 6.
Leaves narrower vertically ensiform strict twisted a little, spathe tube throat and border equal, pistil nearly equal to the segments which are acute alike and regularly spreading.

DESCRIPTIONS, &c.

[The root in this elegant genus is tuberous-tunicated, hemispherical, toothed at the edge. Scape very stiff, frequently inclined to woody, simple, or little branched. Leaves

Digitized by Google

W A T

Leaves enſiform, attenuated at each end, often ſhining. Flowers in looſe terminating ſpikes. Spathes one-flowered. All the ſpecies are natives of the Cape of Good Hope, and flower late in the ſummer, or in the autumn [1].

1. This is readily diſtinguiſhed from the other ſpecies by the form of the corolla, which ſtrongly reſembles ſome ſpecies of Aletris, Lachenalia, and Aloe: the alternate ſegments are interior. Bulb compreſſed and tunicated.

It is very ſubject to vary: having either a ſimple ſcape ſix or eight inches high, with three or four diſtant flowers, ſometimes one-ranked; or a three or four-branched ſtem two feet high, with a terminating ſpike of from twenty to thirty cloſely imbricated diſtich flowers, and appreſſed ſpikelets in proportion. The ſame bulb will one year produce pale pink, the next deep crimſon, and the following variegated or ſtriped corollas, always ſcentleſs. One of theſe varieties is figured in Curtis's Botanical Magazine, t. 441. under the name of Antholyza Merianella. But the real Antholyza Merianella of Linneus, or Gladiolus Merianellus of Thunberg is a different plant, having pubeſcent leaves, fewer in number, nearly ſheathing the whole ſtem; flowers differently formed, with larger and rounder ſegments; ſtigmas entire and complicate: in fact it is a Gladiolus, nearly allied to G. hirſutus in leaf, and to G. Watſonius in its tubular throat.

Jacquin has given a good figure of one of the varieties, but has erroneouſly deſcribed it as having a three-valved ſpathe.

This ſpecies was probably introduced in 1778.

2. Leaves linear-enſiform, ſmooth, ſhorter than the ſtem, and ſomewhat twiſted at the baſe. Scape rather flexuoſe, with two or three ancipital ſpathe-like leaves, and ſimple; but ſince all the plants of this order which have ſpathaceous ſtem-leaves are ſubject to branch, it may probably be ſometimes polyſtachyous. Spathes green, ſphacelate or mortified towards the point, keeled, and much ſhorter than the tube. Corolla about three inches long: tube widening gradually into the throat, and joined by a geniculate curvature: ſegments as long as the throat, margins of the alternate ones ſlightly revolute. Stamens cloſely accumbent: anthers deep blue. Style projecting nearly equal to the ſegments. Bulb ſmaller than in many of its congeners and roundiſh.

The length of the tube relative to the faux or throat, is the permanent ſpecific diſtinction; although Jacquin deſcribes the ſegments, faux, and tube, as of equal length, his own figure ſhows his miſtake. As ſome authors ſpeak of theſe flowers as having a double tube, it may not be amiſs to obſerve, that the part only to which the filaments are joined is called the tube; where theſe become free the faux or throat begins, and extends to the baſe of the ſegments of the limb or border. Imported by Meſſrs. Grimwood and Wykes, about 1800. Mr. Alderman Hibbert poſſeſſes a variety with deep purple flowers, but with the mouth always of a ſtill deeper colour within.

3. Bulb compreſſed, generally reniform. Radical leaves four to ſeven, enſiform, attenuated at each end, ſmooth, ſhining, ſlightly edged, equitant at the baſe, midrib prominent: ſtem-leaves conduplicate, gradually ſhorter. Stem two or three times longer than the leaves, ſomewhat woody, ſtrict, round, from three to ſix feet high, with ſeveral upright branches all ſpike-bearing. Spikes looſe, the primary one ten to twenty-flowered; flowers ſpringing from oppoſite ſides, when fully expanded inclining to the ſame front; colour (of β.) bright ſcarlet; ſcent none. Spathes green below, ſphacelate and red upwards, ſhorter than the tube, which is about the length of the throat, and that again of the border; ſegments nearly equal, narrowed at their baſes, ſomewhat ſharp, the alternate ones rather more ſo. Parts of fructification prominent, nearly equal to the corolla, and equal among themſelves. Anthers dark violet. It is the talleſt of the genus yet known to us. Blows freely towards the end of ſummer, with a ſucceſſion of bloom for a month or longer. It ſeeds and produces offsets in abundance. Both varieties are now common in the nurſeries about London. They agree in every thing except in the colour of the leaf and corolla.

Jacquin, in his Icones plant. rar. has united two very diſtinct ſpecies as varieties, namely variety α of the preſent ſpecies, figured in his 234th plate; and Gladiolus marginatus δ of Thunberg (Watſonia roſea *Herb. banks.*) in his 235th plate.

4. Leaves four, oblong, enſiform, diſtich, very ſhort, ſmooth and ſhining, mucronate, with a filiform cartilaginous edging. Stem ſtraight, branched, from ſix inches to a foot high. Spathe green, broad, upright, conduplicate, embracing, at the end truncately ſubacute, ſphacelate, and coloured. Corolla recurved, regular, patent: faux or throat narrow-turbinate: ſegments nearly obovate, ſhortly pointed, the inner ones almoſt twice as broad as the others, flat, the outer ones laterally ſubrevolute. Parts of fructification declined, aſſurgent: Segments of the ſtigmas ſhort, revolute, extending rather beyond the anthers. Corolla micaceous, glittering very much in the ſun; its colour not to be repreſented by art. It flowers about may, and is ſcentleſs. Imported by Meſſrs. Kennedy and Lee.

5. Bulb compreſſed, ſubreniform. Leaves lanceolate, ſubcoriaceous, nerved, far ſhorter than the ſtem, edged with a very thick browniſh cartilage. Stem round, ſtrict, woody at the baſe, gracileſcent upwards appreſſedly polyſtachyous, from three to four feet high. Flowers numerous, cloſe ſet, diſtichly ſubimbricate, diffuſing a kernelly ſmell ſomething reſembling that of Heliotropium peruvianum. Spathes green at the baſe, ſphacelate upwards. Corolla ſalver-ſhaped, nodding: tube recurved: faux twice ſhorter than the tube; cyathiform-turbinate, with ſix lamellous appendicles on the inſide alternating with the ſtamens: ſegments elliptic, the interior ones ſomewhat broader. Filaments ſemicolumnar, upright: anthers ſagittate, yellow, ſurrounding the ſtyle, not parallel.

Thunberg enumerates four varieties—α white—β pale red—γ blood-coloured—δ purple. α ſeems to be this plant—β Watſonia breviſolia—γ W. iridifolia β—δ W. roſea. He found them on the ſummits of the Table and other high mountains, and on hills below the mountains from Cape Town to Houteniquas-Land, growing among the graſs in ſuch abundance, that whole hills appeared as if covered with a beautiful ſcarlet carpet.

Introduced into Kew garden by Mr. Maſſon in 1774. It flowers in july or auguſt, and is known among the nurſerymen under the name of Ixia Sceptrum. Owing to the intimate union of the ſpikelets with the main ſtem it appears as if it began to flower at the middle, but on examination, will be found to begin at the baſe of the primary ſpike, as is uſual with its congeners. For Thunberg's deſcription, ſee Gladiolus marginatus.

6. This is one of the ſmaller ſpecies, the Cape ſpecimens being from eight inches to a foot high, and the leaves about the third of an inch broad, linear and ſhorter than the ſtem. Corolla, of one uniform colour, recurved, in Jacquin's figure refracted. Spathe acute. Faux a complete cylinder. Segments quite regular, oblong-ovate, acute. Anthers above the faux below the ſtigmas. In the primary ſpike from four to ſix flowers. It differs from W. roſeo-alba in a proportionably ſhorter tube; from W. Meriana in a regularly and recurvedly ſpreading border; from W. iridifolia in a proportionably longer ſpathe, quite regular border, and equal ſegments. It flowers in may [2]. For Mr. Miller's deſcription, &c. ſee Antholyza Merianella; but this is not the A. Merianella of Linneus. See n. 1.

PROPAGATION AND CULTURE.

See ANTHOLYZA.

3. Requires a biggiſh and very deep pot, light earth, and plenty of water after it has ſhown the flowering ſtem. It produces ſeeds and offsets in abundance.

4. Is yet a rare plant, though it may be increaſed with the uſual facility of the genus.

[1] Gawler in Curt. mag. and Juſſ. gen.

[2] Curt. magaz.

Digitized by Google

5. This increaſes rapidly both by ſeeds and offſetts, and is now one of the commoneſt of its tribe. It requires a very deep pot [n].

1. This is a ſhrub of the human ſtature. Stems and branches round, aſh-coloured, knobbed; wood white, yellow towards the middle. Leaves or petioles an

[n] Curt. magaz.

inch long, of a cloſe texture, flat, dark green and ſhining above, paler beneath; having a ſomewhat aſtringent bitter taſte and a pleaſant ſmell. Flowers whitiſh, becoming yellow with age. Segments of the corolla five or ſix. Berries ſmall, hard, round, reſembling thoſe of the Bay, black when ripe. Seeds about ſeven or eight, in two rows along the partition [o].

Native of Malabar and Ceylon.

2. This is a tree with round pubeſcent branches. Leaves oppoſite, petioled, obtuſe, quite entire and very ſmooth, ſhining above, ſtiff, ſimply veined. Cymes convex. Peduncles pubeſcent. Corolla twice as ſmall as in the preceding. Style much longer than the corolla. Stigma headed-two-lobed. Berry the ſame ſize as that of Juniper. Native of the Eaſt Indies [p].

3. Trunk ſcarcely any, but branches innumerable; the ſmall ones regularly croſs-armed, and ſpreading. Thorns ſimple, oppoſite, above the axils, ſpreading, croſs-armed, very ſtrong, and very ſharp: in luxuriant plants they are ſometimes three-cleft. Leaves on the young ſhoots oppoſite, on the elder branchlets faſcicled, ſhort-petioled, reflected, ovate, entire, ſmooth, various in ſize. Stipules connecting, awl-ſhaped. Umbellets (cymes) oppoſite, below the thorns, ſmall, about the length of the leaves. Peduncle and pedicels ſmooth, round. Flowers ſmall, yellow. Calyx four-toothed. Tube of the corolla bellied, ſhort; mouth downy; border four-parted; ſegments ovate, expanded. Stamens four in the mouth of the corolla: anthers ovate. Germ globular: ſtigma headed. Fruit an obcordate drupe, compreſſed a little, with a hollow on each ſide, ſize of a cherry, crowned with the remaining calyx, fleſhy, ſmooth, yellow, two-celled: in each cell one oblong, one-celled nut.

This is one of the moſt common ſcraggy thorny buſhes, on the coaſt of Coromandel, every ſoil and ſituation ſuiting it. Flowers in the hot ſeaſon, and makes excellent fences.

The ripe fruit is eaten by the natives; the leaves are eaten generally in curries: on both accounts this ſhrub has the additional name of Kura, which means eſculent. The Telingas call it Balluſoo-Kura [q].

WEBERA. See *Bryum* and *Buxbaumia.*

WEDELIA. (*From John Wolffg. Wedel, phyſician at Jena: author of* Tentamen Botanicum 1747 & 1749.)—See *Allionia* & *Polymnia.*

WEEDS, are all plants noxious in gardening or agriculture. Many plants which are uſeful, are Weeds in a relative ſenſe, becauſe they are out of their proper place, or occupy the room of ſtill better things.

A catalogue of the principal Weeds which infeſt gardens, arable lands and paſture grounds is here given; diſtinguiſhing the annual from the perennial, becauſe the methods of extirpation are different.

Annual Weeds infeſting Gardens and Arable Lands.

Veronica agreſtis. *Procumbent Speedwell,* or *Germander Chickweed.* April to ſeptember.

Veronica arvenſis. *Wall Speedwell,* or *Speedwell Chickweed.* May.

Veronica hederifolia. *Ivy-leaved Speedwell,* or *ſmall Henbit,* in Norfolk, *Winter-weed.* April to ſeptember.

The above are ſmall plants, ſeeding abundantly, but eaſily deſtroyed by the hoe.

Alopecurus agreſtis ſ. myoſuroides. *Slender* or *Field Fox-tail* or *Mouſe-tail Graſs.* July. Common in ſome arable lands, and eaſily known by its upright growth and very ſlender ſpike. I am not abſolutely certain that it is annual.

Agroſtis Spica venti. *Silky Bent-graſs.* June and july. Among corn in light moiſtiſh lands, but not very common.

Poa annua. *Annual Meadow-graſs.* An excellent ſweet Graſs in paſtures, but a troubleſome weed in gardens; flowering and ſeeding during a great part of the year.

Bromus arvenſis. *Field Brome-graſs.* July.

[o] Hort. malab. [p] Willdenow. [q] Roxburgh.

Digitized by Google

W E E

Bromus ſterilis. *Barren Brome-graſs.* June and july.

Avena fatua. *Wild Oats* or *Haver.* Auguſt. Fallowing, hoeing and hand-weeding are the only means of extirpation.

Lolium temulentum. *Bearded* or *annual Darnel Graſs*, or *Droke.* July.

Hordeum murinum. *Wall Barley-graſs*, *Mouſe Barley graſs*, *Way-Barley*, *Way Bennet*, or *Bent. Pick purſe.* The whole ſummer.

Hordeum maritimum. *Sea Barley-graſs* or *Squirrel-tail Graſs.* June and july. Said to be notorious for ſticking in the gums of horſes.

Several other Graſſes are bad weeds in cultivated land. Some of theſe will be found among the Perennials.

Sherardia arvenſis. *Little Field Madder.* May through the ſummer.

Galium tricorne. *Corn Bedſtraw*, or *Three-flowered Gooſe Graſs.* Among Tares, &c. July.

Galium Aparine. *Gooſe-graſs*, or *Goſling-graſs*, *Cleavers*, *Catchweed*, or *Scratchweed*, *Hairof* or *Hair-rough.* May to auguſt.

Alchemilla arvenſis. *Field Ladies Mantle*, *Parſley Piert.* May through the ſummer.

Sagina apetala. *Small-flowered Pearlwort or Chickweed Breakſtone.* Common in ſandy ſoils on walls, walks, &c. May and june.—This ſmall weed infeſts gravel walks, and if ſuffered to ſeed will increaſe prodigiouſly and grow very troubleſome.

Sagina erecta. *Upright Pearlwort.* May. In paſtures and heaths among barren ſand and gravel.

Myoſotis ſcorpioides. *Mouſe-ear Scorpion-graſs.* The whole ſummer. Dry fields. A handſome large variety, that ſeems to be perennial, is common in water.

Lithoſpermum arvenſe. *Corn Gromill*, *Baſtard Alkanet*, *Baſtard Gromill* or *Gromwell* (Gray Millet), *Salfern*, or *Stony-hard.*

Lycopſis arvenſis. *Small Bugloſs.* June.

Anagallis arvenſis. *Pimpernel.* June.

Campanula hybrida. *Corn Bell-flower*, *wild Venus's Looking-glaſs*, or *codded Corn-Violet.*

Viola tricolor. *Panſies* or *Heart's eaſe.* May to ſeptember.

Solanum nigrum. *Common* or *Garden Nightſhade.* June to ſeptember. In gardens and on dunghills.

Chenopodium urbicum—rubrum—album—ficifolium polyſpermum. The *Gooſefoots* flouriſh on dunghills, and hence have the name of *Muckweed.* From their ſucculency they are called *Fat-hen.* Mr. Marſhall ſays he has heard Red Gooſefoot called *Drought-weed.* July to ſeptember. Theſe and other ſucculent weeds are often ſuffered to occupy dunghills unmoleſted, and muſt exhauſt the dung very much.

Cuſcuta europæa. *Great Dodder.* On beans, hops, nettles, thiſtles, &c.

Cuſenta Epithymum. *Small Dodder.* On heaths, thyme, &c.

Theſe plants flower in auguſt, and are indifferently called *Hell-weed*, *Devil's Guts* and *Scald.*

The former frequently ſtrangles crops of beans. The latter killed much of my Lucern laſt year.

Bupleurum rotundifolium. *Thorow-wax.* July. Chalky fields.

Caucalis latifolia. *Great* or *broad Bur Parſley.* July.

Caucalis Anthriſcus. *Upright Hedge Parſley.* July. Hedges and Balks.

Caucalis infeſta. *Spreading Hedge Parſley.* July.

Caucalis nodoſa. *Knotted Stone Parſley.* May and june.

Siſon ſegetum. *Corn Honewort.* Auguſt.

Æthuſa Cynapium. *Small Hemlock*, *thin-leafed wild Hemlock* or *Fool's Parſley.* July and auguſt. Common in gardens.

Scandix Pecten Veneris. *Shepherd's Needle*, *Beggar's Needle*, *Crake-needle*, *Needleweed*, *Venus's Comb.*

Polygonum aviculare. *Knot-graſs*, *Hogweed.* From april to october. Remarkably full of ſeed, and propagates itſelf abundantly, both in graſs and arable fields, eſpecially where the ground is much trodden. Small birds are very fond of the ſeed, and hogs of the herb.

Polygonum Convolvulus. *Climbing Buckwheat*, *Corn-bind*, or *Black Bindweed.* June and july.

Saxifraga tridactylites. *Rue-leaved Saxifrage.* May.

Scleranthus annuus. *Annual Knawel* or *German Knot-graſs.* July. Sandy fields.

Stellaria ſ. Alſine media. *Common Chickweed.* The peſt of gardens, flowering and ſeeding almoſt all the year; ſupplying conſtant food to ſmall birds.

Arenaria rubra. *Purple Sandwort* or *Spurrey.* July and auguſt. In ſandy fields.

Agroſtemma Githago. *Cockle* or *Popple.* June and july.

Spergula arvenſis. *Corn Spurrey*, *Sandweed* or *Pick-purſe.* July and auguſt. Cultivated in ſandy ſoils on the Continent.

Euphorbia Peplus. *Petty Spurge.* July and auguſt.

Euphorbia exigua. *Dwarf Spurge.* July.

Euphorbia helioſcopia. *Sun Spurge*, *Wartwort* or *Wretwort.* July and auguſt. The firſt and laſt very common in gardens: the ſecond in corn.

Papaver Rhoeas. *Red Poppy*, *corn Poppy*, *corn Roſe*, *cup-Roſe*, *Redweed*, or *Cankerweed.* June and july.—Other Poppies, as P. Argemone or *Long rough-headed Poppy*, and P. dubium or *Long ſmooth-headed Poppy*, are found among corn, but not ſo common. Their flowers are much ſmaller and paler.

Delphinium Conſolida. *Field Larkſpur.* This has increaſed ſo much in Cambridgeſhire, as to become one of the common weeds among corn. June and july.

Adonis autumnalis. *Corn Adonis-flower*, *Pheaſant's-eye*, *red Maithes*, *Red Morocco.* Frequent in ſome corn fields of Kent. May to october.

Ranunculus arvenſis. *Corn Crowfoot.* June. Very common among corn. Known by the paleneſs of its leaves and flowers, and the pricklineſs of the ſeeds; which do not uſually vegetate till the ſecond year after ſowing.

Lamium purpureum. *Red Archangel* or *Dead Nettle.* Common in gardens. May.

Lamium amplexicaule. *Henbit Archangel* or *Great Henbit.* February to june. Sandy fields.

Galeopſis Ladanum. *Red Hemp-Nettle.* Auguſt and ſeptember. Dry fields, eſpecially in a calcareous ſoil.

Galeopſis villoſa. *Downy Hemp-Nettle.* July and auguſt. Northern counties and Wales, ſandy fields.

Galeopſis Tetrahit. *Common Hemp-Nettle.* July and auguſt.—In Yorkſhire called *Dea-nettle.* Marſhall.

Galeopſis verſicolor. *Large-flowered Hemp-Nettle*, or *Bee-Nettle.* July and auguſt. Sandy fields in the north, and in Norfolk.

Stachys arvenſis. *Corn Woundwort* or *round Ironwort.* July and auguſt. Common in gravelly and calcareous ſoils.

Thymus Acinos. *Baſil Thyme* or *ſmall wild Baſil.* July and auguſt. Sandy or calcareous ſoils.

Antirrhinum ſpurium. *Round-leaved Fluellin.*

Antirrhinum Elatine. *Sharp-leaved Fluellin.* Both from july to ſeptember.

Antirrhinum minus. *Leaſt Snapdragon.* June to auguſt. Sandy fields.

Antirrhinum Orontium. *Leſſer Snapdragon.* July and auguſt. Sandy and calcareous fields.

Draba verna. *Common Whitlow-graſs.* March and april. A very ſmall weed, common in dry paſtures, walls, banks, gravel-walks, pavements, &c.

Alyſſum (or Myagrum) ſativum. *Gold of Pleaſure.* June. Among flax.

Thlaſpi arvenſe. *Penny Creſs* or *Smooth Mithridate Muſtard.* June and july.

Thlaſpi campeſtre. *Common Cow-creſs* or *Mithridate Muſtard.*

Thlaſpi Burſa Paſtoris. *Common Shepherd's Purſe.*

Sinapis nigra. *Common Muſtard.* In ſome diſtricts takes the place of the next.

Sinapis arvenſis. *Wild Muſtard*, *Charlock*, *Chadlock*, *Cadlock*, *Catlock*, or *Wild Rape.* May.—Sinapis alba and nigra, *White* and *Common Muſtard*, are alſo found wild among corn.

Raphanus Raphaniſtrum. *Wild Radiſh* or *jointed Charlock.* June and july. Diſtinguiſhed from the preceding by its pale yellow or white flowers, and by its round ſmooth jointed pod. The plant is covered with bent pellucid briſtles.—In Yorkſhire theſe weeds are called *Runſh.*

Theſe

Digitized by Google

These two plants are a disgrace to the spring crops in many parts of the country. Women and children are employed to hook them, but ineffectually; sometimes a scythe is run over them to cut off the flowering top; and sheep are frequently turned into the bean crop to eat the Charlock. The sheep will sometimes eat the beans, but upon the whole they do more good than harm.

Geranium dissectum. *Jagged-leaved Crane's-bill.* May and june. On fallows.

Geranium columbinum. *Long-stalked Crane's-bill.* June and july. Gravelly and calcareous soil; not common.

Fumaria officinalis. *Common Fumitory.* April or may to august.

Lathyrus Aphaca. *Yellow Vetchling.* June to august. Not uncommon in the corn fields of Cambridgeshire.

Ervum tetraspermum. *Smooth Tare,* or *Tine Tare* with smooth pods. June.

Ervum hirsutum. *Hairy Tare, small wild Tare,* or *Tine Tare.* June.

Trifolium officinale. *Common Melilot.* June and july. A bad weed among wheat.

Trifolium arvense. *Hare's-foot Trefoil.* July and august. Sandy soils.

Sonchus oleraceus. *Common Sowthistle* or *Swinethistle,* both smooth and prickly; the latter is sometimes called *Boarthistle.* July to september. Common in gardens.

Lapsana communis. *Nipplewort.* Common in gardens. June and july.

Carduus nutans. *Musk Thistle.* July and august. Common on fallows in gravelly and calcareous soils. Easily known by its handsome nodding heads, and the musky smell of the flowers, like sweet sultan.

Gnaphalium germanicum. *Common Cudweed.* July and august. In barren gravel.—G. gallicum or *Narrow-leaved Cudweed:* and G. minimum or *Least Cudweed* are also found in the same sort of soil.

Senecio vulgaris. *Common Groundsel* or *Simson.* In flower almost all the year. No weed is more common in gardens and on fallows.

Chrysanthemum segetum. *Corn Marigold, Yellow Ox-eye, Golden Corn-flower, Yellow Buddle.* June to august. The pest of light sandy soils. It is said not to be fond of dung; and that in Denmark there is a law for the extirpation of it.

Pyrethrum (or Chrysanthemum) inodorum. *Corn Feverfew* or *scentless Mayweed.* August and september. Chiefly in a gravelly soil.

Matricaria Chamomilla. *Wild Chamomile.* May to july. Common among corn and on dunghills about London.

Anthemis arvensis. *Corn Chamomile.* Among corn, especially in a gravelly soil. June and july. The herb has little scent, but the flowers are sweet.

Anthemis Cotula. *Stinking Mayweed* or *Chamomile.* June and july. Too common among corn, known by the names of *Mayweed* or *Maithes,* and in Yorkshire *Dog finkle.* Frequently confounded with the three preceding; but this is much the worst weed, and is so acrimonious as to affect the hands of those who pull it up.

Centaurea Cyanus. *Corn Blue-bottle, Boddle* or *Buddle,* which are merely corruptions of *Bottle. Blue-Bonnet.* July and august.

Urtica urens. *Small Stinging Nettle.* June to october. Common in gardens.

Amaranthus Blitum. *Small Garden Blight* or *Wild Amaranth.* August. In gardens and on dunghills, but not very common.

Mercurialis annua. *Annual Mercury.* July to september. In gardens.

Atriplex patula. *Spreading Halbert-leaved Orache.* June to august.

Atriplex angustifolia. *Spreading narrow-leaved Orache.* June to august.

These are found with the Chenopodiums or Goosefoots in gardens and on dunghills.

More annual plants might have been added as Weeds, but they are either not common enough, or too inconsiderable to deserve notice as such. Several of the above can hardly be reputed as very noxious. Most of them may be destroyed easily, in gardens by hoeing, and in arable lands by ploughing. Wild Oats, Poppy, the Charlocks, and Mayweed, have so filled the ground of the slovен, that they cannot be got rid of without assiduous culture, and frequent fallowing.

Annual Weeds in Meadows and Pastures.

Jasione montana. *Sheep's-bit* or *Sheep's Scabious.* June and july. Dry sandy pastures and heaths.

Chironia (or Gentiana) Centaurium. *Common Centaury.* July and august. Dry pastures.

Gentiana Amarella. *Autumnal Gentian.* August. In calcareous pastures.

Gentiana campestris. *Field Gentian.* September. High Pastures, in a gravelly or calcareous soil.

Linum catharticum. *Purging Flax* or *Mill Mountain.* June to august. Dry pastures.

Juncus bufonius. *Toad Rush.* Wet pastures and marshes. July and august.

Peplis Portula. *Water Purslane.* July and august. Marshes and wet heaths.

Polygonum aviculare. *Knot-grass.* See Arable weeds.

Cerastium vulgatum. *Broad-leaved Mouse-ear Chickweed.* April and may.

Cerastium viscosum. *Narrow-leaved Mouse-ear Chickweed.* May to september.

Cerastium semidecandrum. *Little Mouse-ear Chickweed.* March and april.

Bartsia (or Euphrasia) Odontites. *Red Bartsia* or *red Eyebright.* July and august.

Rhinanthus Crista-galli. *Yellow Rattle* or *Cock's-comb. Penny-grass* or *Penny-weed.* In Yorkshire *Heny-penny.* June. Moist meadows. This weed keeps its ground, for the seeds are ripe at the time of cutting grass for hay.

Euphrasia officinalis. *Eyebright.* July to september. Dry pastures and heaths.

Draba verna. *Common Whitlow-grass.* Dry pastures. See Arable weeds.

Geranium molle. *Dove's-foot, Crane's-bill.* April to august.

Geranium rotundifolium. *Round-leaved Crane's-bill.* June and july.

Geranium dissectum. *Jagged-leaved Crane's-bill.*

Lathyrus Nissolia. *Crimson Grass-vetch.* May.

Ornithopus perpusillus. *Common Bird's-foot.* May. Sandy pastures.

Trifolium subterraneum. *Subterraneous Trefoil.* May. Barren pastures and heaths.

Trifolium scabrum. *Rough-Trefoil.* May and june. Chalky and sandy fields.

Trifolium glomeratum. *Round-headed Trefoil.* June. Gravelly pastures; not common.

Trifolium striatum. *Soft knotted Trefoil.* June. Dry barren pastures.

Medicago polymorpha. *Heart Medick, Clover* or *Trefoil.* May and june.

These five plants are hardly to be considered as weeds, for cattle will eat them, but they are not cultivated. The last species is found commonly mixed with Clover, particularly with black Medick, Trefoil or Nonesuch. Its prickly seeds make it not to be so good for cattle, if it should stand long enough to produce them. It is easily distinguished by the spots upon the leaves, as well as by its seeds.

Crepis tectorum. *Smooth Succory-Hawkweed.* June to september. Dry pastures, walls and roofs.

Gnaphalium germanicum. *Common Cudweed.* July and august. Barren gravelly pastures.

Inula pulicaria. *Small Fleabane.* September. Sandy inundated meadows or heaths.

Centaurea Calcitrapa. *Star-thistle.* July and august. Dry pastures and by way sides.

Annual weeds in pastures are neither so numerous nor so destructive as those on arable land; many of them are insignificant, and many others are eaten by the cattle along with the herbage.

Biennial Weeds in Corn.

Echium vulgare. *Viper's Bugloss* or *Cat's-tail.* June and

Digitized by Google

and july. It infeſts corn very much every third year in ſome counties.

Pieris hieracioides. *Hawkweed Ox-tongue.* July and auguſt.

Carduus lanceolatus. *Spear Thiſtle,* in ſome places *Boar-thiſtle,* or *Bur-thiſtle.* June to ſeptember.

Onopordum Acanthium. *Cotton Thiſtle.* July.

Theſe Thiſtles, with many other ſpecies, and various kinds of weeds with downy ſeeds, are ſuffered to remain untouched on banks, way-ſides and fallows, in order to ſerve as a nurſery for a conſtant ſupply of weeds. If the waſte places were to be run over with a ſcythe once a year, this evil would ſoon be prevented.

Biennial Weeds in Paſtures.

Daucus Carota. *Wild Carrot, Bird's-neſt* or *Bee's-neſt.* June and july.

Heracleum Sphondylium. *Cow Parſnep, Meadow Parſnep,* or *Madnep.* July.

Paſtinaca ſativa. *Wild Parſnep.* July. This grows chiefly in a calcareous ſoil. The flowers are yellow; thoſe of the preceding ſpecies are white, and that is a much larger plant.

Carum Carui. *Caraway.* June. This is commonly reputed to be biennial; but I have many plants which I ſowed in my garden, now in the fourth year of their life.

Tragopogon pratenſis. *Yellow Goat's-beard.* June.

Tragopogon porrifolius. *Purple Goat's-beard.* Moiſt Meadows. Not common. May and june.

Crepis fœtida. *Stinking Hawkweed* or *Hawk's-beard.* June and july. Dry chalky paſtures. Not common.

Crepis biennis. *Rough Succory-Hawkweed,* or *Rough Hawk's-beard.* Chalky paſtures. June and july.

Carduus paluſtris. *Marſh Thiſtle* or *Red-thiſtle.* July and auguſt. Common in wet meadows.

Carduus eriophorus. *Woolly-headed Thiſtle.* Auguſt. Calcareous ſoil.

Carlina vulgaris. *Common Carline Thiſtle.* June. Dry ſandy paſtures.

Conyza ſquarroſa. *Ploughman's Spikenard.* July and auguſt. Calcareous ſoil.

Erigeron acre. *Blue Flea-Bane.* July and auguſt. Gravelly and calcareous paſtures.

Perennial Weeds in Corn.

Agroſtis ſtolonifera. *Creeping Bent-graſs,* or *running Quich* or *Twitch.* July and auguſt.

Holcus mollis. *Creeping Soft-graſs,* in Yorkſhire *White-graſs.* July and auguſt.

Feſtuca duriuſcula. *Hard Feſcue-graſs, Black Quich, Twitch* or *Couch.* Marſh. Gloc.

Triticum repens. *Creeping Wheat-graſs, Dog's-graſs, Quick, Quich, Twitch, Whicks, Couch.* June to ſeptember. As every bit of this deteſtable weed will grow, it is rather increaſed than checked by common ploughing and digging; nor is there any way of deſtroying it effectually, but by deep and frequent ploughings, picking it out and burning it.

Scabioſa arvenſis. *Field Scabious* or *Great Bluecaps.* July.

Convolvulus arvenſis. *Small Bindweed* or *Corn-bind.* June and july.—Its roots ſpread deep and wide, and every piece of them will grow; it is no eaſy matter to eradicate this pernicious plant.

Silene inflata ſ. Cucubalus Behen. *Bladder-Campion* or *Catchfly, White Corn Campion, Spattling Poppy* or *Frothy Poppy, White Bottle,* or *White Ben.* July.

Lychnis dioica. *Wild White Campion.* May to ſeptember. I never ſaw the Red Campion in a corn field.

Ceraſtium arvenſe. *Field Chickweed.* May to auguſt.

Rubus cæſius. *Small Bramble* or *Dewberry.* June and july.

Potentilla anſerina. *Silver-weed* or *wild Tanſy.* June and july; in moiſt furrows.

Mentha arvenſis. *Corn Mint.* June to ſeptember. It is ſaid that this herb will prevent milk from curdling, and that when hungry cows have been put into a field, after harveſt, where this plant abounds, it has been ſcarcely poſſible to turn the milk for cheeſe.

Glechoma hederacea. *Ground Ivy, Gill, Ale-hoof, Tun-hoof.* April and may. On fallows, as well as among buſhes and under hedges.

Lamium album. *White Archangel* or *Dead Nettle, Dea Nettle.* In gardens, and under hedges, as well as in paſtures.

Orobanche elatior. *Tall Broom-rape.* July and auguſt.

Orobanche ramoſa. *Branched Broom-rape.* Auguſt and ſeptember.

Malva ſylveſtris. *Common Mallow.* May to auguſt.

Ononis arvenſis. *Corn Reſt-harrow* or *Cammock, Petty Whin* or *Ground Furze.* June to auguſt.—The roots matting together with great ſtrength, are very troubleſome where land is to be ploughed for corn. This property however makes it an excellent plant to ſet on ſea and fen banks, to keep them firm and compact.

Sonchus arvenſis. *Corn* or *Tree-Sowthiſtle* or *Swine-Thiſtle.* Auguſt.

Leontodon Taraxacum. *Common Dandelion.* April to july.

Carduus arvenſis. *Way Thiſtle, Corn Thiſtle* or *Creeping Thiſtle.* July. The only common Thiſtle that is perennial. The fallows in ſtrong lands, and the way ſides are commonly full of it. The downy ſeeds are carried a long way by the wind, and it is not eradicated without great difficulty.

Tuſſilago Farfara. *Colt's-foot.* March and april. On wet fallows.

Chryſanthemum Leucanthemum. *Great White Ox-eye.* June and july.

Centaurea Scabioſa. *Great Knapweed* or *Knob-weed, Great Horſe Knobs, Matfellon* or *Bulweed.*

Equiſetum arvenſe. *Corn Horſetail* or *Snake-pipe.* March and april. In a wet ſoil.

Perennial Weeds in Meadows and Paſtures.

Veronica officinalis. *Male* or *common Speedwell.* May and june. Dry paſtures and heaths.

Veronica ſerpyllifolia. *Smooth Speedwell* or *Paul's Betony.* May and june.

Veronica Chamædrys. *Germander Speedweed* or *wild Germander,* or *Bird's-eye.* May.

Salvia verbenaca. *Wild Engliſh Clary.* June to october.

Valeriana dioica. *Small* or *marſh Valerian.* June. Wet meadows and marſhes.

Valeriana officinalis. *Great wild Valerian.* June. Hedges and dry paſtures.

Schoenus compreſſus. *Compreſſed Bog-ruſh.* July. In ſpongy meadows as well as bogs.

Scirpus cæſpitoſus. *Scaly-ſtalked Club-ruſh.* July. Boggy heaths.

Scabioſa ſucciſa. *Devil's-bit Scabious* or *Blue-caps.* Auguſt to october.

Scabioſa columbaria. *Small Scabious.* June and july. Gravelly and calcareous paſtures.

Aſperula cynanchica. *Squinancy-wort,* or *ſmall Wood-ruff.* June. Open calcareous paſtures.

Galium ſaxatile. *Smooth heath Bedſtraw.* July and auguſt. Heaths and mountain paſtures.

Galium uliginoſum. *Rough marſh Bedſtraw.* Auguſt. Wet meadows.

Galium erectum. *Upright marſh Bedſtraw.* June and july. Moiſt Meadows.

Galium verum. *Yellow Ladies Bedſtraw,* or *Cheeſe-rening.* July and auguſt. Common in dry paſtures. It does not ſeem that this plant will coagulate milk; it is probably put into rennet to give it a flavour.

Plantago major. *Great Plantain,* or *Way-Bread.* June through the ſummer.

Plantago media. *Hoary Plantain.* In a calcareous or gravelly ſoil.

Plantago lanceolata. *Ribwort Plantain, Cock's-heads,* or *fighting Cocks.*—Now cultivated under the name of *Rib-graſs.* June and july.

Sanguiſorba officinalis. *Great Burnet.* June and july. Moiſt calcareous paſtures.—A coarſe plant. For common Burnet ſee *Poterium Sanguiſorba.*

Alchemilla vulgaris. *Common Ladies Mantle.* June and july. High Paſtures.

Digitized by Google

Primula veris. *Cowſlips*, *Paigles* or *Pagils*. April.
Lyſimachia Nummularia. *Creeping Looſeſtrife*, *Money-wort*, or *Herb Twopence*. June and july. Moiſt meadows.
Campanula rotundifolia. *Round-leaved Bell-flower*. Auguſt and ſeptember. Dry paſtures and heaths.
Campanula glomerata. *Cluſtered Bell-flower*, *leſſer*.
Theſium linophyllum. *Baſtard Toad-flax*. July. In high chalky paſtures.
Bunium Bulbocaſtanum et flexuoſum. *Great* and *common Earth-nut* (corruptly *Yer-nut*) *Kipper-nut* or *Pig-nut*. May and june.
Peucedanum Silaus. *Meadow Sulphur-wort* or *Saxifrage*. Moiſt meadows. Auguſt.
Chærophyllum ſylveſtre. *Smooth Cow-parſley* or *Wild Chervill*, *Orchard-weed* or *Cicely*. April and may. Hedges abundantly, and frequently in the body of the paſture.
Pimpinella Saxifraga. *Common Burnet-Saxifrage*. July and auguſt.
Linum perenne, *Perennial Blue Flax*. June and july. Chalky paſtures.
Galanthus nivalis. February. *Snowdrop*. Meadows, orchards, and hedges.
Narciſſus Pſeudonarciſſus. *Common Daffodil*. March. Orchards and among buſhes.
Allium vineale. *Crow Garlick*. July. Dry paſtures. It gives milk and butter an inſufferable ſtrong taſte.
Allium urſinum. *Broad-leaved Garlick* or *Ramſons*. May and june. Moiſt Meadows and thickets.
Scilla nutans, or Hyacinthus non ſcriptus. *Wild Hyacinth* or *Hare-bell*. May. Hedges, thickets, paſtures.
Juncus glaucus. *Hard Ruſh*, or *Wire Ruſh*. July.
Juncus conglomeratus. *Common Ruſh*. July.
Juncus effuſus. *Soft Ruſh*.
Juncus ſquarroſus. *Moſs Ruſh* or *Gooſe Corn*. June and july. Barren ſandy heaths.
Juncus articulatus. *Jointed Ruſh*. June. Wet meadows.
Juncus uliginoſus. *Little Bulbous Ruſh*. June and july. Wet ſandy and boggy heaths.
Juncus campeſtris. *Hairy Field Ruſh*. April and may. Dry barren paſtures.—Ruſhes are called *Seaves* in Yorkſhire.
Rumex criſpus. *Curled Dock*. June and july.
Rumex acutus. *Sharp Dock*. July.
Rumex obtuſifolius. *Broad-leaved Dock*. July and auguſt.
Rumex Acetoſa. *Common Sorrel*, *Sour Docken*, or *Green Sauce*. June.
Rumex Acetoſella. *Sheep's Sorrel*. June and july. Barren paſtures.
Colchicum autumnale. *Meadow Saffron*. September.
Erica vulgaris. *Common Heath* or *Ling*. June and july.
Erica cinerea. *Fine-leaved Heath*. July and auguſt.
Polygonum Biſtorta. *Great Biſtort* or *Snakeweed*.
Saxifraga granulata. *White Saxifrage* or *Sengreen*. May. Dry paſtures.

From a want of ſufficient diſtinction in Engliſh names, much confuſion has ariſen between Meadow Saxifrage (Peucedanum Silaus), Burnet Saxifrage (Pimpinella Saxifraga), Burnet (Poterium Sanguiſorba), and this White Saxifrage.

Silene inflata. *Bladder Campion*. July.
Stellaria graminea. *Leſſer Stichwort*. May.
Lychnis Flos cuculi. *Meadow Lychnis* or *Ragged Robin*. June. Wet Meadows.
Ceraſtium viſcoſum. *Narrow-leaved Mouſe-ear Chickweed*. May to ſeptember.
Agrimonia Eupatoria. *Common Agrimony*. June and july.
Spiræa Filipendula. *Common Dropwort*. July. In a calcareous or gravelly ſoil. Hogs are fond of the roots.
Spiræa Ulmaria. *Meadow-ſweet*, or *Queen of the Meadows*. June and july. Wet meadows.
Fragaria ſterilis. *Barren Strawberry*. March and april. Dry paſtures.
Potentilla anſerina. *Silver Weed*, *Wild Tanſey*, or *Gooſe Tanſey*. June and july. Wet meadows.

Potentilla repans. *Common creeping Cinquefoil*.
Tormentilla officinalis, *Common Tormentil* or *Septfoil*. June and july. Barren paſtures and heaths.
Ciſtus Helianthemum. *Common dwarf Ciſtus*. July and auguſt. Calcareous or gravelly high paſtures.
Anemone Pulſatilla. *Paſque-flower*. April and may. High calcareous paſtures.
Thalictrum flavum. *Common Meadow-Rue*. July. Moiſt meadows.
Ranunculus Ficaria. *Pilewort*, *Figwort*, or *leſſer Celandine*. April.
Ranunculus bulboſus. *Bulbous Crowfoot*.
Ranunculus repens. *Creeping Crowfoot*.
Ranunculus acris. *Upright Meadow Crowfoot*.

Theſe three plants fill good meadows with their flowers in the months of may, june and july. They are generally known and confounded under the names of *King-cup*, *Gold-knobs*, *Butter-cups*, *Butter-flowers*, *Crowfoot* and *Crowflower*. In Yorkſhire *Gowlans*. They are of a hot and acrid nature, eſpecially the laſt, and are not eaten in a green ſtate by cattle. The notion of their giving butter a yellow tincture, is a vulgar error.

Caltha paluſtris. *Marſh-Marigold*. May. Marſhy paſtures.
Ajuga reptans. *Common Bugle*. May. Moiſt paſtures.
Lamium album. *White Archangel* or *Dead-nettle*. May through the ſummer.
Prunella vulgaris. *Self-heal*, *Hook-heal*, *Sicklewort*, *Carpenter's Herb*. It is a notion, but without foundation, that this herb is good to heal fleſh wounds. The ſame error obtains reſpecting Bugle, Stachys paluſtris, and other plants of this order.
Pedicularis paluſtris. *Marſh Louſewort*. June and july. Marſhy meadows.
Pedicularis ſylvatica. *Paſture Louſewort*. June and july.
Antirrhinum Linaria. *Common Yellow Toadflax*. June and july.
Cardamine pratenſis. *Common Ladies-ſmock*, or *Cuckow-flower*. April and may. Wet meadows.
Geranium pratenſe. *Crowfoot Craneſbill*. June and july. Wet meadows.
Polygala vulgaris. *Milkwort*. June and july. Dry paſtures.
Spartium ſcoparium. *Common Broom*. May and june. Sandy paſtures.
Geniſta tinctoria. *Dyer's Green-weed*, *Woodwaxen*, *Woodweſh* or *Yellows*. July and auguſt. Dry paſtures.
Geniſta piloſa. *Hairy Green-weed*. May. Heaths and high ſandy paſtures.
Geniſta anglica. *Needle furze* or *Green-weed*, *Petty Whin*. May and june. Wet ſpongy heaths.
Ulex europæus. *Common Furze*, *Whin* or *Gorſe*. May through the reſt of the year. Sandy heaths.
Ononis arvenſis. *Reſt-harrow*, *Reſt-plough*, *Cammock*, *Hen Gorſe*, *Ruſt-burn*, (that is *Reſt-bourn*.) June to auguſt. Barren paſtures.
Anthyllis Vulneraria. *Kidney-Vetch*, *Ladies-Finger*. June to auguſt. Chalky and ſandy paſtures.
Lathyrus pratenſis. *Yellow Lathyrus*, or *Meadow Vetchling*. July and auguſt.
Vicia Cracca. *Tufted Vetch*. July and auguſt.
Hippocrepis comoſa *Tufted Horſe-ſhoe Vetch*. May to auguſt. Chalky paſtures.
Hedyſarum Onobrychis. *Saint-foin*. June and july. Chalky hilly paſtures; in which this moſt uſeful plant is not uncommon.
Aſtragalus hypoglottis. *Purple mountain Milk Vetch*. June and july. High chalky and ſandy paſtures.
Trifolium ochroleucum. *Sulphur-coloured Trefoil*. June and july. Dry chalky and gravelly paſtures.
Trifolium fragiferum. *Strawberry-headed Trefoil*. July and auguſt. Moiſt paſtures.
Lotus corniculatus. *Common Bird's-foot Trefoil*, *Cheeſe-cake Graſs*, Yorkſhire. June to auguſt. Common in paſtures and on heaths.

There is a great variety of theſe leguminous plants in moſt paſtures, upon which cattle feed willingly. Moſt of the above, far from being noxious, form a wholeſome mixture with graſs for the food both of kine and ſheep: they cannot therefore be conſidered properly as weeds, unleſs they predominate over the graſ

Digitized by Google

graſs above meaſure. Among ſome of them, as the Clovers, Saintfoin, and Lucerne, which are commonly ſown under the name of Artificial Graſſes, the Graſſes properly ſo called would be conſidered as weeds.

Leontodon Taraxacum. *Common Dandelion.* April to july.

Hedypnois hiſpida, or Leontodon hiſpidum. *Rough Dandelion.* In july. Chiefly in calcareous paſtures.

Hedypnois autumnalis, or Leontodon autumnale. *Autumnal* or *Dandelion Hawkweed.*

Hieracium Piloſella. *Mouſe-ear Hawkweed* or *Yellow Devil's-bit.* May to auguſt. Very common in dry paſtures.

Hypochæris radicata. *Long-rooted Hawkweed.* June to auguſt. Common.

Some of the above Syngeneſious plants are confounded in many places under the name of *Golds* or *Gowls*, from their bright golden-coloured flowers. In Norfolk, according to Mr. Marſhall, they are called *Dindles*, which may perhaps be a corruption of Dandelion.

Cichorium Intybus. *Wild Succory.* Common, chiefly by way-ſides, among graſs. July and auguſt. An improved variety is lately much cultivated, under the name *Chicory*, from the French.

Carduus heterophyllus. *Melancholy Thiſtle.* Moiſtiſh high paſtures. July and auguſt.

Carduus pratenſis. *Meadow Thiſtle.* June.

Carduus acaulis. *Dwarf Thiſtle*, or *ſmall purple Carline Thiſtle.* July and auguſt. Chiefly in a gravelly or calcareous ſoil. It ſpreads, cloſe to the ground, occupies much room, and pricks the mouths of the ſheep.

Gnaphalium dioicum. *Mountain Cudweed.* June and july. High dry paſtures.

Tuſſilago Farfara. *Colt's-foot*, *Fole-foot*, *Horſe-hoof*, or *Bull-foot.* Called *Clote* in Norfolk, according to Mr. Marſhall. March and april. In a wet calcareous ſoil.

Tuſſilago Petaſites. *Common Butter-bur*, or *Peſtilent-wort.* April. Moiſt meadows.

Senecio Jacobæa. *Common Ragwort*, *Ragweed*, *Staggerwort*, *Stanerwort*, *St. James's-wort*, *Seggrum* or *Seagrum:* in Norfolk *Canker-weed*, according to Mr. Marſhall. Nothing eats this large ſtrong weed, which is common in good paſtures. It flowers in july, before which it ſhould be pulled up by hand after rain.

Inula Helenium. *Elecampane.* July and auguſt. Not common.

Inula dyſenterica. *Common Fleabane.* Auguſt. In moiſt places.

Inula pulicaria. *Small Fleabane.* Meadows and ſandy heaths that are wet in winter. September.

Bellis perennis. *Common Daiſy*, in Yorkſhire *Bairnworts.* It flowers during the greater part of the year. No cattle ſeem to eat this plant, which occupies ſo large a ſhare of our paſtures.

Chryſanthemum Leucanthemum. *Great Daiſy*, *Ox-eye* or *Maudlin-wort.* May and june.

Anthemis nobilis. *Sweet Chamomile.* On dry heaths.

Achillea Millefolium. *Common Yarrow* or *Milfoil.* June to auguſt. A large creeping weed, lately recommended for cultivation.

Centaurea nigra. *Common*, *black*, or *leſſer Knapweed*, or *Knobweed*, *Matfellon*, *black Matfellon*, *Cockheads*, or *Bulweed.* June to auguſt. A hard pernicious weed, but too common.

Orchis pyramidalis. *Pyramidal Orchis.* July. Dry paſtures, eſpecially in chalk.

Orchis Morio. *Meadow Orchis.* May and june. Moiſt paſtures.

Orchis maſcula. *Early purple Orchis.* April and may.

Orchis latifolia. *Marſh Orchis.* May and june. Wet meadows.

Orchis maculata. *Spotted Palmate Orchis.* June and july.

Satyrium viride. *Frog Satyrion.* June and july.

Ophrys ovata. *Common Twayblade.* Chiefly among buſhes. June.

Ophrys ſpiralis. *Ladies Traces.* Auguſt and ſeptember Chalk and gravel.

Other ſpecies of this ſingular and elegant tribe of plants are found among graſs, as Fly, Bee, and Spider Ophrys or Orchis, &c. But they are ſcarcely common enough to be reputed weeds.

Carex muricata. *Great Prickly Carex.* *Sedge* or *Segs* is the general name for theſe plants.

Carex palleſcens. *Pale Carex.*

Carex præcox. *Vernal Carex.* Dry paſtures.

Carex pilulifera. *Round-headed Carex.* Heaths.

Carex paniçea. *Pink-leaved Carex.* Moiſt paſtures.

Carex acuta. *Slender-ſpiked Carex.* Wet meadows.

Carex hirta. *Hairy Carex.* Wet meadows. *Share-graſs.* Marſhall.

The ſpecies of Carex are very numerous, and grow chiefly in fens and marſhes; the above however and ſome others abound in the fen paſtures and wet meadows. They are much harſher than the Graſſes, with which they are mowed to fodder cows in winter. Deſtroyed by draining.

Urtica dioica. *Great Stinging Nettle.* Sometimes creeps out of hedges into the body of the paſtures.

Poterium Sanguiſorba. *Common Burnet.* July. High calcareous paſtures. Cultivated.

Ophioglooſſum vulgatum. *Common Adder's tongue.* May. Wet meadows.

Pteris aquilina. *Common Female Fern* or *Brakes.* Dry ſandy land. Spreading its roots deep and wide.

Moſſes of various ſorts, on old paſtures. Theſe may be checked by draining, and by being well dreſſed with coal aſhes, &c. If they cannot thus be reclaimed, they muſt be ploughed up, and kept under tillage for ſome years.

By the above liſt it appears, that by far the greater number of annual weeds infeſt arable lands, and that in graſs the perennials chiefly flouriſh. The reaſon is obvious: in the former, the roots of perennials are continually diſturbed and cut up by ploughing and other operations of agriculture; and the ſeeds of annuals find a ready entrance into land, where the parts are conſtantly undergoing a ſeparation: in the latter, the perennials are often made to ſpread by cutting or eating down the ſtems; and the ſeeds of annuals are not eaſily received into the cloſely compacted turf.

Mr. Marſhall has ſome Weeds which are not in the above liſts.

Corn Weeds.

Artemiſia vulgaris. *Mugwort.* Auguſt. Hedges.

Urtica dioica. *Great ſtinging Nettle.* Placed above among Paſture weeds.

Rumex obtuſifolius. *Broad-leaved Dock.* This alſo is among the Paſture weeds.

Polygonum Perſicaria. *Spotted Arſmart.* July and auguſt. Common in ditches and marſhes.—Polygonum lapathifolium, or *pale-flowered Arſmart*, called alſo *Smart-weed* and *Willow-weed*, is common on dunghills.—Polygonum Hydropiper or *biting Arſmart*, is frequent in ditches.

Ranunculus repens. *Creeping Crowfoot.* Among Paſture weeds.

Achillea Millefolium. *Common Yarrow* or *Milfoil.* Among Paſture weeds.

Agroſtis vulgaris. *Fine Bent-graſs.*

Holcus avenaceus or Avena elatior. *Tall Oat-graſs.*

Daucus carota. *Wild Carrot.* Among Paſture weeds.

Heracleum Sphondylium. *Cow Parſnep.* The ſame.

Carduus acanthoides. *Curled* or *welted Thiſtle.*

Antirrhinum Linaria. *Yellow Toadflax.* See Paſture weeds.

Euphraſia or Bartſia Odontites. *Red eye-bright.* See the ſame.

Prunella vulgaris. *Self-heal.* The ſame.

Galium verum. *Yellow Bedſtraw.* The ſame.

Galium Mollugo. *Great Hedge-Bedſtraw.* Hedges.

Malva rotundifolia. *Dwarf Mallow.*

Vicia Cracca. *Tufted Vetch.* See Paſture weeds.

Convolvulus ſepium. *Great* or *hedge Bindweed.*

Conium maculatum. *Hemlock.* Hedges.

Ballota nigra. *Stinking Horehound.* Hedges.

Eryſimum Alliaria. *Garlick-Creſs*, *Jack by the hedge*, or *Sauce alone.*

Arundo phragmites. *Common Reed.*

Digitized by Google

Paſture Weeds.

Betonica officinalis. *Wood Betony.* Among buſhes.
Aira cæſpitoſa. *Turfy Hair-graſs*, or *Haſſock-Graſs.* In Yorkſhire *Bull's-forehead.*
Cineraria paluſtris. *Marſh Fleabane.* Ditches and marſhes.
Achillea Ptarmica. *Sneeze-wort* or *Gooſe-tongue.* Chiefly in hedges and among buſhes.
Equiſetum paluſtre. *Marſh Horſe-tail*, or *Joint-graſs.*
Angelica ſylveſtris. *Wild* or *water Angelica.* Watery places and by rivulets.
Myoſotis ſcorpioides. *Mouſe-ear Scorpion-graſs.* See Arable weeds.
Carduus arvenſis. *Common Thiſtle.* See Arable weeds.
Carduus lanceolatus. *Spear Thiſtle.* See the ſame.

Buſhes or Shrubs in Paſtures.

Cratægus Oxyacantha. *Hawthorn* or *White-thorn.*
Prunus ſpinoſa. *Sloe* or *Black-thorn.*
Roſa arvenſis. *Field Briar.*
Rubus fruticoſus. *Common Bramble.*
Ulex europæus. *Furze, Whins* or *Gorſe.*
Ononis arvenſis. *Reſt-harrow, Hen-gorſe* or *fin.*
Geniſta tinctoria. *Dyer's-weed*, or *Yellows.*

Moſt of the above are found in hedges or among buſhes, but occaſionally ſteal into the field or paſture. More of the ſame ſort might have been added; but perhaps ſome readers may think there are already too many.

Fitzherbert, the father of Engliſh Huſbandry, mentions the following Weeds:
Thiſtles.
Kedlocks. *Sinapis arvenſis.*
Dockes.
Cockle.
Drake.
Darnolde; Darnell. *Lolium temulentum.*
Gouldes. *Chryſanthemum ſegetum.*
Haudoddes.
Dogfenell.
Mathes. See *Anthemis Cotula.*
Ter or Terre. Fumitory or Fumiterry. *Fumus terræ. Fumaria.*
Dee Nettyls. *Lamium album.*
Dodder. *Cuſcuta.*

Weeds mentioned by Tuſſer.

Mayweed.
Thiſtle.
Fitch, Vetch or Tare.
Brake. *Pteris aquilina.*
Cockle.
Boddle. See *Chryſanthemum ſegetum* and *Centaurea Cyanus.*
Muſtard.
Hemlock.
Burr.
Tine or Tine Tare.
Mallow.
Nettle.
Titters or Tine.

Weeds mentioned by Tull.

Crow-needles. *Scandix Peſten-Veneris.*
Red-weed.
Echium.
Couch-graſs.
Colt's-foot.
Melilot.
Fern.
Charlock.

For the deſcriptions of weeds, and the methods of extirpating the moſt noxious, ſee the ſeveral articles in the courſe of this work.

There are two ways of extirpating weeds from arable lands: by fallowing and by weeding.

By fallowing is meant repeated ploughings, harrowings, &c. between the crops. The continuance of a fallow, and the number of ploughings requiſite, depend on the ſeaſon, and on the number and nature of the weeds to be deſtroyed. If the ſpring ſeaſon be found inſufficient, take the ſummer, and even the autumn, the winter, and the enſuing ſpring, rather than crop an under-worked fallow. One ſtirring towards the cloſe is frequently more valuable than two or three ploughings at the outſet. To begin a fallow without continuing it until its intention be fully accompliſhed, is throwing away labour unprofitably.

By weeding is meant deſtroying or checking weeds whilſt the crop is growing; whether the operation be performed with the hoe, the ſpadle or ſpud, the hook, or the hand. Next to the plough and harrow, the hoe is the moſt deſtructive to ſeed weeds; but the hand ought to give the finiſh to weeding: the later this is done, provided the crop be not materially injured by treading, the greater will be its effect. The cloſe of this operation is ſimilar to that of the fallow. One additional weeding is given at a ſmall expenſe; and without it perhaps, thoſe which preceded were of little benefit. One weed left to ſpread its ſeeds this year may be the cauſe of an hundred the next.

The common perennial Way-Thiſtle or Corn Thiſtle, increaſes almoſt without bounds both by ſeeds and roots. Neither fallowing alone, nor weeding alone, will prevent its miſchief: their joint efforts are neceſſary to keep it within bounds: to work its total extirpation from a ſoil it affects, is ſcarcely poſſible. See *Serratula arvenſis.*

Obſerve of this and other ſucculent weeds, that when the ſeeds are impregnated, they will ripen after the plants are cut down or torn up by the roots; they ſhould therefore either be cut down as ſoon as they begin to flower, or elſe be raked into heaps and burnt.

Quich-graſs increaſes in arable lands entirely by roots, which in a looſe ſoil will diffuſe themſelves to an unlimited diſtance. Every joint requires only air and openneſs of ſoil to fit it for vegetation. To deſtroy it, break up the ſoil, ſo as to give it the greateſt ſurface. Then endeavour to deſtroy the young ſuckers whilſt they are yet in a delicate tender ſtate, before they have had time to eſtabliſh themſelves, or to ſend out freſh roots. In deſtroying the firſt crop of ſuckers, a ſecond expoſure of roots takes place, and to render the expoſure as ample as poſſible, the greateſt quantity of ſurface ſhould ſtill be preſerved. Hence it follows that the plough is the fitteſt implement for the deſtruction of Quich.

The common practice of harrowing out live roots, and burning them or carrying them off, is a waſte of labour, and an impoveriſhment of the ſoil.

To attempt to deſtroy it with the hoe, or any other implement of weeding, implies ignorance or folly in the extreme. See *Triticum repens.*

Docks. See *Rumex.*

Cleavers, Gooſe-graſs, or Hairough. *Galium Aparine*, is in ſome diſtricts conſidered as one of the worſt weeds which wheat can be infeſted with; the ſeeds being very difficult to ſeparate from wheat, and when ground with it, being hurtful to the flour.

This is an annual plant, with a very feeble root, and may eaſily be deſtroyed. When it is thick on the ground, and by climbing has gained the aſcendency of the corn, it may be dragged out with iron-toothed rakes with good effect and quick diſpatch. In vacancies, and whilſt the corn is low, a ſmall hoe may be uſed; but in general it is beſt to draw it with the hand. The ſeeds lie long in the ſoil without loſing their vegetative quality.

Spear Thiſtle and other biennial weeds may be deſtroyed with the ſpadle or ſpud, and with the ſmall hoe, taking off the crown of the root within the ſurface of the ground. See *Carduus lanceolatus.*

Creeping Crowfoot, Creeping Bent-graſs, Silverweed, and other perennial creeping weeds, form a claſs of troubleſome enemies to corn land. The firſt and laſt ſend out runners like the ſtrawberry: the ſecond ſends out rootlets from the joints of the ſtem, which being feeble, falls to the ground as its length is extended and the weight of its top is increaſed. The parent roots are fibrous and eaſily deſtroyed.

If theſe weeds are taken in time, they are readily extirpated by weeding, but when once they have bound themſelves to the ſurface with innumerable ligatures, fallowing is the only means of deſtruction. The harrow may be uſed in the firſt ſtages of the fallow, provided

Digitized by Google

vided no other root-weeds are to be at the ſame time deſtroyed. Skimming the ſurface with the plough, ſhim, horſe-hoe, or paring-ſpade, is more effectual againſt theſe weeds than deep ploughing [r].

WEIGELIA. (*So named by Thunberg in honour of Chriſt. Ehrenfr. Weigel, author of* Flora Pomerano-Rugica, &c. Berol. 1769. 8°.)

Lin. gen. Schreb. n. 280. *Thunb. nov. gen.* 5. *fl. jap.* 6. *Juſſ.* 421.

Claſſ. 5. 1. Pentandria Monogynia.

GENERIC CHARACTER.

CAL. *Perianth* five-leaved: *ſegments* awl-ſhaped, erect, equal.

COR. one-petalled, funnel-formed: *tube* villoſe internally, length of the calyx: *border* bell-ſhaped, half-five-cleft: *ſegments* ovate, obtuſe, from erect ſpreading.

STAM. *Filaments* five, inſerted into the tube, filiform, erect, almoſt the length of the corolla. *Anthers* erect, linear, bifid at the baſe, obtuſe at the tip.

PIST. *Germ* four-cornered, truncate, ſmooth, ſuperior. *Style* from the baſe of the germ, filiform, a little longer than the corolla. *Stigma* peltate, flat.

PER.

SEED naked?

ESSENTIAL CHARACTER.

Cal. five-leaved. *Cor.* funnel-form. *Style* from the baſe of the germ. *Stigma* peltate. *Seed* one.

SPECIES.

1. Weigelia japonica.
   Lin. ſpec. ed. Willd. 1. 836. *Thunb. jap.* 90. *t.* 16. *act. holm.* 137. *t.* 5. *Linn. tranſ.* 2. 331.
   Sima utſugi et Nippon utſugi. *Kæmpf. amoen.* 5. 855.
   Leaves ſeſſile ovate-lanceolate.
2. Weigelia coreœenſis.

2. Weinmannia hirta.
   Lin. ſpec. ed. Willd. 2. 437. *Swartz prodr.* 63. *deſcr.* 2. 691. *Brown. jam.* 212.

[r] Marſhall, Yorkſhire, 1. 361—376. [s] Thunberg.

Leaves pinnate, leaflets ovate ſerrate-crenate, beneath and on the racemes hirſute.

3. Weinmannia tomentoſa
   Lin. ſyſt. 376. *Willd.* 2. 437. *ſuppl.* 227.
   Leaves pinnate, leaflets ovate quite entire tomentoſe underneath, ſtipules caducous.
4. Weinmannia trifoliata.
   Lin. ſyſt. 376. *Willd.* 2. 438. *ſuppl.* 227. *Lamarck illuſtr. gen. t.* 313. *f.* 2. *Thunb. prodr.* 77.
   Leaves ternate, leaflets elliptic-lanceolate ſerrate very ſmooth, panicles compound.
5. Weinmannia racemoſa.
   Lin. ſyſt. 376. *Willd.* 2. 438. *ſuppl.* 227. *Forſt. prodr. n.* 173.
   Leaves ſimple obovate-elliptic obtuſe toothed, racemes ſmooth.
6. Weinmannia parviflora.
   Lin. ſpec. ed. Willd. 2. 438. *Forſt. prodr. n.* 174.
   Leaves ſimple oblong acuminate toothed, racemes rough-haired terminating panicled.

DESCRIPTIONS, &c.

1. This is a ſmall tree with oppoſite branches, the laſt of which are ſubpubeſcent. Leaves oppoſite, unequally pinnate; the common petiole winged, with ſubovate joints: leaflets eleven or thirteen, ſmall, naked, blunt, oppoſite, ſeſſile, narrower on the inner ſide towards the baſe, having three or four ſerratures on each ſide. Stipules ovate, the ſize of the leaves, deciduous, ſolitary between the pairs of the petioles. Racemes terminating, ſolitary, peduncled, longer than the leaves, erect, ſimple. Flowers numerous, white, the ſame ſize as Tiniarella. Pedicels one-flowered, ſeveral from each point of the peduncle. Calyx-leaves oblong, white. Petals lanceolate three times as long as the calyx. Germ ovate, two-grooved. Styles white, filiform. Stigmas headed [t].—Swartz remarks, that it varies from the ſtature of a ſhrub to that of a tree forty feet in height. Native of Jamaica. Browne's plant is not this, but the next ſpecies.

2. This differs from the preceding in the pubeſcence of moſt of the parts; in having the joints of the common petiole ſubcordate, not obovate; the capſules oblong and ſhort, not roundiſh, and longer beaked [u]. Native of Jamaica, on the top of the blue mountains in the ſouthern parts of the iſland; alſo in Montſerrat. Browne ſays it riſes by a weakly ſlender ſtem, and ſhoots frequently to the height of ſix or ſeven feet; that the branches are few, ſlender, and oppoſite, as well as the ribs, which are always beautifully winged between the leaves, and that the flowers riſe in looſe bunches at the extremities of the branches.

3. This is a very branching leafy tree with a browniſh bark. Leaves oppoſite, unequally pinnate. Common petiole winged, with obovate joints. Leaflets eleven or thirteen, ſmall, thickiſh, regular, very downy beneath. Stipules one on each ſide, bigger than the leaflets, deciduous. Racemes towards the top very cloſe, like ſpikes, on very ſhort pedicels. Nectary bell-ſhaped, ſurrounding the ſtamens, quite entire, membranaceous. Found in New Granada by Mutis.

4. A very ſmooth ſhrub, not differing much in appearance from the Pteleas. Leaves oppoſite. Panicles axillary. Native of the Cape of Good Hope [x].

5. Branches and branchlets ſmooth. Leaves oppoſite, petioled, ſmooth on both ſides, bluntly toothed as in Populus monilifera. Racemes very long, axillary, ſolitary or in pairs, terminating. Native of New Zealand.

6. Branches round, ſmooth; branchlets pubeſcent. Leaves oppoſite, on ſhort petioles, ſmooth on both ſides, with remote ſharp teeth. Racemes three to ſix at the ends of the branches in panicles. It differs from the preceding in the form of the leaves, the pubeſcence of the racemes and branchlets, and in having the flowers four times ſmaller. Native of the iſland of Otaheite [y].

WESTRINGIA. *(So named by J. E. Smith, M. D. in honour of John Peter Weſtring, author of a Diſſertation on the Lichen tribe, and their uſes in dyeing, printed in the Tranſactions of the Stockholm Academy for* 1794*).*
Smith monogr. in Tracts of Nat. Hiſt. 1798.
Claſſ. 14. 1. Didynamia Gymnoſpermia.
Nat. Order of *Verticillatæ. Labiatæ* Juſſ.

GENERIC CHARACTER.

Cal. one-leafed, permanent, tubular bell-ſhaped, with five ſides, and five prominent angles, without furrows or ſtreaks, divided about half way into five equal, erect, lanceolate, beardleſs ſegments.

Cor. one-petalled, ringent, twice as long as the calyx, reverſed: *tube* length of the calyx, with a hairy orifice: *border* four-lobed: *upper-lip* a little longer, erect, cloven half way down: *lower-lip* in three deep equal ſegments, divaricating, and of a linear oblong form.

Stam. *Filaments* four, about half as long as the border, ſpreading: two lower ſhorter, and moſt frequently abortive. *Anthers* roundiſh, two-lobed, incumbent.

Pist. *Germ* four-lobed. *Style* filiform, length of the ſtamens. *Stigma* cloven, ſmall.

Per. none.

Seeds four, naked, obovate.

ESSENTIAL CHARACTER.

Cal. half-five-cleft, five-ſided. *Cor.* reverſed, with four ſegments, the longeſt erect, cloven. *Stam.* diſtant; the two ſhorter or loweſt abortive.

SPECIES.

Smith monogr. 282. *t.* 3.
Cunila fruticoſa. *Solandri. Willd. ſpec.* 1. 122.
C. fruteſcens. *Donn cat. cant.* 5.

DESCRIPTION, &c.

This is a ſhrub very much branched: the branches either oppoſite or four together, ſquare, ſilky, leafy. Leaves in fours, on very ſhort ſilky footſtalks, ſpreading, linear-lanceolate, entire, revolute, rather pointed; of a bright ſhining green above, and almoſt naked; clothed with white ſilky down beneath. Stipules none. Flowers from the upper part of the branches, axillary, ſolitary, on ſhort flower-ſtalks. At the baſe of the calyx a pair of linear ſhort ſilky bractes. Calyx ſilky, its ſegments naked with revolute margins. Corolla white, with purple ſpots about the orifice.

The leaves are ſlightly bitter, not aromatic; the flowers not inelegant, but without ſmell.

Native of New South Wales, near Port Jackſon, and has flowered ſeveral times in the Engliſh Greenhouſes *.

DESCRIPTIONS, *&c.*

1. This is a tree ſeven or eight feet in height, and ſeven or eight inches in diameter, with a gray bark and a white looſe wood; it ſpreads at top into many ſtraight, knotted branches. Leaves oppoſite, ovate, oblong, ſmooth, quite entire, waved, on ſhort half-embracing petioles. Flowers in a ſubſeſſile corymb of three or four flowers, with a little ſcale at the baſe of the peduncle and of each flower. The whole plant abounds in a milky juice. The fruit macerated in water has a pleaſant acid flavour. Native of Cayenne and Guiana, in woods, flowering in ſeptember.

2. This is a ſhrub with many ſpreading knotty branches, ſpreading over neighbouring trees. Leaves ovate-acute, ſmooth, quite entire, waved, oppoſite, on ſhort embracing petioles. Flowers in axillary racemes, appearing in may. It abounds, like the other, in a viſcid milky juice. Native of Guiana [b].

Peduncles axillary heaped one-flowered, flowers four-piſtilled.

DESCRIPTIONS, &c.

1. This is an evergreen tree, higher and larger than an Apple Tree, ſpreading very much both in root and branches. Leaves of a light green, an inch and half long, and an inch broad in the middle, decreaſing to both ends, but terminating bluntly; footſtalks half an inch in length. Flowers axillary, two, three or more together, on peduncles a quarter of an inch long, ſomewhat like thoſe of the Honeyſuckle, five-petalled, milk white, and ſmelling like Jaſmine. Berries two, three, or more, on the ſame common footſtalk, of a light green colour with ſome black ſpots, containing ſeveral black aromatic ſeeds, ſomewhat like the ſtones in grapes.

Captain Winter who went out with Sir Francis Drake, when he went round the world, at his return brought the bark of this tree with him from the ſtraits of Magellan. He had found it to be very helpful to his ſhip's crew, both inſtead of other ſpices with their meat, and as a medicine very powerful againſt the ſcurvy. Cluſius, from the Captain's name, called it *Cortex Winteranus*, and the tree *Magellanica aromatica arbor.* The writer of the journal of the Dutch ſhips that went to the ſtraits of Magellan about 1599, called it *Lauro ſimilis arbor, licet procerior, cortice Piperis modo acri et mordenti.* And Sebald de Weert, who was there, ſays, that both leaves and bark were uſed with their meat and muſcles, to correct them in ſo cold a climate. Caſpar Bauhin called it *Laurifolia Magellanica cortice acri:* and Jonſton, *Arbor laurifolia Magellanica.*

Mr. George Handyſide brought home with him a ſpecimen of the leaves and flowers, and of the ſeed, (whence the figure in the Philoſophical Tranſactions was drawn.) He uſed the leaves, with other herbs, in fomentations, with very good ſucceſs: he alſo gave the bark inwardly, boiling half a dram of it with ſome carminative ſeeds, and giving it to thoſe of his crew who were much afflicted with the ſcurvy. It uſually ſweated them, and they were very much relieved. He likewiſe adminiſtered the ſame medicine to many of the crew who were very ill by eating of the Sea Lion; and they were much relieved by it, although they had loſt moſt of their ſkin, which peeled off in large pieces [c].

John Bauhin ſeems to be the firſt who confounded this bark with that of *Canella alba.* Profeſſor Murray, in the fourteenth edition of Syſtema Vegetabilium, was the firſt who made a diſtinct genus of Canella, and thus corrected the miſtake of Linneus, who had combined the two genera, under the name of *Laurus Winterana*; though he afterwards made the *Canella* a ſeparate genus, under the name of *Winterania* [d].

Forſter named Winter's bark *Drimys*, from the greek δριμυς, on account of its acrid pungent taſte, and it ſtands under this name in the ſupplement of the younger Linneus. But Forſter (in Comm. Gott.) afterwards corrected himſelf, and called it Wintera; and this name has been adopted by Murray and Willdenow. See *Canella alba.*

2. Branches longer than in the preceding. Leaves oblong, beneath more glaucous ſo as to be almoſt white; they are alſo longer. Peduncles one, two or three, filiform, elongated, yet ſhorter than the leaves, trifid above the middle. Pedicels one-flowered. Calyx as in the preceding. Petals as in that, but twelve, more oblong, whence the flowers are larger; the inner petals are ſmaller than the outer ones. Stamens as in the preceding. Germs eight, ſeldom varying from that number. Berries as many as there are piſtils. Seeds about two, ſhining. The flavour of the bark the ſame as in the preceding, of which perhaps it is only a variety owing to the heat of the climate. Found in New Granada by Mutis.

3. The flavour of the whole plant, and eſpecially of the bark, is very acrid and pungent. It flowers in november, and is nearly allied to Michelia. Native of New Zealand [e]. Forſter remarks, that it is ſingular that the younger Linneus ſhould have aſſigned one piſtil only to the flower of this plant.

DESCRIPTION, &c.

Stem two feet high, ancipital, covered with ſheaths of leaves. Leaves enſiform, alternate, approximating, ſtriated, narrow, the upper ones longer than the ſtem, with imbricate ſheaths. Spike compoſed of alternate, imbricate ſpikelets. Spathelets looſe, ſcarioſe, ſubbiflorous, lanceolate. Corolla funnel-form, of the ſame figure with Gladiolus Meriana, the tube or neck altogether black; the border ſix-parted, equal, yellow; the three other ſegments tomentoſe on the outſide. Stamens erect, white. Style with a ſingle very ſlightly trifid ſtigma. Native of the Cape of Good Hope, flowering in may[t].

Root tuberous. Stem ſomewhat woody, ſingle or branched, covered at top with flat leaves ſheathing at the edge, imbricate in a double fan-like row: gems terminating or axillary alſo, ſeſſile ſubbiflorous compreſſed, with ſeven or eight imbricate diſtich ſcales, the two inner ones longer bifid: each flower having a ſhort ſpathe concealed within the inmoſt gem[t].

——— Wild. See *Reſeda*.

WOLF'S-BANE. See *Aconitum*.]

WOODS and groves are the greateſt ornaments to a country ſeat, and every ſeat is greatly defective without them; Wood and water being abſolutely neceſſary to render a place agreeable and pleaſant. Where there are Woods already grown to a large ſize, ſo ſituated as to be taken into the garden or park, or ſo nearly adjoining, as that an eaſy communication may be made from the garden to the Wood; they may be ſo contrived by cutting winding walks through them, as to render them the moſt delightful and pleaſant parts of a ſeat (eſpecially in the heat of ſummer), when thoſe walks afford a goodly ſhade from the ſcorching heat of the ſun.

Where perſons have the convenience of grown Woods near their habitation, ſo as that there may be an eaſy communication from one to the other; there will be little occaſion for wilderneſſes in the garden; ſince the natural Woods may be ſo contrived as to render them much pleaſanter than any new plantation can poſſibly arrive to within the compaſs of twenty years, where the trees make the greateſt progreſs in their growth; and in ſuch places where their growth is ſlow, there cannot be expected ſhade equal to the grown Woods, in double that number of years; but there is not only the pleaſure of enjoying a preſent ſhade from theſe Woods, but alſo a great expenſe ſaved in the planting of wilderneſſes; which, if they are large, and the trees to be purchaſed, will amount to no ſmall ſum. If the Wood is ſo ſituated as that the garden may be contrived between the houſe and that, then the walk into the Wood ſhould be made as near to the houſe as poſſible that there may not be too much open ſpace to walk through in order to get into the ſhade; if the Wood is of ſmall extent, then there will be a neceſſity for twiſting the walks pretty much, ſo as to make as much walking as the compaſs of ground will admit; but there ſhould be care taken not to bring the turns ſo near each other, as that the two walks may be expoſed to each other, for want of a ſufficient thickneſs of Wood between; but where the Wood is large, the twiſts of the walks ſhould not approach nearer to each other than fifty or ſixty feet; in very large Woods, they ſhould be at a greater diſtance; becauſe when the under Wood is cut down, which will be every tenth or twelfth year, according to its growth, then the walks will be quite open, until the under Wood grows up again, unleſs a border of ſhrubs, intermixed with ſome evergreens, is planted by the ſides of the walks, which is what I would recommend, as this will greatly add to the pleaſure of theſe walks.

Theſe Wood walks ſhould not be leſs than eight or nine feet broad in ſmall Woods; but in large ones fifteen feet will not be too much; and on each ſide of the walks the border of ſhrubs and evergreens may be nine or ten feet broad; which may be ſo managed, as to ſhut out the view from one part of the walk to the other, at thoſe times when the under Wood is cut down, at which times there will be an abſolute occaſion for ſuch plantations; and at all times they will afford great pleaſure, by adding to the variety, as alſo by their fragrant odour.

[t] Hort. kew.

[t] Linn. mant. [t] Juſſieu.

The

Digitized by Google

The former method which was practiſed in cutting theſe walks through Woods, was to have them as ſtraight as poſſible, ſo that there was much trouble to make ſights through the Woods, for direction how to cut them; but where this was practiſed, every tree which ſtood in the line, good and bad, was cut down, and many times boggy or bad ground was taken into the walks; ſo that an expenſe of draining and levelling was neceſſary to render them proper for walking on; beſides this, there were many other inconveniencies attending theſe ſtraight cuts through Woods, as, firſt, by letting in a great draught of air, which in windy weather renders the walks unpleaſant; and theſe cuts will alſo appear at a great diſtance from the Woods, which will have a very bad effect; therefore the modern practice of twiſting the walks through Woods, is to be preferred. In the cutting theſe walks, there ſhould be particular care taken to lead them over the ſmootheſt and ſoundeſt part of the ground, as alſo to avoid cutting down the good trees; ſo that whenever theſe ſtand in the way, it will be better to lead the walk on one ſide, than to have the tree ſtand in the middle; for although ſome perſons may contend for the beauty of ſuch trees which are left ſtanding in walks, yet it muſt be allowed, that unleſs the walk is made much broader in thoſe places than in the others, the trees will occaſion obſtructions to the walkers, eſpecially when two or three perſons are walking together, ſo that it will be much better to have the walks entirely clear from trees; and where any large-ſpreading trees ſtand near the walk, to cut away the ſmall Wood, ſo as to make an opening round the trees, where there may be ſome ſeats placed, for perſons to reſt under the ſhade. The turns made in theſe walks ſhould be as eaſy and natural as poſſible; nor ſhould there be too many of them, for that will render the walking through them diſagreeable; therefore the great ſkill in making theſe walks, is to make the turns ſo eaſy as not to appear like a work of art, and yet not to extend them ſtraight to ſo great length, as that perſons who may be walking at a great diſtance, may be expoſed to the ſight of each other; both theſe extremes ſhould be avoided as much as poſſible, ſince they are equally diſagreeable to perſons of true taſte. When a Wood is properly managed in this way, and a few places properly left like an open grove, where there are ſome large trees ſo ſituated as to form them, there can be no greater ornament to a fine ſeat than ſuch a Wood.

We ſhall now treat of the culture of Woods for profit to the poſſeſſor, and for the public benefit of the nation. The great deſtruction of the Woods and foreſts which has been of late years made in this country, ſhould alarm every perſon who wiſhes well to it; ſince there is nothing which ſeems more fatally to threaten a weakening, if not a diſſolution, of the ſtrength of this once famous and flouriſhing nation, than the notorious decay of its timber; and as this devaſtation has ſpread through every part of the country, ſo unleſs ſome expedient be ſeriouſly and ſpeedily reſolved on, to put a ſtop to this deſtruction of the timber, and alſo for the future increaſe of it, one of the moſt glorious bulwarks of this nation will, in a few years, be wanting to it.

And as there are ſmall hopes of this being remedied by thoſe intruſted with the care of the public Woods: therefore, unleſs private perſons can be prevailed on to improve their eſtates, by encouraging the growth of timber, it is greatly to be feared, that in an age there will be a want of it for the ſupply of the navy.

It has been often urged, by perſons whoſe judgment in other affairs might be depended on, that the great plantations, which for ſeveral years paſt, have been carried on in ſeveral parts of this kingdom, will be of public benefit, by the propagation of timber; but in this they are greatly miſtaken; for in moſt of the plantations which have been made for years paſt, there has been little regard had to the propagation of timber; preſent ſhade and ſhelter have been principally conſidered; and in order to obtain theſe ſoon, great numbers of trees have been taken out of Woods, hedge rows, &c. which, if they had remained in their firſt ſituation, might in time have afforded good timber; but by being tranſplanted large, are abſolutely rendered unfit for any uſe but fuel; ſo that the great quantity of plantations which have been made, I fear, will rather prejudice than be of uſe, to the improvement of timber; nor is there any other method of increaſing the uſeful timber of this country, than by ſowing the ſeeds in the places where they are to remain; or in ſuch ſituations, where there are plenty of Oaks in the neighbourhood, if the ground is properly fenced, to keep out cattle and vermin, the Acorns which drop from thoſe trees will ſoon produce plenty of young trees; which, if properly taken care of, will ſoon grow to Woods.

The two moſt ſubſtantial timbers of this country are the Oak and Cheſtnut, though the latter has been of late years almoſt entirely deſtroyed in England, ſo that there are ſcarce any remains of trees of ſize in the Woods at preſent. But as I have already treated largely of the method of propagating both theſe trees for profit, under their reſpective titles, I ſhall not repeat it here. Next to theſe the Elm is eſteemed as a profitable timber; but of theſe there are few cultivated in Woods, eſpecially in the ſouth part of England, where they chiefly grow in hedge rows, or plantations near houſes; but in the north-weſt part of England, there are numbers of very large trees of the Witch-Elm growing in parks, and ſome in Woods, as if that tree was a native of this country, which has been much doubted; though as this tree propagates itſelf by ſeeds, it may be deemed an indigenous plant in England.

The Beech is another tree common in the Woods, eſpecially upon the chalky hills of Buckinghamſhire, Kent, Suſſex, and Hampſhire, where there are ſome very large Woods, entirely of this ſort; ſome of which have been of long ſtanding, as appears by the age of the trees; but whether this tree is a native of this country, has been a point often diſputed.

The Aſh is a very profitable tree, and of quick growth; ſo that in leſs than an age, the trees will arrive to a large ſize from the ſeeds; therefore a perſon may hope to reap the profits of his labour, who ſows the ſeeds; but this is not a beautiful tree to ſtand near a habitation, being late in the ſpring in putting out its leaves, and the firſt that ſheds them in autumn; nor is it a friendly tree to whatever grows near it, the roots drawing away all the nouriſhment of the ground, whereby the trees or plants which grow near are deprived of it; ſo that where the Aſh-tree grows in hedge rows, the hedge rows in a few years are entirely deſtroyed; and if they are in paſture grounds, and the cows browze on them, the butter made with their milk will be bad; for which reaſon the Aſh ſhould be ſown ſeparate in lands which are incloſed, where cattle are not permitted to come, and at a diſtance from the habitation.

Upon ſandy or rocky ſoils the Scotch Pine will thrive exceedingly, and turn to great advantage to the planter, provided the plants are planted young, and treated in the manner directed in the article PINUS, to which the reader is deſired to turn, to avoid repetition. There are alſo ſeveral aquatic trees, which are very profitable to thoſe who have low marſhy lands, where the harder kinds of timber will not thrive; theſe are the Poplars of ſeveral ſorts, the Willow, Alder, &c. but as theſe, and all the other kinds of trees have been fully treated of, both as to their propagation and uſes, and alſo an account of the different ſoils in which each will thrive beſt, under their reſpective titles, the reader is referred to them for farther information; and I ſhall next treat of the general management of Woods, of whatever kinds of trees they are compoſed.

Where there are young Woods, great care muſt be taken of the fences; for if cattle ſhould get in among the trees, eſpecially while they are young, they will in a ſhort time do infinite damage to them, by browzing on the branches, or barking the trees; ſo that during the firſt twenty years of their growth, they ſhould be ſecured from them, and alſo from hares and rabbets, otherwiſe in ſevere froſt, or when the ground is covered with ſnow, whereby they are deprived of other food,

Digitized by Google

they get into the Woods, and eat off the bark from the young trees, and gnaw all the branches within their reach; ſo that in a few days, where there are plenty of theſe animals, there may be ſuch deſtruction made among the young trees, as cannot be retrieved, but by cutting them down to the ground, which will be a loſs of ſeveral years: therefore thoſe perſons who have the care of young Woods, ſhould be very diligent in froſty weather, in looking over the trees, and ſtopping the holes in the fences, to keep out all vermin.

Another care to be taken of young Woods, is the thinning the trees from time to time, as they increaſe in their growth; but in doing this, there muſt be great caution uſed; for it ſhould be gradually performed ſo as not to open the trees too much, to let in the cold air among them, which will greatly retard their growth; nor ſhould the trees be left ſo cloſe, as to draw each other up like May-poles, but rather obſerve a medium in this work, cutting down a few each year according as there may be neceſſity for it, being careful not to permit thoſe to ſtand, which may ſpoil the growth of the neighbouring trees, always obſerving to leave thoſe trees which are the moſt promiſing.

The young trees in theſe Woods ſhould not be lopped or pruned, for the more they are cut, the leſs they will increaſe in bulk; every branch which is cut off, will rob the tree of its nouriſhment, in proportion to the ſize of the branch; therefore the hatchet ſhould not be ſuffered to come into young Woods, unleſs in the hands of ſkilful perſons.

Where perſons have more regard to the future welfare of the timber than their immediate profit, the under Wood ſhould be grubbed up as the trees advance, that the roots may have the whole benefit of the ſoil, and their ſtems enjoy the free air; without which, their ſtems are generally covered with Moſs, and their growth greatly ſtinted; as may be obſerved in all ſuch Woods, where there is any quantity of underwood remaining; in which places it is rarely found, that the trees do ever grow to a large ſize; therefore where large timber is deſired, the trees muſt have room to extend their roots and branches, without which it cannot be expected; but from a covetous temper, many people let their underwood remain as long as it will live; for as the timber increaſes, the underwood will be gradually decaying, by the ſhade and drip of the large trees; ſo that by this method the timber ſuffers more in a few years, than the value of the underwood; therefore by endeavouring to have both, neither of them can be ſo good, as where they are ſeparately preſerved.

If perſons who have eſtates would be careful to nurſe up trees in their hedge rows, it would in time become a fortune to their ſucceſſors, as hereby the timber growing in the hedges may be worth more than the freehold of the eſtate, which has often been the caſe with eſtates from which their poſſeſſors have cut down timber for fortunes for their younger children; the frequency of this ſhould encourage perſons to be a little more attentive to the growth and preſervation of young Woods, ſince the expence and trouble is not great, and the future profit very certain; beſides, the pleaſure of ſeeing trees of a man's own ſowing make yearly advances, muſt be very great to thoſe who have any reliſh for country amuſements.

There are ſeveral perſons who plant copſes for cutting every ten or twelve years, according to their growth. Theſe are uſually planted in autumn, either with ſtools or young plants, which are drawn out of the Woods; the latter ſhould always be preferred to the former. Theſe copſes are commonly planted with ſeveral ſorts of trees, as Oak, Beech, Cheſtnut, Aſh, Birch, Willow, &c. but the Aſh and Cheſtnut are the moſt profitable, where they grow kindly, becauſe the poles are very valuable; theſe alſo are good for hoops, ſo that there is no danger of having ſale for theſe copſe Woods when they are fit for cutting; but where the copſes are intended to remain, there ſhould be no ſtandard-trees left for timber; becauſe as the heads of the trees ſpread, and overtop the under Wood, it will cauſe that to decay; and where the ſtandards are left upon the ſtumps of the copſe Wood, they will never grow to a large ſize, nor will the timber be ſo valuable as that produced immediately from a young root; and whoever will make the experiment, will be convinced, that it is more for the advantage of both to keep them in diſtinct Woods.

But where perſons plant copſes upon land free from trees, it will be the better method to ſow the ſeeds, eſpecially if Cheſtnut, Oak or Beech, are the trees intended; for although it is a prevailing opinion with the generality of perſons, that by planting they ſave time, yet I am ſure of the contrary; for if the ſeedling plants are kept clear from weeds, they will in eight or ten years out-grow thoſe which are planted; and theſe unmoved copſes will continue much longer in vigour than the other; ſo that for either timber or copſe Wood, the beſt method is to prepare the ground well, and ſecure the fences, and ſow the ſeeds, which is ſo far from loſing, that in twenty years it will be found to gain time, which is what every planter wiſhes to do.

The uſual time of felling timber is from november to february, at which time the ſap in the trees is hardened; for when the ſap is flowing in the trees, if they are cut down, the worm will take the timber, and cauſe it to decay very ſoon; therefore if the durableneſs of the timber is conſidered, the trees ſhould always be cut in the winter months; but as the bark of the Oak is ſo valuable for tanning leather, there has been a law paſſed, to oblige perſons to cut theſe trees during the ſpring ſeaſon, when the bark will readily peel off; by which the timber is rendered unfit for building either ſhips or houſes, as it will be very ſubject to caſt, rift, or twiſt, and the worm will ſoon take it; therefore it would be more for the public benefit, if a law were enacted to oblige every perſon to ſtrip off the bark of ſuch trees as are deſigned to be cut down in the ſpring, leaving the trees with their branches ſtanding till the following winter, which will be found to anſwer both purpoſes well.

[*Directions for planting Woods by Mr. Boutcher.*

Where the ſoil is looſe and ſandy, the trees muſt be planted in holes: all other ſoils muſt be fallowed and pulverized by frequent plowings and harrowings; grounds of a middling quality after graſs, will require a ſummer and winter's labour at leaſt, an obſtinate clay not leſs than two. The common nurſe for the better kinds of foreſt trees in expoſed ſituations is the Scotch Fir: the different kinds of Poplars, and the great Maple or Sycomore, are very fit for this purpoſe, as they are of quicker growth than Firs, and may be planted of large ſizes on the pooreſt lands with ſafety. The beſt ſeaſon for planting light grounds, is as ſoon as poſſible after the beginning of october; for the moiſt and heavy, february and march.

Let every quarter of your Wood be bounded by a row of Poplars at two or two and a half feet aſunder; in the heavieſt and wetteſt places, let them be of the Lombardy ſort; in thinner and lighter, of the white. Theſe ſhould be either rooted, or cuttings four or five feet high. If the whole ground is to be planted, without being divided by ridings or walks, having firſt gone round it, let lines of Poplars running from ſouth to north be planted at one hundred, or in very expoſed ſituations at eighty feet aſunder.

In order moſt effectually to promote the growth of the more valuable trees, every ſecond line may be of Sycomores; not next the Poplars, but among the trees intended for a longer continuance.

The diſtance of the trees in the Wood, at a medium, ought to be five feet every way; for plants may be too much crowded or drawn, as well as too much expoſed.

Having planted half your intended Wood with Sycomores, in rows ten feet aſunder and five in the row; proceed to plant, in the moſt generous deep but dry ſoils the Walnut, with Engliſh, Scotch and Corniſh Elms; in the moiſt and heavy, the Dutch Elm; in coarſe and ſtony the Cheſtnut and Aſh; in light and ſandy the Larch and Beech; and in clays of all qualities, though ſwampy and moſſy, the Oak. If a little orna-

Digitized by Google

ment and variety is wiſhed, a ſmall mixture of the hardy American trees may be added.

Where the ground is various, and the trees thus adapted to the different ſoils; the groups of different trees in the ſeveral quarters will appear far more chearful and pictureſque than one uniform Wood of the ſame kind.

In mountainous rocky ſituations Firs are the greateſt improvement, planted not above three years old, when after two years growth Oaks and other trees may be interſperſed wherever the land will receive them.

Some adviſe that the beſt manner of raiſing Woods is by ſowing the ſeeds on the ſpot. But of this I cannot approve, becauſe, firſt, it is a very tedious practice, allowing it to ſucceed, which on many occaſions it will not. 2. Becauſe the ground muſt be as well prepared and kept as clear of weeds as in the nurſery; the land as regularly dug about the plants, and in all reſpects as well cultivated as theſe. 3. It is a ſmall proportion of the ſeeds ſown that can remain in the Wood to make trees, and theſe are generally much injured from the others ſtanding cloſe together about them. 4. The expenſe is much greater in the end, than at once making a handſome finiſhed plantation. I am therefore againſt raiſing a Wood after this manner, except with the Walnut, Cheſtnut, evergreen Oak, and a few of the other nut-bearing trees, that do not eaſily remove, or grow freely after it.

Others argue for planting ſeedlings two years old, as the moſt hardy, and likely to ſucceed in cold barren ſoils; but ſuch having a downright tap-root, with few ſmall roots, or fibres, being young and tender from a warm ſeed-bed, and immediately expoſed to a bleak ſituation and a cold ſoil, cannot be likely to thrive ſo well as plants that have been inured gradually to the inclemency of the ſeaſons, and coarſer fare. Having then planted your nurſing trees, and rejected both the ſowing of ſeeds and planting of ſeedlings, let your plants be four or five years old: ſuch will be able to get the better of all weeds, except the large-growing ſorts. When theſe plants have ſtood four years, take away every ſecond Sycomore, and in two years more, the remainder, with every ſecond tree of the other kinds, which will leave the whole plantation at ten feet aſunder. The trees which are taken away may be planted on the farms in hedge-rows, &c.

In eighteen or twenty years three-fourths more of the remaining trees, and all the Poplars muſt be taken away, which reduces them to twenty feet aſunder.

It has been an almoſt univerſally received opinion that trees ought to be raiſed in the nurſery on a poorer ſoil than that to which they are afterwards to be tranſplanted. On the contrary it is neceſſary to promote their vigorous growth at firſt, in order to their becoming ſtately and handſome; nor can this be effected by any other means than being early nurſed in a generous ſoil; for if they are barely ſupported in meagre ground, they will never after become ſtrong, when removed to that which is rich. From their harſh and unfriendly food they get bad roots, are hide-bound, and have weak crooked branches. But though trees ſhould be raiſed on good land, yet it muſt be ſuch as is naturally ſo, not what has been forced and pampered with dung.

Dr. Hunter, of York, has made the following obſervations on raiſing Woods from ſeed.

In Scotland and ſome of our northern counties, the practice of raiſing Woods in waſte lands, by ſowing acorns, cheſtnuts, beechmaſt, fir-ſeeds, aſh-keys, &c. is much recommended. The expenſe attending it is trifling, when compared with that of planting. Charles Turner, Eſq. of Kirkleatham, in the county of York, has within theſe few years ſown upwards of four hundred acres of waſte and moor land, with the various ſeeds of foreſt trees. In the neighbourhood of coal and lead mines, and iron forges, ſuch Woods will become highly profitable at an early period. Mr. Turner's eſtate at Kildale may ſerve as an example to ſuch gentlemen as wiſh to bring their weak, rocky and moor lands into the moſt profitable cultivation. Here the turf was taken up with a paring ſpade, the earth was ſtirred, the ſeeds were put in and covered. In ſome places ſeedling Firs, Larches, and Oaks were ſet inſtead of ſeeds. Such work ſhould be performed early in the ſpring; and in lands that ſwell after froſts, the turf ſhould be removed and the ſoil ſtirred the autumn before. Moor earth, being very looſe, ſhould be well ſtirred, the plants put in very early, and care taken to preſs the earth well to their roots.

When a large tract of land is deſigned for Wood, eſpecially if it be of an indifferent quality, it may be thus managed; plough it in october or november, and in the following ſpring plough and harrow ſo as effectually to deſtroy the turf. Sow it with turnip-ſeed about the third week in june; hoe the crop well, and if poſſible let it be fed off with ſheep. If another crop of turneps be taken the ſucceeding year, the land will be in excellent condition for receiving the ſeeds of Foreſt-trees. Some ſow them with oats, and others take a crop of ſpring rie with acorns. Certain it is that trees raiſed thus from ſeed will make better timber, and come ſooner to maturity, than when they are drawn from a nurſery.

As much depends on keeping the ſeedling plants clean, drill ſowing is much preferable to broad-caſt, becauſe they may thus be horſe-hoed at a ſmall expenſe.

Such as plant on a great ſcale, will find much inſtruction in the account of the plantations made on the Duke of Portland's eſtates in Nottingham Foreſt, by Mr. Speechly, his grace's gardener.

The ground is a continuation of hills and dales; the ſoil chiefly gravel on the former, and ſand in the latter. The Woods are planted on the hills.

When the part intended to be planted is fixed upon, ſome well-ſituated valley is choſen as near the centre as may be, for a nurſery. Here a piece of ground of a proper ſize is fenced ſo as to keep out all noxious animals, a carriage road is left through the middle, with boarded gates at each end. The reſt of the ground is trenched about twenty inches deep, which may be done for three pounds ten ſhillings or four pounds an acre: this work is beſt done in ſpring, when the planting ſeaſon is over. If after trenching, two or three chaldrons of lime be laid on an acre, the land will produce a crop of cabbages or turneps, which being eaten off by ſheep, will make the land in fine order, and it will require nothing more than a common digging.

If an Oak Wood is intended to be raiſed, draw drills a foot from each other, after every fifth row leaving a ſpace of two feet for the alleys. In theſe ſow the acorns ſo thick as nearly to touch each other. When the tops of the rows meet, take away one row on each ſide the middleмoſt, which leaves the remaining three rows the ſame diſtance apart as the breadth of the alleys. In taking them up do not injure the roots. When the tops meet again, take up every other row, leaving the reſt four feet aſunder, till they arrive to the height of about five feet, which is as large as they ſhould ever be planted. In taking up theſe, dig a trench at the end of each row full two feet deep; then undermine the plants and let them fall into the trench with their roots entire, much of their future ſucceſs depending on their being well taken up.

Go over the nurſeries every winter to ſhorten the ſtrong ſide ſhoots, and to take off one of all ſuch as have double heads.

The ground intended for Woods ſhould be fenced at leaſt a year before it is wanted; and got into order for a crop of turneps; two chaldrons of lime ſhould be laid on an acre, which will bind the land and make it fall heavy, if it is ſo light as to be liable to be blown from the roots of the young trees. Part of the turneps ſhould be eaten off early in the autumn, forward planting generally ſucceeding the beſt.

This being done, plough the ground with a double-furrow trenching plough to the depth of twelve or thirteen inches; which will be of great ſervice to the plants, and ſave much trouble in making the holes.

The planting ſeaſon being arrived, as ſoon as the plants are taken up, dig a trench at leaſt fifteen inches deep, and ſet the young trees in it with their tops aſlant, covering

Digitized by Google

covering their roots as you go along, and almoſt half way up the ſtem, with the earth that comes out of a ſecond trench, which fill in like manner, and ſo on, till you have about a load in a heap. In light ſoil this trouble is but little, and the plants are always ſecure from the roots drying or freezing. A low-wheeled waggon will carry them from the heaps to the pruners, who ſhould have a portable ſhed to work under; which is alſo convenient to ſhelter the other men in ſtormy weather. Cut off all the branches cloſe to the ſtem to about half the height of the plant, ſhortening the reſt of the top to a conical form in proportion to the ſize of the plant: in pruning the roots only cut off the extreme parts that have been bruiſed by taking up, or ſuch as have been damaged by accident; planting with as much root as can be had.

As ſoon as they are pruned, let them be taken to the planters by the carriers, who are generally a ſet of boys, with ſome of the worſt of the labourers. The planters go in pairs, one making the holes, the other ſetting and treading the plants faſt, which work they commonly do by turns. In making the holes throw out all the bad ſoil that comes from the bottom; if the planting be on the ſide of a hill, throw this on the lower ſide of the hole; ſo as to form a kind of baſin, in order to ſtop the rains. Make the holes ſufficiently large, throw a few ſpadefuls of the top ſoil into the hole, ſetting the plant with its top rather inclining to the weſt; then fill up the hole with the beſt top ſoil, taking care that it cloſes well with the roots. When the hole is well filled up, let one of the planters tread and faſten the tree firmly with his foot, while his partner proceeds to make the next hole. This faſtening is much to be attended to, for if the tree once becomes looſe, the motion occaſioned by the wind will deſtroy the fibres as faſt as they are produced: and it is to guard againſt this, that ſo much of the top is taken off.

Three or four hundred Birches of a large ſize may be planted on an acre, with nearly the ſame number of the firſt ſized Oaks; and here and there a Beech, Larch, Spaniſh Cheſtnut, &c. beſides patches of Hollies, Laurels, Yews, Junipers, &c. on the outſides of the Woods, intermixed with Tulip-trees and other rare trees, and Cedars of Lebanon at good diſtances: and within, other patches of Beech, Larch and Spaniſh Cheſtnut; altogether producing a good effect on unequal ground by a diverſity of tints and ſhades. After this a quantity of ſmaller ſized Oaks may be planted; and laſtly a conſiderable number of ſmall Birches; which may be removed to ſucceeding plantations after five or ſix years. Thus upwards of two thouſand plants of different kinds of trees are ſet upon an acre of land in an irregular manner.

After the whole planting is finiſhed, ſow acorns all over the plantation, except in the patches, in ſhort drills of about a foot in length; theſe probably at laſt will make the beſt trees.

The planting ſhould, if poſſible, be finiſhed by the end of february.

Towards the end of april, when the ground is moiſt, go over the whole, and faſten all ſuch trees as are become looſe. In june cut off all tall-growing weeds with the hoe; but in very light lands, the ſooner the ground is covered with graſs the better. On ſome lands it is certainly better to plant in rows, and to keep the ground clean hoed; but in light ſands, the ſoil by this method will frequently be carried by the winds into the vallies, and the plant will be apt to miſcarry in a dry ſeaſon. Nay it is no bad way on ſuch lands to ſow furze, as ſoon as the planting is done[1].

Cut down the tall-growing weeds two or three times the firſt ſummer, and once the next. The winter after planting, fill up the places with freſh plants where they have miſcarried: after which there is little to be done till the fourth or fifth year; by which time the ſmall-ſized Birch, and ſeedling Oaks will be grown to a proper ſize for tranſplanting: too many muſt not be taken away in one ſeaſon, but by proper management there will be a ſupply of plants for at leaſt half a dozen years to come.

[1] This is recommended by Evelyn, chap. 2.

About the time that the ſmaller Birches want thinning, the large ones will require to have their lower branches taken off, to keep them from injuring the Oaks: and this is the firſt profit of the plantations, the Birch-twigs being readily bought up by the broom-makers. Continue this pruning till the Birches are grown large enough for fencing rails, then cut them down.

By this time the Oaks will be grown to the height of twelve or fourteen feet, and will draw up very faſt. They muſt then be thinned from time to time, and their dead branches cut off: but the thinning muſt be done with caution, and they may be left very cloſe for the firſt fifty years. In twenty-eight years the Oaks will be twenty-five or twenty-ſix feet in height, and in girth eighteen inches: in fifty years they will be ſixty feet in height and upwards, and above three feet in girt: from their cloſeneſs, theſe trees will be fifty feet in the bole.

The Earl of Fife's plantations were begun about the year 1757. They conſiſt of about ſeven thouſand acres of bleak and barren moor in the counties of Aberdeen, Bamff, and Moray. He began firſt with incloſing his park at Duffhouſe in the county of Bamff, where there was not a tree, and it was generally believed that no Wood could thrive ſo near the ſea coaſt: he has however now every kind of foreſt trees in it, from thirty years old, in a moſt thriving ſtate.

In planting his barren moors, where there are ſtones, he incloſes with a ſtone wall five feet high, coped with two turfs, which coſts about fifteen ſhillings every ſcotch chain of twenty-four ells; and where there are no ſtones, he incloſes with a fence of turf, five feet high, four feet wide at the foundation, and twenty-two inches at top, at four ſhillings the ſcotch chain. He finds theſe to anſwer as well as the ſtone, there being many of them above twenty years old, as good as at firſt.

He plants in every acre about one thouſand two hundred trees. He uſed to plant above three thouſand, but by experience he finds it better not to plant ſo thick, making them up, if neceſſary, the third year. The greateſt number of the trees are Scotch Firs, raiſed by himſelf, or purchaſed at tenpence the thouſand, planted from the ſeed-bed at three years old. He only conſiders theſe as nurſes to his other trees, and regularly cuts them out, when they have done their duty, and are profitable for firing, or uſeful in agriculture. He plants every other ſpecies of foreſt trees intermixed with the firs.

He orders different pieces of the moor to be trenched where the ſoil is beſt, and moſt ſheltered, a little lime and dung to be laid on, and ſeeds of trees to be ſown there for a nurſery. He alſo plants in beds, year-old trees of different kinds, taken from his other nurſeries; and after they have been there three years, diſperſes them all over his plantations: this he finds very beneficial, as they are raiſed in the ſame ſoil.

When he is filling up the plantation, the Firs are then, for the firſt time, cut down; or they are tranſplanted, being raiſed with balls of earth, when the moor is wet with rain, which is very eaſily done, and they are carried to incloſures of ten or twelve acres, where from a deſire of forward woods, he plants trees more advanced. —They are planted in pits about forty feet diſtance, ſeldom or ever fail, and anſwer a ſecond time as nurſes.

A ſmall allowance to a few labourers ſerves to guard the incloſures againſt injury from cattle; and if the fences are properly executed, they require very little repair.

The moſt regular attention muſt be had to weeding the plantation, the value and proſperity of the Wood depending upon this being done at all ages, in the moſt exact manner. In order to facilitate this, roads are made through all the plantations, according to the ſituation, but never in a ſtraight line, ſo as to draw violent winds: theſe roads make agreeable rides through fine Woods, formerly a bleak moor, and anſwer both for filling up vacant ſpaces, and carrying away the weeds.

He begins to plant in october, and continues till april: if the weather is froſty and not fit for planting, all the people are employed in weeding.

Weedings of Aſh, Oak, Elm, and Beech, from twenty to thirty years growth, are worth there

Digitized by Google

from ſeven ſhillings to ten ſhillings a tree. The number of trees to be left, ſhould entirely depend on their not touching each other, ſo as to bruiſe the branches.

With proper management the weedings may not only pay the expenſe for thirty years, but more than any yearly rent; and the timber then ſtanding, will be of great value, increaſing every year, and ſo much gained: but all this depends on judgment in weeding, and not over pruning, ſo as not to have too many trees ſtanding with amputated limbs.

Every kind of tree thrives in the moors, when ſheltered by Scotch Firs: where there are hollow or loamy ſandy places, Oak, Beech, Aſh, Elm and Larch mixed may be planted, without the Firs being ſo thick as on harder ground. The Firs afford both ſhelter and moiſture, advancing the other trees greatly, only they muſt not be allowed to overtop them, ſo as to keep them from air: they are alſo the beſt nurſes, becauſe where they are pruned they never put out another branch; and when cut down, the roots die, and do not rob the ground by any farther growth.

A mixture of trees is beſt in any ſoil, and when any fail, they can be filled up with trees that are found to thrive beſt. The Larch and Silver Fir, planted about three years old, thrive better than any tree, and grow to a great ſize. Where ground is unequal, the hills may be covered with Larch, the hollows with Silver Firs, and the flat with different mixed trees.

Plantations ſhould be thinned, whenever the branches touch. The principal object is early weeding (thinning). Many perſons, inſtead of this, prune their trees; but this I think ruinous, as the vigor of trees depends on the limbs.

In plantations about twenty years old, it may be neceſſary ſometimes to grub the roots of trees that are too near; but if they are regularly thinned, this will not be often required, as the large trees, with vigorous branches, will keep the underwood down.

Planting all kinds of trees, that are intended to ſtand, is better than ſowing them: for trees from ſeeds ſown never grow ſo well as when they are properly mixed, and planted in ſoils which they thrive beſt in.

When ground is better than in the moors, and the extent not ſo great, it ſhould firſt be ploughed, and then a kind of fallow given it with the break-harrow, to deſtroy the couch, and make it as clean as poſſible. A little lime is of great ſervice. When the ground is in good order, plant it with ſuch trees as you chooſe from four to ſix feet high, at eight or ten feet diſtance. The whole muſt be hoed three or four times a year, during ſix or ſeven years. In that time, ſuch trees as can be ſpared may be removed to other plantations, where they are ſheltered; and in about ſeven years the plantations will ſhade the ground, and prevent the couch from doing any injury. You will then have only to tranſplant or cut where the trees are ſo thick as to interfere.

Trees planted among furze or broom receive no injury from them, but, if they thrive, ſoon get the better of them, particularly Firs. Wet places ſhould always have drains to carry off the water; for although moiſt ground may be good for ſome trees, yet ſtagnated water always injures; and the couch, ruſhes, &c. where water is not conveyed away, are deſtructive.

Nothing is more dangerous than improper pruning of trees that are intended to ſtand for timber. No Fir-tree ſhould ever be pruned, unleſs to cut off the branches near the ground: all other trees ſhould be pruned with a friendly hand; and only the branches taken away that rival the growth of the trunk; in general, theſe branches are near the ground.

Autumn is to be preferred to the ſpring for ſowing, but ſo as that the froſts may be over before the plants appear above ground. The earth is the beſt preſerver of ſeeds; every ſeed which has a bark, is beſt preſerved in that: others may be kept in bags or boxes, always taking care not to exclude them too much from air.

Cattle ſhould not be permitted to paſture in plantations, ſo long as the branches of the timber trees are within reach, or any advantage is to be got from the underwood [k].

[k] Young's Annals, 9. 107. and 10. 529.

Mr. Marſhall is copious upon the article Woodlands [l]. For the purpoſe of raiſing timber for ſhipbuilding, where crookedneſs is required, he recommends open Woods. He might have added that hedge-row timber will alſo anſwer that purpoſe: and though crooked timber is wanted for knees, yet much clean ſtraight ſtuff is required for beams, plank, &c. Where ſtraightneſs and length of ſtem, and cleanneſs of grain are wanting, cloſe Woods or Groves are more eligible; and where ſtub-wood is the principal object, coppices unincumbered with trees, are moſt adviſeable.

Mr. Marſhall reconciles the diſpute about ſowing or planting, in order to raiſe Woods in the following manner. Where the ſtrength of the land lies in the ſubſtratum, whilſt the ſurface ſoil is ungenial, by all means ſow, that the roots may ſtrike deep: but on the contrary, when the top ſoil is good, and the bottom of an oppoſite quality, plant, or elſe ſow and tap the young plants as they ſtand, to check their downward tendency, and ſtrengthen their horizontal roots. How far this theory may anſwer in practice I know not, but I muſt own that I have a predilection for ſowing, or ſetting the acorn itſelf, in order to raiſe good large timber for ſhipbuilding and other great purpoſes. In foreſts, the buſhes and fern may be made uſe of ſucceſsfully for rearing trees from the falling acorns and maſt; or nature may be aſſiſted by inſerting acorns among the buſhes in proper places.

As to the comparative expenſe of ſowing and planting, Mr. Marſhall obſerves that two things are to be conſidered: the actual expenſe of labour and other contingent matters, and the loſs of time in the land occupied. With reſpect to the former, ſowing is beyond compariſon the cheapeſt method; but in regard to the latter, planting may ſeem to have a preference; for the ſeed-bed is ſmall compared with the ground to be planted, and whilſt that is rearing the ſeedling plants, this continues to be applied to the purpoſes of huſbandry. However if we conſider the check which plants in general receive in tranſplantation, and if the void ſpaces of an infant Wood may, for ſeveral years after ſowing, be ſtill cultivated to advantage, the preference is evidently on the ſide of ſowing.

As to the arrangement of the wood plants, againſt ſteep hangs, where the plough cannot conveniently be uſed, the ſeeds may be ſown at random, or if plants be put in, the quincunx manner will be preferable to any: but in more level ſituations the drill method is the moſt eligible, for the ſake of keeping the infant Wood clean at the leaſt expenſe.

Where a conſiderable tract is intended to be converted into Woodland, the whole quantity of land ſhould be aſcertained, and divided into annual ſowings, to be regulated by the uſes to which the underwood is to be put, in order to produce a regular ſucceſſion of annual falls. Theſe muſt be fenced, not only againſt cattle and ſheep, but hares and rabbets. The ſort of fence muſt be determined by the materials which the country affords.

If the ſoil be ſtiff, it ſhould receive a whole year's fallow, as for wheat; if light, a crop of turneps may be taken: at all events, it muſt be made perfectly clean, particularly from perennial root-weeds, before the tree-ſeeds are ſown. If the ſituation be moiſt, the ſoil ſhould be gathered into wide lands, not high, but ſufficiently round to prevent ſurface water from lodging upon them.

October and november are the fitteſt months for the autumnal, and march for the ſpring ſowing: but attention ſhould be paid to the ſeaſon, and the ſtate of the ſoil.

The land being in fine order, and the ſeaſon favourable, the whole ſurface ſhould be ſown with corn or pulſe adapted to the ſeaſon; as wheat or rie in autumn, beans or oats in ſpring. The quantity of ſeed ſhould be leſs than what is commonly ſown for a crop, in order to give a free admiſſion of air.

The tree-ſeeds muſt then immediately be ſown in lines or drills acroſs the lands: acorns and nuts ſhould be dibbled in, whilſt keys and berries ſhould be ſcattered in drills, as garden peas are uſually ſown.

[l] Planting, vol. 1. 120. ed. 2. 1796.

Digitized by Google

The diſtance between the rows may be a quarter of a ſtatute rod, that is four feet one inch and half. Stakes being driven at the ends of theſe, a line is ſtretched to dibble or draw the drills by. If the plot be extenſive, glades for the purpoſe of roads, ſhould be left at convenient diſtances.

The ſpecies of underwood muſt be determined by the conſumption or demand. The moſt proper tree for theſe open Woods is the Oak. The uſual ſpace allowed to timber trees among underwood is thirty feet; two rods or thirty-three feet will not be found too great a diſtance.

The Oak and Hazel riſing the firſt year will be viſible at harveſt; but Aſh keys lying two and ſometimes three years, their drills muſt have ſome mark to diſtinguiſh them, to prevent their being diſturbed in ploughing the intervals. If beans be the crop, a few oats may be ſcattered among the keys for this purpoſe, or the contrary.

The crop ſhould be reaped, not mown, and carried off with all convenient care.

The ſecond year's crop may be potatoes, cabbages or turneps, according to the ſoil. Or, if the firſt was corn, this may be beans, and the contrary.

The tree-drills muſt be kept perfectly clean by weeding and hand-hoeing.

In the ſpring of the third year, look over the drills of Oak and Hazel, and fill up vacancies from the parts where plants are ſuperfluous: deferring thoſe of the Aſh to the fourth year.

If ſeedlings be wanting for laying into hedges, and filling up corners, or if they ſhould be ſaleable in the country, the ſuperfluous ones may be drawn out in the ſpring of the third and fourth year, and tranſplanted into ſome vacant ground.

The firſt cutting ſhould be timed by the plants themſelves. Whenever the rows of Oaks intended for timber, are in danger of being drawn up too much, the whole muſt be cut down to within a hand-breadth of the ground, except the Oaks intended for ſtands, which ſhould now be ſet out at their proper diſtances, as near in a quincunx order as the beſt plants will allow.

The young ſtands will require to be more or leſs pruned: the lower ſide ſhoots muſt be taken off, and their heads reduced, ſo as to prevent them from being top-heavy. But if the firſt fall is made in due time, their heads will want little pruning. In tranſplanting, the roots have freſh fibres to make; but here they are fully prepared to ſend up the neceſſary ſupplies, and the more top there is to promote the aſcent, the quicker progreſs the plants will be enabled to make.

The firſt fall therefore muſt by no means be deferred until the plants be drawn up too ſlender to bear a well-ſized top; for they will then be apt to ſtoop under the weight of their own leaves, and to be bowed to the ground by a ſhower of ſnow.

The ſecond fall ſhould be timed according to the ware which the country calls for: only the timber trees muſt not be injured by being crowded by the underwood: rather than this ſhould be the caſe, the coppice wood muſt be felled, even though it ſhould not have reached its moſt profitable ſtate.

After the ſecond and every ſucceeding fall of underwood, the timber ſtands ſhould be gone over, their leaders kept ſingle, and their heads ſet up, until the ſtems have reached the height of fifteen or twenty feet; when their heads ſhould be permitted to ſpread, and take their own natural form.

In raiſing a Wood againſt a hang too ſteep to be cultivated with the common plough, after the wood-ſeeds are ſown; but which may be fallowed and brought into proper tilth by the turn-wreſt plough: the planter has his choice, to ſow, to put in ſeedlings, or tranſplanted trees. In the firſt, the expenſe of cleaning by hand will fall heavy; and in the laſt, the labour of the nurſery will not be leſs burdenſome. The middle path therefore is moſt adviſeable.

The ſeedling plants may remain until the third year in the ſeed-bed; by which time they will have acquired ſufficient ſtrength to ſtruggle with the lower order of weeds. They may be ſet irregularly or in drills: and acorns may be dibbled in among them to inſure ſucceſs.

If the hang is ſo very ſteep or ſo ſtrong, that even the turn-wreſt plough cannot be uſed, ſeedling plants, and acorns or other tree-ſeeds may be put in, without any previous preparation, except that of clearing away buſhes, and burning off the weeds and rough graſs. In this caſe, the number of plants, and the quantity of acorns, ſhould be greater than when the ground has been prepared by a fallow.

In the ſouthern counties, Mr. Marſhall ſays, he has ſeen the Oak riſe fortuitouſly, or with little aſſiſtance of the woodman, to timber of the firſt quality. In the midland counties, he has examined Oak Woods of different ages, which were propagated by ſowing acorns with arable crops, or by ſetting them in the turf of graſs land, and leaving the young plants to nature; and this with good ſucceſs. In the Highlands of Scotland, he has obſerved mountainous diſtricts covered with planted trees of various ages and ſpecies; and this too with a ſucceſs, which, ſeeing the inaccurate manner in which they are frequently put in, and the neglect they afterwards experience, is almoſt incredible. Nevertheleſs he ſtill remains an advocate for the practice of treating young Woods as nurſery grounds; becauſe by keeping the ſoil in a ſtate of tilth, and free from weeds, much time is gained in their early growth, and a ſtrong vigorous habit is given to the youthful plants; and becauſe a favourable opportunity is thus obtained for removing ſupernumerary plants for ſale, or for other plots of planting, or for filling up vacancies in parts too thinly ſtocked.

In planting Woods without underwood, which Mr. Marſhall calls Timber Groves, not only the Oak, but any other trees adapted to the ſoil may be introduced, as the Cheſtnut, the Walnut, the Aſh, the Elm, the Beech, the Cherry, the Larch; and of aquatics, the Poplars, the Willow and the Alder.

The Elm, Cheſtnut, Walnut and Cherry require a good ſoil and mild ſituation; the aquatics of courſe will be confined to moiſt low grounds; the Beech and Larch will thrive in bleak barren places; whilſt the Oak and Aſh can accommodate themſelves to almoſt any ſoil or ſituation; though they ſeldom riſe to profit on bleak and barren ſites.

The Scotch Fir is properly a mountain tree, and ought only to be planted on bleak and barren heights, and even there the Larch is found to outbrave it. In better ſoils and milder ſituations, the wood is worth little, and it is unfit to be aſſociated with other timber trees: it ſhould therefore only be introduced in ornamental ſcenery, or as a nurſe for more valuable timber.

Mr. Lambert, in his elaborate and ſplendid work on the genus Pinus, ſays, it is ſurprizing that this ſpecies is not more cultivated in waſte grounds, as the few planted on Bagſhot and Hounſlow heaths, &c. ſucceed ſo well. Mr. Davis, in the ſame book, affirms that the Scotch Fir raiſed in England is equal to the foreign in weight and durability, but is ſeldom ſo fine in the grain, and has a greater quantity of ſap owing to its rapid growth, occaſioned either by the ſuperior ſtrength of the land, or by being planted at greater diſtances, or both. But the quality is ſufficiently ſimilar to aſcertain that they are the ſame ſpecies. A foot ſquare of this wood, engliſh growth, and moderately dry, will weigh fifty-one; and a foot of Oak not much more than ſixty-one. A tree one hundred years old may meaſure four loads, or two hundred feet, and is fairly worth fifteen pounds. Land planted with Scotch Firs eight feet and a quarter apart, or ſix hundred and forty to an acre, will pay ten per cent compound intereſt, ſuppoſing very poor land at three ſhillings an acre, worth about four pounds in fee, and the planting to coſt ſix pounds more. In twenty-eight years ten pounds at compound intereſt will be forty pounds, and in that period the trees, at only two and ſixpence each, will be worth eighty pounds.

Spruce Firs, according to Mr. Davis are perhaps next in value to Scotch Fir, and what is remarkable, thoſe grown in England are ſuperior to any imported. Not being hurt by knots, it is the better for rapid growth, and the deal is the handſomer. It does not grow well in expoſed ſituations, but loſes its ſide

Digitized by Google

branches, becomes moſſy, and dies: if planted too cloſe, it never riſes to any ſize. Mr. Miller ſays they ſhould be ſet eighteen or twenty feet aſunder. Nothing can be more pleaſing to the eye than fine lofty Spruce Firs, feathered down to the ground, ſcattered over a carpet of graſs cropped cloſe by ſheep; as may be ſeen in ſome parts of Switzerland.

The Silver Fir, the moſt beautiful in external appearance of all the genus, either young or old, grows much faſter than either of the above. At one hundred years old it is frequently above one hundred feet high, twelve or thirteen feet round, and contains at leaſt ſix loads of timber, worth about fifteen pounds. The Wood is more open than the Spruce, and therefore ſhould be uſed in large ſcantlings, where its ſtrength and toughneſs render it a valuable wood, particularly for beams; only great care muſt be taken that the ends are dry and acceſſible to air. I have experienced what Miller ſays to be true, that the young ſhoots are often killed by ſpring froſts.

The Weymouth Pine is ſtill lighter and more open in the grain. Its principal uſe is for maſts of ſhips, for which its toughneſs makes it proper. It will, in ſtrong land well ſheltered, get to four or five loads in one hundred years, worth eight or ten pounds. In America this tree attains two hundred feet in height. It does beſt here in ſheltered crevices and receſſes of mountains.

Mr. Davis remarks, that it is a miſtake to ſuppoſe that Fir trees ſhould be cut in ſummer, becauſe the ſap is then afloat; whereas they ſhould always be cut when the ſap is ſtagnant, namely in winter. Fir cut in ſummer will become full of muſhrooms in twelve months after.

Mr. Davis does not ſeem to have been fully aware of the value of Larch, which is now generally acknowledged. *See our article* PINUS LARIX.

The Oak, Aſh, coarſe-leaved Elm, Beech, Cheſtnut, Walnut and Cherry, may be raiſed in drills, in the manner already preſcribed, except in the method of training. The Pines being of a hazardous nature, when in their infant ſtate, it is adviſeable to raiſe them in ſeed-beds, and ſet them out as ſeedling plants. The fine-leaved Elm muſt be raiſed from layers, and the aquatics from ſets or cuttings.

When Grove-timber is raiſed by ſowing in drills; if ſeedling plants be wanted, the rows may be thinned the third and fourth years, until the remaining plants ſtand from twelve to eighteen inches apart. This done, nothing will be requiſite, until ſome kind of ware can be cut out, as edders, hoops, ſtakes, &c.

In this ſtage of growth, the rows ſhould be gone over every winter, and all the underling plants cut out, within the ground, if practicable, which will in general kill the roots, and ſave the expenſe of grubbing. If the remaining plants are not already too much crouded, thoſe which yet ſtruggle for the light ought to be left, to aſſiſt in drawing up, with greater certainty, thoſe which have gained the aſcendancy.

This conduct ſhould be obſerved, from the time of the firſt cutting, until the trees are ſet out, at diſtances beſt ſuited to their reſpective natures, and according to the accidental tendency which they happened to take in riſing.

The thinning of a timber Grove ſhould be directed by the ſtrength of the plants, and the uniformity of the canopy, taken jointly. The woodman's eye ought therefore to be directed towards the tops, rather than to the roots of his trees.

If the Grove be thinned too faſt, its upward growth will be checked, and the length of the ſtem curtailed: if on the other hand the thinning be neglected, or be performed too leiſurely, the plants will be rendered too ſlender, and thereby become liable to laſh each other with every blaſt of wind. This evil is called whipping of tops, and many fine Groves have been very materially injured by it. Whenever two trees are ſeen to be engaged in this conflict, one of them ſhould be taken down without loſs of time.

If the thinning be conducted with judgement, little pruning will be neceſſary; ſome however will be found requiſite: ſtrong maſter plants are liable to throw out ſide branches, to the annoyance of their neighbours: they ſhould be taken off in time, and all dead branches removed, eſpecially thoſe of the Pine tribe; otherwiſe the heart of the timber will be rendered coarſe, knotty, and of a bad quality. The leaders ſhould alſo have due attention paid to them; particularly if a group of foul-headed plants happen to fall together; for in this caſe, if nature be not aſſiſted, a timber tree will, in the end, be wanted.

This method of training holds good, whether the Grove be raiſed from ſeeds, or from ſeedling or other plants: and whether theſe be arranged in drills, or ſet promiſcuouſly; provided the body of the Grove be formed of one ſort of timber tree.

With regard to miſcellaneous Groves, ſo many evil effects ariſe from injudicious mixtures of timber trees, that it ſeems beſt to condemn them at once. It may be ſaid, however, that by aſſociating trees of different natures, the ſoil will be made the moſt of; that the Aſh, for inſtance, will thrive after the Oak, and the Oak after the Aſh, in a more profitable manner than either would, if propagated repeatedly upon the ſame ſpot.

This leads to an improvement in the method of raiſing a Grove of Oaks; and the ſame method is applicable to any other ſpecies of tree. Inſtead of ſowing every drill with acorns, let every ſecond drill be ſown with the ſeeds of ſome other tree, Aſh for inſtance: its ſeeds are eaſily procured, and as underwood, no tree is applicable to ſo many uſeful purpoſes.

In this caſe, the method of training is nearly the ſame as that already deſcribed, except that the Aſh muſt be made ſubſervient to the Oak: if the former ſhould riſe too faſt, it muſt be cut down to the ſtub, as underwood; if aſhen ſtands be left to draw up the young Oaks, they muſt be lopt, or taken down, the moment they aſpire to a ſuperiority, or give the neighbouring plants an improper tendency.

When the Oaks have acquired a ſufficient length of ſtem, and have made good their canopy, the aſſiſtance of the Aſhes will be no longer wanted; nor will they be any longer valuable as underwood; they ought therefore to be entirely removed: and if their roots be grubbed up, the Oaks will receive at once a freſh ſupply of air and paſturage.

In bleak ſituations a quicker growing and better feathered plant than the Aſh, affords more valuable protection: the Scotch Fir, kept under due ſubjection, is eligible in this caſe. Furze is ſometimes made uſe of for this purpoſe; but the broom is better, as being leſs offenſive, and at the ſame time more efficacious. Its ſeeds are readily procured; its growth is rapid; it will brave the bleakeſt aſpect; and the natural ſoftneſs of its foliage renders it inoffenſive to work among.

There is one circumſtance obſervable in raiſing Oaks from ſeed: that it ſhould not be attempted when acorns are not abundant, becauſe it will then be difficult to preſerve them from vermin. In a plentiful year, when every Wood and hedge-row is ſtrewed with acorns, thoſe which are lodged in the ſoil are leſs liable to their ravages. The greater quantity alſo there is ſown, the leſs will be the hazard: and for a ſimilar reaſon it may be prudent to ſow the margins of the field thicker than the area, where fewer enemies may be expected.

In raiſing a COPPICE, the firſt buſineſs is to ſet out the plants of proper diſtances, where they are too thick, and to fill up the vacant ſpaces with the ſupernumerary plants.

Something may alſo be afterwards done by judicious thinning. Where the demand of the country calls for the larger articles of coppice ware, many ſtakes, binding-rods, &c. may be cut out, with advantage to the free-ſhooting plants, left to grow up, to ſupply the markets of the diſtrict; which will ever determine the ſpecies of coppice wood.

The Kentiſh coppices, particularly about Maidſtone, being raiſed for the purpoſe of hop-poles, are chiefly of Aſh and Cheſtnut. They are generally cultivated in rows; the intervals, to keep them free from weeds and the ſoil mellow, are thickly covered with hop-binds, which when they are ſufficiently tender, are dug under as manure. Furze, broom or rough buſhes might be uſed for the ſame purpoſe [m].

[m] Marſhall's Planting, 1. 148—182.

The

The decreaſe of Wood in this iſland has lately excited a conſiderable alarm, from the fear eſpecially that there will ſoon be a great ſcarcity of large Oak timber for naval purpoſes.

Britain, like every other country capable of producing trees, is deſcribed in the earlieſt account of it, to have been covered with wood: and even when domeſday book was compiled, the woods were ſo numerous and extenſive, as to be valued, not by the quantity of timber, but by the number of ſwine which the acorns and maſt could maintain.

Four hundred years after this, in the time of king Edward the fourth, an eminent writer ſays, that England was even then an overgrown country [n].

The firſt attack made upon foreſt trees, of any material conſequence, was in the twenty-ſeventh year of the reign of king Henry the eighth, when that monarch ſeized upon the church lands. But this did not bring with it any pernicious conſequences, the whole kingdom being then ſtocked with all kinds of timber trees, eſpecially the Oak [o].

From the time of Henry the eighth, the conſumption of Oak timber was continually increaſing, not only in conſequence of the extenſion of commerce, and of great additions to the royal navy, but becauſe it was made more uſe of in building houſes.

Holinſhed, who lived in the reign of queen Eliſabeth, ſays, that in times paſt, men were contented to dwell in houſes builded of Sallow, Willow, &c. ſo that the uſe of Oak was, in a manner, dedicated wholly unto churches, religious houſes, princes' palaces, navigation, &c. but now nothing but Oak is any where regarded.

After this, in the reign of king James the firſt, it appears that there was great ſtore of timber, more than proportioned to the demand. For on a ſurvey of the royal foreſts, &c. in 1608, we find that a great part of what was then intended to be ſold, remained a conſiderable time undiſpoſed of [p].

During the civil war in the time of king Charles the firſt, and all the time of the interregnum, the royal Foreſts, as well as the Woods of the nobility and gentry, ſuffered much, ſo that many extenſive foreſts had, in a few years, hardly any memorial left of their exiſtence but their names. From that period to the preſent there is reaſon to apprehend, that the perſons appointed to the ſuperintendance of the royal foreſts and chaſes have not always ſtrictly attended to their charge. But if they had, the various rights claimed by numerous perſons upon them, have made it next to impoſſible that there ſhould be a proper ſucceſſion of good large timber fit for naval purpoſes. This loſs would not have operated ſo ſeverely, had the principal nobility and gentry been as ſolicitous to plant with judgement, as to cut down their Woods. This reflection indeed ſhould be made with ſome limitation: the publication of Mr. Evelyn's Silva in 1664, raiſed a great ſpirit of planting, and in his dedication to king Charles the ſecond in 1678, that gentleman obſerves, that he needs not acquaint the king, how many millions of timber trees have been planted in his dominions, at the inſtigation, and by the ſole direction of that work. The government at that time, alarmed by the devaſtation which had been committed during the civil war, gave great attention to the increaſe and preſervation of timber in the royal foreſts, particularly the foreſt of Dean; and as it is generally allowed that Oak trees, to grow to a ſize fit for the navy, require from eighty to a hundred and fifty years, according to the quality of the ſoil, it is probable that the vaſt quantities of great timber conſumed by our navy, during the preſent reign, were in great part the produce of theſe plantations, or private property in many parts of England, as well as in the royal foreſts. Unfortunately the ſpirit and attention which then prevailed did not continue; and that ſource being now nearly exhauſted, the quantity of timber required for the ſupply of our navy will not be eaſily be found in this country [q].

Several thouſand acres indeed of waſte land have, within thirty or forty years been planted for the benefit of the riſing generation. The Society of Arts, &c eſtabliſhed in 1753, have greatly contributed, by their honorary and pecuniary rewards, to reſtore the ſpirit for planting. The republication of Mr. Evelyn's Silva, in a ſplendid manner by Dr. Hunter, has doubtleſs contributed to that deſireable end.

The following ſketch from the eleventh report of the commiſſioners appointed to inquire into the ſtate and condition of the woods, foreſts, &c. of the crown, publiſhed in 1792 from the Tranſactions of the Society inſtituted at London, for the Encouragement of Arts, Manufactures and Commerce; and from the reports or general view of the ſeveral counties of Great Britain, drawn up for the conſideration of the Board of Agriculture from 1793 to 1797, will give ſome idea of the ſtate of our Woods and timber, both preſent and in expectation, at the end of the eighteenth century.

By the anſwers to queſtions ſent by the commiſſioners of the land revenue to the chairmen of the general quarter ſeſſions of the ſeveral counties in England and Wales, it appears, that the quantity of large Oak timber fit for the uſe of the navy is every where diminiſhed within memory, and very much ſo in many places, both in Woods and hedge-rows: that much more land has been grubbed and converted to tillage, than has been newly planted; that few of the plantations which have been lately made are of Oak, or likely to become of any uſe to the navy; but of Larch, Fir, and mixt trees, preferred for their quick growth, or planted rather for ornament than uſe; that on waſte and commonable lands there is little timber of any value, and that where there is any, great depredations and waſte are committed on them.

It will be a pleaſure to record the names of many patriotic perſons, both among the nobility and gentry, who have ſtrenuouſly exerted themſelves to remedy in ſome degree the increaſing ſcarcity of timber.

Bedfordshire.

There are many Woods, chiefly of Oak, mixed with underwood in this county, but of no very great extent; there is however a ſufficient ſupply of timber for the common wants of the neighbourhood, deal being now ſo generally uſed in building; but underwood becomes rather ſcarce: perhaps as there have been ſo many incloſures lately, in twenty years they may ſupply in ſome meaſure that deficiency. There ſeems to be a prejudice againſt planting trees in the hedge-rows of new incloſures. I have planted many, and ſome thouſands of various trees, as belts, and in corners for ſhelters. The duke of Bedford and lord Oſſory have many fine trees; but I do not know of any conſiderable plantations in this county; where indeed almoſt all the land is well adapted either to corn or paſture. The earl of Upper Oſſory has planted ſixty acres of ſandy heath with Oaks, Cheſtnut, Beech, Hornbeam, Birch, Sycamore, Larch, Spruce, Aſh, Poplar, Alder, and Willow. Francis Moore, Eſq. planted two acres at Aſpley Guiſe with Firs, and twenty acres at Wavendon in Bucks, which ſee. Large plantations of Firs, &c. have been made about Sandy.

Berkshire.

The Woods in this county have not yet been ſo far cleared in the diſtant parts, but that there is ſtill timber to ſupply domeſtic wants. Edward Loveden Loveden, Eſq. made a plantation of ſixty-three thouſand Aſh trees, on upwards of ſeven acres, at Buſcot, near Faringdon.

Buckinghamshire.

From Marlow to Fingeſt, and through that ſpace which is bounded by the road from London to Oxford S. and by the Thames N. one ſixth part of the land is covered with Beech Woods; which require but little attention, as the old trees ſhed a ſufficient quantity of ſeed to keep the Wood conſtantly full of young plants.

In the pariſh of Wycombe, there are ſeven hundred acres of common Beech woodland. William Lee Antonie, Eſq. has very conſiderable Beech Woods in Little

[n] Eleventh report of commiſſioners, 1792. [o] Hunter in Evelyn. [p] Report. [q] Hunter and Report, p. 9.

Digitized by Google

Little Marlow, Medmenham, &c. on the banks of the Thames. In the pariſh of Amerſham are Woods of fine Beech; and in the beautiful park of William Drake, Eſq. there is a variety of thriving timber. Theſe are all chiefly on chalk, and land not very fit for the plough.

The heaths in the pariſhes of Wavendon and Brickhill, which formerly were covered with ſhort heath, were incloſed and planted with Scotch Firs and other timber trees by colonel Moore of Egginton. They are now in a thriving ſtate, and have made theſe barren tracts of greater value than any of the farming land in the ſame neighbourhood. They are in the poſſeſſion of the Duke of Bedford, who has cut rides through them.

Waddon Chaſe, containing twenty-two thouſand acres, is divided into ſeveral Coppices, which are ſhut up for nine years and then laid open for twelve. The produce, under theſe circumſtances, cannot be eſtimated at above three ſhillings an acre; but if it were incloſed, and the underwood preſerved and encouraged, it would yield a profit of ſixteen ſhillings an acre, beſides providing a valuable ſupply of Oak and other timber; large ſticks of which have been ſold from this Chaſe for ten pounds each: but from the cuſtom of the deer and commoners cattle being ſuffered to depaſture thereon without limit, the young timber is totally deſtroyed, and the underwood much damaged[r].

Cambridgeshire.

The quantity of timber growing in this county is ſmall, except in the pariſhes adjoining to Eſſex and Suffolk on the ſouth-eaſt, and to Hertfordſhire and Bedfordſhire on the ſouth-weſt.

In one pariſh three thouſand trees were bought in 1791 for the dock-yards, and no likelihood of any ſupply for them. And in many Woods great timber trees have been cut down to encourage the growth of underwood, both on account of the increaſed price and quick return. Few incloſures of commons have taken place, but if they ſhould, ſo little encouragement is given for raiſing Oak timber, that there is little probability of much being planted[s]. Lately many pariſhes have been incloſed, and ſome plantations of mixed trees have been made near Cambridge.

Chester.

Timber diminiſhed, but perhaps leſs in Woods than in other places. The improvement of roads and canals has occaſioned much timber to be carried to the dock-yards; but this county is not deſtitute of it in any parts where timber thrives well. The conſumption of Oak timber for building, &c. is diminiſhed, principally on account of the large importation of Deal timber at Liverpool, which is carried to moſt parts of this county, at a ſmall expenſe, by canals. There are few underwoods. Oak is ſtill much planted, and often with other trees, which are frequently cut out to make room for the Oaks[t]. There is abundance of Oak in the hedge-rows, particularly on the Lancaſhire ſide, to a degree which is frequently detrimental to the farms. Some gentlemen of large property have paid great attention to planting, and have conſiderable plantations of young thriving timber upon their eſtates, but quick-growing or ornamental trees have been chiefly planted, and the Oak has been too much neglected[u].

Delamere Foreſt is a large tract of land entirely bare of Wood, and apparently not very favourable to the growth of it. Nicholas Aſhton, however, of Woolton hall, near Liverpool, in 1795 planted 133 acres of waſte moor land adjoining to the foreſt, with 487,049 trees, of which 16,200 were Oaks; 4,800 Aſh; 18,060 Beech; 7,200 Elm; 242,600 Scotch Fir; 181,200 Larch; 600 Alder; 15,000 Sycamore; and 1,200 Willow.

Cornwall.

Hedges in general do not abound with timber in this county; the growth of it any where is very partial, and the county by no means abounds with timber fit for naval uſes. What plantations have been made are for the ornament of gentlemens' ſeats. There are few commonable Woods, and what there are belong to the dutchy of Cornwall. Coppices that ſold forty years ago from 5l. to 10l. the acre, now bring from 12l. to 18l.

At Trevetho, Mr. Praed has taken much pains to raiſe plantations, where they are expoſed both to S. W. and N. winds. He plants the Pinaſter, which though not a valuable Wood, nor of a beautiful form, he has found to ſtand the ſea air ſurpriſingly. He places it on the higheſt parts, and very thick in the outer rows of his plantations; and within he plants Oak, Aſh, Elm, Plane, &c. He ſometimes alſo makes large groves entirely of Pinaſter, and when they are grown to the height of twelve or fifteen feet, he cuts down the inner ones, and plants foreſt trees of large growth. He has found that ſowing the ſeed of the Pinaſter in ſpring does not anſwer; he therefore ſows them in june, when the cones naturally drop their ſeeds.

Sir John St. Aubyn has alſo planted ninety-three acres with a great variety of Foreſt trees at Clowance, where there is alſo a great quantity of fine old trees, planted by his father and grandfather, who introduced the beautiful eaſtern Plane into the county, and which is here of a very large ſize. Sir John has alſo planted the Pinaſter at St. Michael's mount, and it flouriſhes well, although expoſed in winter even to the ſpray of the ſea. At Godolphin there is a very ancient plantation near the houſe, and indeed there are others in ſo many places, that it is obvious it is not owing either to ſoil or climate, that there are ſo few trees in Cornwall[x].

Cumberland.

This county is far from being well wooded. The banks of the river Caldew have the largeſt proportion of old Oak timber. It does not ſeem to be ſuffered to attain a ſufficient age for the purpoſes of ſhip-building. A Wood near Weſt Ward was felling (in 1794) of more than two hundred acres, that was little more than thirty years old; the whole was cut away, without leaving any to ſtand.

Lately many plantations have been made near gentlemens' ſeats, which ſhow, by their vigorous growth, how well adapted the greateſt part of this county is for the production of Wood. Lord Muncaſter's extenſive and thriving plantations near Ravenglaſs, ſhow that the country along the coaſt need not be naked[y]. Mr. Thomas Gaitſkill, of Little Braithwait, planted in 1791, on fifteen acres, 43,300 Larches.

Derbyshire.

Large Oak timber greatly diminiſhed, and not much now left, either in Woods or hedge-rows, the grubbing of which is common. In the few Woods which remain, called Spring Woods, the fall is from eighteen to twenty years growth; upon every acre are then left a certain number of trees ſixty, forty and twenty years old, a proportion of which is cut every fall. But the prevalent idea is, that it anſwers better to cut down the young Wood for country uſes, than to let it grow into timber. Though a very large quantity of Deal is brought in by canals, ſcarcely any Oak timber is ſuppoſed to be carried out; partly owing to the ſcarcity of it, partly to the demand, in preference to deal, in that part of the county where limeſtone is the only material for building. The price of Oak timber has doubled within forty years, owing to the decreaſe of Woods, and the alteration in the mode of farming, from ſheep-walks to dairy and tillage, which require large expenſive buildings, in which Oak only, and ſome of a large ſcantling, muſt be uſed; any other Wood but that decaying quickly, on account of the porous damp quality of the limeſtone[z].

Little or no land is newly planted, except for ornament. Much Oak was formerly growing in almoſt every pariſh, where there are large fields called ſtill the

Wood. The county hall at Derby was built with ſixty-three large Oaks from Foſton Woods, where there now remains only the appearance of a Wood having once grown there. Beech, Elm, Aſh, Sycamore, Larch, and different ſorts of Firs and Pines are now chiefly planted, and are preferred to Oak, from their quick growth. There are extenſive commons, but no timber on them: and thoſe in the northern parts, which include the greateſt part, are improper for Oak [a].

Devonshire.

Woods diminiſhed. Much Oak in the hedges, and might be more if care were taken to mark the ſaplings before the hedge-wood is felled, and tenants were reſtrained from lopping maiden trees. Very little Coppice Wood; but the young ſaplings are generally left at the firſt fall, and cut down at the ſecond. The improvement of roads has brought timber dealers into the more inland parts, and by that means large ſupplies have been ſent to the dock-yards; but they will not be able to continue the ſupply. Many woodlands have been converted to tillage; but no plantations of any extent have been newly made. The commons are very extenſive, but there is no timber on them. Many of them, if incloſed, would produce good timber [b].

Dartmoor, though denominated a Foreſt, has little or no Wood. The only natural one is Wiſtman's Wood near Crockern Torr, the ſeat of the parliament of the Stannaries. It conſiſts of huge decayed ſtumps of trees amidſt looſe rocks of granite: on their decayed tops thorns, brambles, &c. are ſhooting forth, forming altogether a moſt groteſque appearance.

Mr. Juſtice Buller planted about forty thouſand trees, Larch and Firs intermixed with other trees, but they have almoſt wholly periſhed [b].

Dorsetshire.

Though this county is extremely barren in timber and wood, there are many ſpots appropriated to the growth of underwood. The ſoil is chiefly cold and wet, and the underwood, cut at ten or twelve years growth, produces five or ſix pound an acre for faggots. As to Oak timber, there is ſome about lord Digby's at Sherburne caſtle, lord Ilcheſter's at Milbury, on that part of the vale of Blackmoor in Mr. Sturt's poſſeſſion about Bethſcombe, and in a few other ſpots; but even there the quantity is trifling, as a national conſideration. Many noblemen and gentlemen have made plantations about their places of reſidence, with great taſte and judgment, among which Mr. Portman's bank at Blandford is a moſt beautiful object. The earl of Dorcheſter's at Milton, and Mr. Frampton's at Morton, are both conſiderable. If large tracts on the tops of the higheſt hills and pooreſt lands, were incloſed and protected from game, and either ſown with a mixture of ſeeds of different foreſt trees, or planted with ſeedlings, not above two years old, they would in a few years become beautiful to the eye, and profitable to the owner. But moſt attempts of this kind have been upon too ſmall a ſcale, and no ſooner have the weſterly winds from the coaſt attacked them, than they become miſerable and unthrifty: they have alſo been planted from nurſeries, and of too large a ſize. The ſoil on the tops of the hills is well adapted to Beech, and Oak would not fail to grow, provided there was a ſufficient mixture of Firs to ſhelter them in their infancy [c].

Durham.

In this county, the banks of the rivers and brooks, in ſome places, particularly in the neighbourhood of Durham, are fringed with Wood of conſiderable growth and value; but the reſt of the country is for the moſt part naked. In an act of parliament obtained in 1773, for incloſing upwards of 18,000 acres of waſte land in the pariſh of Lancheſter, there was a clauſe to entitle the copyholders and leſſees under the biſhop of Durham to diſpoſe of the woods, underwoods and trees growing or to be planted on their allotments. In conſequence of this clauſe, ſome thouſands of acres have been covered with trees, which are thriving wonderfully on ground incapable of any other improvement. Thomas White, Eſq. of Weſt Retford, in Nottinghamſhire, purchaſed 227 A. 3 R. 24 P. for 260l; beſides 300 acres, part of the ſaid common; both freehold and tithe free [d]; and has planted in 1787; 50,000 Oaks, 35 acres with Aſh, 100,000 Scotch Firs, 15,000 Spruce Firs, 3000 Silver Firs, 13,000 Larches, two acres two roods with the occidental Plane, 10,400 Lombardy Poplars, 37,230 Alders, on thirty-one acres four perches; in 1784, 7000 Norfolk Willows [e]. Mr. White's example has been followed by many others, whoſe young Woods promiſe equal ſucceſs.

The great demand of ſmall-ſized Wood for the collieries, induces the early felling of timber; and it is too general a practice to cut down all that will turn to profit, leaving the roots to ſhoot afreſh. Much Oak has been carried to Stockton, Sunderland and Newcaſtle, for building the ſhips uſed at theſe ports. Fir timber, imported there, is chiefly uſed in building houſes. No great quantity of woodland has been converted to tillage. Many gentlemen have made extenſive plantations, in which a conſiderable quantity of Oak has been planted. It is too much the practice to plant Aſh in new hedges; but Oak ſeems well ſuited to the ſoil, as it grows very well in all parts [f].

Essex.

The Woodlands are extenſive, and would ſupply a vaſt quantity of well-grown ſtraight timber, could the proprietors be induced to ſuffer the trees to ſtand till they arrive at their full ſize; but the very diſtant proſpect of ſeeing young trees become fit for the dock-yards, the late high price of bark, and the injury they are to the underwood, which is felled every twelve, fourteen or ſixteen years, together with the increaſe of rent, preclude all hopes of keeping up a ſtock of timber, and even ſeem to threaten the deſtruction of moſt of the Woods, which are yearly leſſened to convert the lands into farms [g].

The land in Birdbrook pariſh is particularly favourable to the growth of Oak; there are ſeveral fine ſtandards in the paſtures, one of which, at five feet from the ground, meaſures eleven feet nine inches in circumference. In Baythorne Hall garden is a clump of Alders, the largeſt of which, at five feet from the ground, is ſeven feet four inches in circumference, and has from thirty to thirty-five feet in height of clear timber.

Hatfield Broad-Oak, or Takely Foreſt, is about one-half (500 acres) covered with Wood, among which, with much other valuable timber, is an Oak, that meaſures at five feet from the ground, fourteen feet in circumference, and is thought will cut to timber at ninety feet from the ground. The clear rich lands of Woodſide green, and every other part of the Foreſt, which is not uſefully employed in the growth of timber, might be materially improved, either by cultivation, or for encouraging the growth of Oak.

The great Foreſts of Epping and Henhault are an intolerable nuiſance to the farmers, on account of the depredations, committed on their crops, by the deer; and being ſo near the metropolis are the nurſery and reſort of the profligate. There is little timber in theſe Foreſts, and the dodders and underwood are of ſmall value in compariſon to what they would be if this tract of country was incloſed. Mr. Vancouver gueſſes that there may be 10,000 acres in theſe Foreſts not producing or being favourable to the growth of Oak or other valuable timber, at preſent eſtimated to produce 5 s. 8 ½ d. per acre, which by incloſure might be eaſily increaſed to 20s. On that part of the Foreſt, within the pariſh of Epping, conſiſting of 527 acres, the lord of the manor has, by grants from the crown, the excluſive right of all timber, underwood and buſhes. The land is well adapted in general to the growth of Wood, particularly Oak, which by the judicious management of the preſent poſſeſſor, is in a very flouriſhing ſtate.

In Stifted are numerous Woods, though gradually leſſened; when well attended to, the underwood produces, for hop-poles, at twelve or fourteen years growth, from 7s. to 10s. an acre per annum, and in ſome places 14s. The timber in them is in general a prejudice. It is far from growing large, forty feet, a well-grown old tree, top and bark included, the buyer falling, ſells at 2s. a foot.

At Widdington the Woods are ſmall, but well attended to: they are cut at twelve years growth, and worth at the ſtub about 8l. an acre: they conſiſt of Aſh, Sallow, Hornbeam, Hazel and Thorn.

The neighbourhood of Boreham is plentifully wooded. The Woods are cut at fifteen, ſixteen and ſeventeen years growth, and are more or leſs valuable, according to the quantity of hop-poles they produce, that being the chief article worth attention, as fire-wood is cheap: for which reaſon conſiderable portions of woodland are cleared annually, and brought under the plough.

At Dunmow the proportion of woodland is ſcarcely a fifteenth part of the whole. The underwood is uſually felled at fourteen or fifteen years growth, and the annual rent is from 10s. to 14s. or 15s. an acre [h].

Lewis Majendie, Eſq. of Caſtle Hedingham, planted there in 1786, 5,300 Oaks; in 1790, 1,900 Aſhes; again in 1793, 1,900 Aſhes on ſeven acres nine perches; in 1792 and 1793, 29,700 Spaniſh Cheſtnuts, on ten acres three roods and five perches [i].

Richard Muilman Trench Chiſwell, Eſq. planted at Debden-hall 10,579 Elms, and 11,000 Lombardy Poplars.

Gloucestershire.

Woodlands, chiefly Beech, decreaſe very much, and have doubled the price within twenty years. Plantations are much to be wiſhed for, not only for future ſupply, but becauſe bleak ſituations are very much improved by the ſhelter they afford.

Coppices are much wanted. They are chiefly compoſed of Aſh; the produce is fetched from a great diſtance for coopers, &c. and has riſen greatly in price. The chief woodlands are in the pariſhes of Chedworth, Withington and Dowdeſwell; ſmaller patches in Guiting and one or two neighbouring pariſhes: they are cut at about eighteen years growth, and produce from 30l. to 60l. per acre. There are ſome modern Coppices in the pariſhes of Wick and Slaughter, which produce from 25l. to 60l. per acre. Alder Coppices are cut at twelve years growth, and are worth from 15l. to 25l. per acre [k].

The trees planted in new incloſures, more than make amends for the old fences that have been grubbed. Very little woodland has been converted to tillage, and ſtill leſs planted. No plantations of Oak have been made lately, except in the foreſt of Dean: and theſe have been broken into by lawleſs perſons in many places. Perquiſites of office, extremely lucrative to ſurveyors and keepers, are by no means advantageous to his majeſty's rights.

On the Cotſwold hills are conſiderable tracts of cover, belonging principally to lord Chedworth, lord Bathurſt, and the biſhop of Worceſter; but very little timber in them fit for the navy, and no water-carriage near except lord Bathurſt's, whoſe Woods are chiefly Beech [l].

Hampshire.

Many parts of this county are well wooded, but there are immenſe tracts of open heath capable of improvement by cultivation or planting. On the north ſide towards Berkſhire the land is deep, and produces conſiderable quantities of Oak and Elm; in many places the Oak has been tranſplanted, yet is arrived to fine timber. Towards Rumſey the country is interſperſed with Woods and hedge-row timber. Between that and Ringwood is a conſiderable part of the New Foreſt.

This Foreſt now extends from Godſhill N. W. to the ſea S. E. about twenty miles; and from Hardley E. to Ringwood W. about fifteen miles. It contains about 92,365 acres, of which 24,797 are private property, 625 copyhold of the manor of Lyndhurſt, 1,004 acres leaſehold under the crown, 902 encroachments, 1,193 held by maſter-keepers and groom-keepers attached to their reſpective lodges, and the remaining 63,844 acres are the Woods and waſte lands of the foreſt.

The intereſts of all the inferior officers ſo claſh with that of the Foreſt, that it is in vain to expect either a preſervation of the timber now growing, or an increaſe from new plantations, whilſt the preſent ſyſtem remains, of their emoluments being derived from deer, ſale of browze wood, rabbets, and ſwine. All theſe concur in the deſtruction of young timber, and unleſs ſome means are taken to prevent theſe and other abuſes, in a few years there will be no timber worth mentioning left upon the Foreſt.

It appears from actual ſurveys how much the timber has decreaſed, and what the Foreſt was formerly capable of producing.

		No. of trees.	No. of loads.	Total loads.
1608.	Timber fit for the navy	123,927	197,405	315,477
	Dotard and decayed trees - -		118,072	
1707.	Timber fit for the navy -	12,476	19,873	19,873
	Dotard trees not ſtated.			
1764.	Timber fit for the navy -	19,836	33,662	40,497
	Defective Oaks - -	1,743	3,835	
1783.	Timber fit for the navy -	12,447	19,827	20,830
	Defective Oaks - -	596	1,003	

From other accounts it appears that the navy has been ſupplied with about 885 loads of Oak timber yearly, for the laſt twenty years.

The crown has a right, by an act of William III. to keep 6000 acres conſtantly incloſed, for the growth of timber.

Alice Holt and Woolmer Foreſt is ſituated in the eaſt part of the county, on the borders of Surry and Suſſex. It contains about 15,493 acres, about 6,799 of which are private property. On 2,744 acres of crown lands in Alice Holt, according to a late valuation, there is growing about 60,000 pounds worth of timber. Upon Woolmer there is no timber worth mentioning. In 1608 there was a ſurvey of the timber, when there were found growing in the foreſt 1,301 Oak trees fit for the navy, and 23,934 loads of defective trees: and from a ſurvey in 1783 it appears that there remained only about 15,142 loads, including defective trees; and thoſe generally of one age, namely from 100 to 120 years growth; and that there are ſcarcely any to ſucceed them.

The foreſt of Bere is in the S. E. part of the county, on the north ſide of Portſdown, and within eight miles of Portſmouth. It contains about ſixteen thouſand acres, of which one third is incloſed, and the reſt is open foreſt land; the ſoil is good, and proper for the growth of Oak timber.

There was a ſurvey in 1608, and another in 1783, from which it appears that the timber in the latter was only a twenty-eighth part of what was growing at the former.

In the Iſle of Wight timber was formerly plentiful, but the proprietors have had ſo good a market for it at Portſmouth and other dock-yards, that little now remains. No young trees have been planted to ſupply the place of the old ones, ſo that in a few years the iſland will be entirely robbed of its timber.

Parkhurſt or Cariſbrook Foreſt, lying in the centre of the iſland, is the property of the crown. It contains thirty thouſand acres, and has long been without a tree of any value. The ſoil is in many places extremely good: ſeveral large ſpots are to be found on which the Oak would thrive well, and none are ſo bad as to preclude the hope of the Larch and Scotch Fir ſucceeding on them [m].

The quantity of timber has been greatly diminiſhed within the laſt forty years: before which there was enough to build fifty ſail of the line, without going into the New Foreſt. But now by the amazing conſumption in his majeſty's dock-yards, by the great demands for Eaſt India ſhips, by the general practice of grubbing up hedge-rows, and by not encouraging the growth of young ſaplings, it is ſo diminiſhed, that it would be difficult to find a frame for a ſeventy-four gun ſhip, and as to a firſt, ſecond, or third rate, there is no ſuch timber left, except in the New Foreſt, and very little there;

there: What plantations have been made are of Fir more than Oak [n].

Herefordshire.

The river and brooks may be traced by the Wood on their banks. There is much valuable timber, moſt of it in hedge-rows; but this is greatly injured by lopping. Coppice Wood is kept under a regular ſyſtem: the ſofter Woods are cut from twelve to fourteen years, and the Oak from eighteen to twenty years growth. One ſtandard is left to each forty-nine ſquare yards; theſe are maiden trees, and left clear of incumbrance [o].

In the eleventh report of the commiſſioners of the land revenue (app. n. 11.) it is ſaid that large Oak timber is diminiſhed very much indeed; that the growth of Oak in hedge-rows is not much encouraged, that the trees are much ſtripped and lopped by the farmers, and that the principal timber for the navy now remaining is in Woods; that ſaplings are left ſome of which are cut at the ſecond fall, and others left for timber; that a very conſiderable ſupply of timber has been ſent to the dock-yards within the laſt twenty years (ſince 1772), and that parts of the county are ſo ſtripped that even common building timber is ſcarce, ſo that brick and ſtone is now employed inſtead of ſtuds; whereas forty years ago timber was a mere drug. The value of underwood is much increaſed ſince the introduction of hops; and a much larger quantity of land is converted into tillage than has been planted. No plantations indeed of any extent have been made. Variety of trees have been planted for ornament, but few of them are likely to be of ſervice to the navy. The county in general is very much incloſed. Commons of any extent are on the hills, on which no doubt trees would grow well.

Many thouſand Oaks have been planted by the truſtees of Guy's Hoſpital, on their eſtates.

Hertfordshire.

The quantity of Oak timber fit for the navy is greatly decreaſed in this county. Few Woods have any large timber in them: what there are of large ſize are chiefly in hedge-rows, and many of theſe have been grubbed up to increaſe the land in tillage. In Woods that are in the hands of occupiers few ſaplings are left; but if in owners hands, a proper ſucceſſion of timber may be found. It is however moſtly conſumed within the county for barn-floors, paling, railing, poſts, gates, &c. and many Woods have been ſtocked or grubbed up. In Woods lately planted, Firs and Poplars have been preferred to Oak and Elm, on account of their quick growth. There are few commons, and on them little or no timber. On newly incloſed fields little attention has been paid to raiſing Wood. Several thouſand acres of land in this county would anſwer better if planted with Oak, Aſh, Elm or Beech, than in tillage [p].

John Hunter, Eſq. of Gubbins, in the pariſh of North Mims, planted 40,000 Oaks on twenty-ſeven acres, in the year 1799 [q].

Huntingdonshire.

Oak timber is not much raiſed in this county, and there is very little fit for the navy; being uſually cut down when it begins to be moſt valuable for that purpoſe. Underwood is not carefully ſelected and planted. Both that and timber might frequently be planted with good ſucceſs on land of very low quality for tillage [r]. Much however has been cut down, and very little planted in its ſtead.

Kent.

The chief of the woodlands of Eaſt Kent are diſperſed between the great road from Rocheſter to Dover, and the chalk-hill that runs from Folkſtone by Charing to Detling. Theſe Woods furniſh the country with firewood, tillers for huſbandry uſes, and the dock-yards with timber; but the moſt material part of their produce, is the immenſe quantity of hop-poles.

[n] Eleventh Report.
[o] County Report.
[p] Eleventh Report, app. n. 11.
[q] Tranſ. Arts.
[r] County Report.

The Weald was in ancient times an immenſe foreſt, but is now for the moſt part cleared and converted to tillage and paſtures. There are however ſome woodlands in their original ſtate.

On a ſurvey of the Woods through the whole county, it appears that there are about 13,290 acres, of which 1000 are waſte lands on Burham downs, free from november to march. Of the remainder, 400 acres in Stalisfield belong to the Hon. Mr. Watſon, and have been improved by planting Aſh, Cheſtnuts and Willow; 350 acres in Newenden belong to Sir Edward Knatchbull; 140 acres in Bickner and Hucking are the property of Mr. Chambers; 300 acres in Newington and Milton, 180 in Thurnham, 400 in Rainham and Newington, belong to the Earl of Aylesford; 350 in Thurnham and Stockbury, 200 in Detling and Thurnham, 500 in Chatham, 300 in Aylesford and Boxley, 50 in Boxley, belong to Mr. Beſt; 200 acres in Stockbury belong to Meſſrs. Head and Roper; 180 acres in Detling, and 300 acres in Chatham, belong to Mr. Foote; 200 acres in Aylesford and Boxley belong to Meſſrs. Read, Seager and others; 1000 acres in St. Margaret's belong to the wardens of Rocheſter bridge; 500 acres in Shawſtead and Gillingham belong to the dean and chapter of Rocheſter; 1,500 acres in Langley, Leeds, Sutton, &c. are the property of Mrs. Bouverie, Sir John Filmer, and others; 500 acres in Peckham and Mereworth, belong to Mrs. Bouverie, Sir William Twiſden and lord le Deſpencer; 600 acres in Peckham and Ofham belong to lord Le Deſpencer and William Geary, Eſq; 160 acres in Maidſtone belong to lord Romney, and 300 acres in Barming and Ayleford belong to lord Romney and Meſſrs. Amherſts; 80 acres in Yaldon and Hunton belong to Mr. John Miller; 600 acres in Feſton and Eaſt Malling belong to C. Milner, Eſq. and the Hon. Mr. Puſey; and 3000 acres in Goudhurſt, Cranbrook, Ticehurſt, &c. belong to Mr. Cartier and others. Theſe Woods produce ſome timber, hop-poles, cord-wood, fencing poles, ſtakes, ethers, hurdles, bavins for bakers and burning lime.

The Oaks are all cut in the flaying ſeaſon, for the bark of all ſizes. The fencing-poles are either uſed whole, or cut into gates for ſheep. The hop-poles are ſorted into three, four or five ſorts, and ſold by the hundred. The faggots or bavins are made into lengths of five feet, the beſt for bakers and houſekeepers, and on the hills they make inferior ſorts, called kiln-bruſh for burning lime. Stakes and ethers are cut out before the faggots are made. In the neighbourhood of Chatham they cut ſome ſmall bundles of bruſh and cord-wood, for the uſe of ſhipping and the metropolis [s].

Mr. David Day, of Frindſbury, planted ſixteen acres with Aſh; and afterwards ſeven acres and nine perches with 63,000 plants more.

Henry Godfrey Fauſſet, Eſq. of Lower Hardreſs, planted eight acres with 7,712 Aſh trees, in 1790.

Mr. Joſeph Mace, of Aſhford in Biddenden, planted 3000 Cheſtnut trees on ſix acres ſeventeen perches.

William Pattenſon, Eſq. of Ibornden in Biddenden, in 1785 planted a quarter of an acre; and in 1789 ſeven acres and a half, containing about 13,500 plants, of the red or upland Willow. There are ſeveral other plantations of it in that neighbourhood.

Lancashire.

Towards the middle of the county there are ſome good Woods; there is alſo a conſiderable quantity grown in hedge-rows; but as ſunſhine is generally preferred to ſhade, timber wood ſeems on the decline. In the northern part there are many acres of coppices, which are cut down every fifteen years, and burned into charcoal. There are many excellent plantations about gentlemens' ſeats, well attended to, and in a thriving ſtate. Towards the coaſt it is with great difficulty that Woods of any kind can be raiſed; yet near the ſhore at Fornſby hall, the Rev. Mr. Fornſby, has planted ſeveral acres with foreſt trees, which are in a flouriſhing ſtate. They were originally planted when very ſmall, in holes, four inches below the ſurface, and

[s] County Report, 8vo edit. 1796.

were

Digitized by Google

were ſheltered from the winds by ſods raiſed round them, till they had taken firm root. A mixture of ſea-ſlutch, rich earth and moſs was put beneath their roots. The Scotch Fir, Sycamore, Platanus or Plane, and the Aſh, ſeem moſt congenial to the ſoil, which is ſandy, and are leaſt injured by the inclemency of the climate.

The Alder is in great demand for poles to hang cotton yarn on to dry, and for the bark which ſells to the dyers at nearly one penny per pound. Alders planted on the ſide of the duke of Bridgwater's canal, to ſecure the banks, where the ſoil is of a looſe texture, have not only anſwered that purpoſe, but have proved a profitable plantation: they may be cut down every fourth or fifth year [t].

Fewer Oaks have been planted of late years than other trees. Incloſures have not increaſed the growth of timber [u].

Charles Gibſon, Eſq. Quermore Park near Lancaſter, planted in 1798 and 1799, 7,500 Oaks, 1000 Aſhes, 6,500 Beeches, 5000 Birches, 500 Cheſtnuts, 500 Horſe-Cheſtnuts, 8000 Elms, 2000 Scotch Firs, 2000 Spruce Firs, 7,500 Larches, 2000 mountain Aſhes, 7000 Sycamores.

Thomas Rawlinſon, Eſq. at Yealand, planted in 1791 and 1792, 18,910 Oaks, 20,170 Aſhes, 2,300 Beeches, 3,940 Birches, and 705 weeping Birches, 3,900 Elms, 3,650 Scotch Firs, 2,010 Spruce Firs, 2,900 Larches, 2,310 Sycamores, 300 Huntingdon Willows; in all 62,190 trees.

The Rev. Thomas Dunham Whitaker, at Holme in Whalley, planted in 1790 and 1791, 64,135 Larches [x].

Leicestershire.

There is very little timber in this county except in the hedge-rows. Burbach Wood contains about ſixty acres, with many thouſands of young thriving Oaks. Aſton Flamvile Wood, about the ſame ſize, has ſome fine young Oaks and ſmall Aſh. Theſe, and the Woods near Beaumanor, are the principal.

At Cleybrook and all that part of the county, there is much timber in the hedge-rows; but on the Melton-Mowbray ſide there is very little. They have a few coppices which are cut at about twenty years growth.

Charnwood Foreſt contains 15 or 16,000 acres. The hills might probably be planted to advantage, although they are bare of ſoil and full of rocks; ſince the Woods near Beaumanor, on the edge of the foreſt, are found to thrive very well [y].

Lincolnshire.

The Woods in the ſouth part of this county produce Oak, Aſh and Poplar.

Sir Cecil Wray's plantations, made between 1760 and 1794, conſiſt of 260 acres; principally Scotch Firs. At the beginning he alſo planted Oaks, Aſhes, Beeches, Elms, Silver Firs, Spruce Firs and Larch. The Larch, Oak, Aſh and Beech made no little progreſs during the firſt three years, and the Scotch Fir got on ſo well, that for the enſuing ten years he planted ſcarcely any other ſort. The Silver Fir grew very well, but it is ſaid will be ſhort-lived. The Spruce Fir alſo grows well and large. Having reaſon to think better of Larches, he recommenced planting them fifteen or ſixteen years ago; and now has about fifty-three acres of them growing completely well, and from the value of the Wood, promiſe to pay twice as well, at leaſt, as the Scotch Firs.

About Norton-place Mr. Harriſon has formed a large range of beautiful plantations, which ſurround and break his lawn, except where it opens to the wolds. In twenty-two years theſe have flouriſhed ſo rapidly that he has cut Larch of a conſiderable ſize, and has incloſed eight hundred acres from the thinnings.

But of all the planters in the county, lord Yarborough takes the lead: for ten years paſt he has planted 100 acres yearly, and is continuing it; but deſigns ſoon to leſſen it, the lands he had aſſigned for that purpoſe being nearly covered.

[t] County Report, 8vo. ed. 1795. p. 84.
[u] Eleventh Report, app. n. 11. [x] Tranſ. arts.
[y] County Report, qu. 1794.

Sir Joſeph Banks's Woods have been very carefully managed ſince 1727, in a rotation of twenty-three years. Full-grown Oak-timber is taken out in the proportion of one-fourth, in Woods of the beſt quality, and of one-fifth upon inferior land. Willow, Sallow, Alder, Hazel and other bruſh are cut clean. Full-grown Aſh, Elm, &c. are cut, leaving a proportion of the beſt for the next crop; that is, ſuch as will pay for a ſecond growth of twenty-three years. Very little of the Oak has five growths, or 115 years; in general it has four growths, or ninety-two years. The produce of an acre on an average is 45l. for timber, bark, poles and bruſh. The Woods cover 805 acres.

The duke of Ancaſter has four or five hundred acres of woodland, which he cuts at eighteen years growth. The marquis of Exeter has very extenſive Woods about Bourne, &c.

Sir Cecil Wray has made ſome valuable obſervations, derived from extenſive experience.—He would always plant each ſort of tree by itſelf; at leaſt he would never plant Scotch Firs intermixed with others, as nurſes; for from their ſpreading branches, they ſoon become bad neighbours. They may be of ſervice however on the outſide of plantations, as a ſhelter where they are expoſed.—He would never plant a tree older than two year ſeedlings.—He would never put more than 2000 trees on an acre, and he thinks 1,200 fully ſufficient.—He would always trim off the ſide branches, when they are ſo ſmall as to be cut with a knife; in which caſe the wound will grow over.—Scotch Firs are valuable as growing faſt, as affording Wood of many uſes in country work, as ſupplying the poor with fuel from the cones and rotten branches, as keeping deer and ſheep in winter, particularly in ſnows, with the green boughs, and as firewood, fencings, &c. &c [z].

Middlesex.

The Woods and Coppices in this county have been decreaſing for ages, and will probably in time be annihilated. There are however ſtill a few acres ſo occupied on the north ſlopes of Hampſtead and Highgate hills; about 100 acres on the eaſt ſide of Finchley common; and about 2000 acres on the N. W. ſide of Riſlip, together with about 3,000 acres, the remains of Enfield chaſe. Rather more than half this quantity is Wood pretty well ſtocked with thriving young Oaks; the reſt is coppice [a].

Monmouthshire.

This county is well wooded, and there are many coppice Woods, which are cut from eleven to fourteen years growth. Much fine Oak timber is growing upon Tredegar and other eſtates [b]. The Woods, coppices, and plantations of Perſefield are well known.

Benjamin Waddington, Eſq. of Lanover houſe near Abergavenny, ſince 1799 planted twelve acres with Larches and other trees, and intends planting near fifty acres more with Larches.

From the eleventh report of the Commiſſioners of the Land Revenue it appears, that timber is decreaſed, that hedge-rows are commonly grubbed up, that greater quantities of timber have been felled than the county will be able to ſupply, that it is the practice to fell them for the ſake of the underwood, and that plantations lately made, have been of ſuch trees as are not fit for naval purpoſes.

Norfolk.

This is not a woodland county. Foxley Wood, belonging to Sir John Lombe, Bart. which is 309 acres, is perhaps the largeſt. There are other conſiderable Woods in Aſhwell Thorpe, Hetherſet, Ketteringham, Hethel, Bunwell, Hempnall and Shottiſham, of 800 or 1000 acres in the whole, beſides ſeveral other ſmaller Woods in other parts.

Modern plantations for ornament have kept pace with moſt other counties. Great bodies of Firs, intermixed with a leſs number of foreſt trees, have been

[z] County Report, 8vo. ed. 1799.
[a] County Report, 8vo. ed. 1798. [b] County Report.

Digitized by Google

planted in parks and home grounds; but pits, corners, and ſcreens or belts have been little attended to.

Mr. Marſham of Stratton ranks firſt in priority. He might ſell ſome of the trees which he planted with his own hand for ſix or ſeven pounds each; and he has a Cheſtnut, which he ſet a nut, and afterwards tranſplanted into a poor ſandy ſoil, which runs timber fifty-eight feet, and ſquares upwards of twenty-two inches at the butt, ſo that it muſt at leaſt have eighty cubical feet of timber.

Mr. Berney of Bracon ranks next as a planter in point of date, having paid great attention to planting upwards of fifty years. In 1757 he had a ſilver medal for a large plantation of Oaks. His Cheſtnuts are very fine, many of them fourteen or fifteen inches girth, and his Larch as much: he has put the latter to almoſt all purpoſes of building, and to many cabinet uſes. He entertains the higheſt opinion of Larch Wood, and recommends it to be felled as all Firs ſhould be, in july or auguſt. But this is probably an erroneous practice.

Among modern planters, in point of quantity Mr. Coke ranks foremoſt. He has planted 480 acres, in which two-thirds of the plants are intended to be thinned out and cut down for underwood, ſo as to leave Oak, Cheſtnut and Beech only as timber. His intention is to continue planting fifty acres every year, till he has completely environed 3000 acres, which is to compoſe his park and demeſne farm.

Mr. Windham of Felbrigg is alſo a conſiderable planter. His plantations are deſigned to ornament and belt round his park, and to extend his great woodland ſcene nearer the ſea, towards which, at two miles diſtance, it forms a grand bulwark. Moſt of them have been raiſed from ſeed. One was ſown with Acorns, Cheſtnut and Beech-maſt, ſeventeen years ſince: it has been already twice thinned for hurdle Wood: the trees are moſtly thirty feet high, at regular diſtances of twelve feet, with a valuable underwood at four feet diſtance.

A belt ſixty-ſix yards wide and nine miles round, incloſes the eſtate of Mr. Galway of Toſts near Thetford. It was planted by Mr. Nelſon with a variety of trees, at ſix feet apart between 1770 and 1778.

Lord Petre's park, in the midſt of a barren dreary country, forms an agreeable ſhady retreat, covered with a pleaſant verdure, and richly ornamented with foreſt trees of large dimenſions: his Lordſhip is now conſiderably extending his plantations, to the open parts which lie on the outſide of his eſtate.

Sir William Jerningham's plantations at Coſteſey, four miles from Norwich, are large and flouriſhing, and have been made with much judgment and taſte.

The plantations upon the eſtate of Miſs Norris, at Witton, are made quite in the face of the German ocean. Having been planted very thick they have ſo flouriſhed, without any old trees to ſhelter them, that in the courſe of twenty-two years they have changed a conſiderable tract of naked land into an impervious woodland ſcene, in one of the moſt cold and expoſed ſituations in the kingdom [c].

John Morſe, Eſq, of Sprowſton, ſet twenty-five acres with acorns, in october 1788 and march 1789.

George Nelthorpe, Eſq. planted 35,000 Alders on twelve acres, at Linford, in 1794.

James Denton, Eſq. of Feltwell, ſet thirty-eight acres with acorns, in 1794.

Lord Viſcount Townſend planted 463 acres at Rainham, chiefly with Scotch Firs [d].

Northamptonshire.

There are ſeveral very extenſive tracts of woodland in this county, conſiſting of foreſts, chaſes, and purlieu Woods. The moſt conſiderable foreſt is that of Rockingham, in the northern part, beginning near Wanſford, and extending near twenty miles towards the centre of the county. Whittlebury and Salcey are two other extenſive foreſts, lying towards the S. The chaſes are thoſe of Geddington and Yardly; the former in the neighbourhood of Rockingham foreſt and the latter in that of Salcey foreſt. The purlieu Woods are both extenſive and numerous, particularly towards the lower parts of the county, and upon the borders of Rockingham foreſt. Beſides theſe, there are ſeveral ſmall tracts of woodland, very advantageouſly and ornamentally ſituated, in many other parts of the county.

The underwood in the foreſts and chaſes conſiſts principally of black and white Thorn, Aſh, Sallow, Maple, and ſome Hazle. It is generally cut at from twelve to eighteen years growth. The proprietors are empowered to fence in each part as ſoon as it is cut, for four years from deer, and for ſeven years from the commoner's cattle. The depredations of theſe and of the people occaſion this underwood to be worth only about four pounds an acre on an average. It is ſold ſtanding, and the purchaſers cut and carry it at their own expenſe. It is moſtly uſed for hurdles or firewood.

A fall of Oak timber is generally made in that part where the underwood is cut. This conſiſts either of the moſt unimproving trees, or ſuch as are of a large ſize. Theſe are generally bought by contractors for the navy. But if no ſpeedy and effectual means are taken for the better preſervation and management of the foreſts, in order to procure a regular ſucceſſion of Oak timber, the navy will, in a ſhort time, be deprived of this valuable reſource.

Purlieu Woods are ſuch as are ſituated in the vicinity of the foreſt, and once formed a part of it; they have been diſforeſted by grants from the crown, and are now private property, not ſubject to the laws and regulations of the foreſt.

The average price of the underwood, from eleven to fourteen years growth, is about 6l. the ſtatute acre, but it is ſometimes ſold ſo high as 8l.

The Oak timber in theſe and in private Woods ſeldom attains to ſo large a growth as in the foreſts and chaſes, it is therefore principally bought by carpenters, wheelwrights, &c. for country uſes.

Geddington chaſe is ſuppoſed to contain about 1,400 acres, of which perhaps 1,200 are woodland, the remainder conſiſts of lawns, ridings and viſtas. The whole is the joint property of the duke of Buccleugh and earl Beaulieu, ſubject to a commonage of the adjoining townſhips from may-day to martinmas. It is divided into eighteen parts, in one of which the underwood and timber are cut every year. Theſe parts are fenced as in the foreſt. Although there is ſtill a valuable ſtock of Oak timber in this chaſe, principally of a large ſize; yet the ravages committed by deer and cattle prevent the ſmalleſt poſſibility of obtaining a regular ſucceſſion of Oak timber, and even cauſe a daily diminution in the growth of underwood. If the ſyſtem now practiſed of cutting down all ſuch timber trees as appear mature and in an unthriving ſtate be long purſued, in a few years there will not be a ſingle Oak tree left large enough for the uſe of the navy [e].

The quantity of Oak timber cut down within the laſt thirty years has been very conſiderable, and ſuch a proportion as the woodlands will not be able permanently to ſupply [f].

Northumberland.

Woods in this county are found moſtly on the banks of rivers. Of old Oak timber from 80 to 140 years growth, the probable value may be about 60,000l. of which two-thirds only are proper for building ſhips of great burden.

The demand by the collieries and lead mines for ſmall wood, has induced the proprietors on the Derwent, Tyne, &c. to cut the Oak, Aſh and Elm at twenty-five or thirty years growth; Birch, Willow and Aller (Alder) ſooner.

Plantations on an extenſive ſcale are riſing in every part of the county, and are almoſt in every inſtance doing well. The Larch riſes pre-eminent above the reſt [g]. A fourth or fifth part of the trees planted is Oak; the reſt are Scotch Firs, Larches and Aſh.

The woodlands in the N. and W. parts were ordered to be burnt in the time of queen Elizabeth, becauſe the Moſs-troopers and other banditti ſecreted themſelves in theſe Woods, and iſſuing from them committed great depredations on the neighbourhood [h].

WOO

NOTTINGHAMSHIRE.

The foreſt of Sherwood, is from Nottingham to near Workſop about twenty-five miles in length, and from ſeven to nine miles in breadth. The principal remains of the ancient foreſt Woods are the Hays of Birkland and Bilhagh, being an open Wood of large old Oaks, moſt of them decaying or ſtag-headed, and without underwood, except ſome Birch in one part; it extends about three miles in length, and one mile and a half in breadth. By a ſurvey taken in 1790, there were found 10,117 trees, valued at 17,147l. The land on which they grow is 1,487 acres, 2 roods, 37 perches. A part of this Wood has been taken by grant into Thoreſby park.

Harlow Wood, Thieves Wood, and the ſcattered remains of Mansfield Woods are of ſmall extent, and the timber is of inferior ſize.

In Clumber park are remains of two Woods of venerable Oaks. Since theſe have been incloſed the young trees are ſpringing ſurpriſingly from the acorns.

The ſpirit of planting has prevailed much in this county within forty years. The firſt plantations were chiefly of Firs; but it has been ſince found, that trees of all kinds, well planted and properly ſheltered, ſucceed very well.

The duke of Newcaſtle's plantations within Clumber park amount to 1,848 acres: beſides 190 acres in Martin Wood, 180 acres of Aſh and 410 of Oak, &c. The duke of Portland's in Welbeck park, Carberton, &c. about 1000 acres. The Hon. R. Lumley Savile's 1,680 acres in Morton Grange and Little Morton, part Oak Woods, the reſt Oaks, and planted with Aſhes for hop-poles. A conſiderable part of the Oak plantations were planted with Firs and Larches by the late Sir George Savile, when the acorns were ſown, about forty-four years ago. The larches now (1794) meaſure from thirty to fifty feet in length, and from twelve to forty-eight inches in girth. The Scotch Firs are from twenty to thirty feet long, and from twelve to thirty-two inches in girth.

Charles Pierrepont, Eſq. now lord viſcount Newark, has 981 acres in and about Thoreſby park, the chief part planted with Oak, Aſh, Beech, Spaniſh Cheſtnut, and Elm: 306 acres now (1794) in preparation for planting; and 381 acres, moſtly coppice or ſpring Woods, cut every fifteen years, for hop-poles, hedgewood, &c.

F. F. Foljambe, Eſq. has 600 acres at Oſberton. In Carlton, Charles Melliſh, Eſq. has 154 acres. Taylor White, and Woolaſton White, Eſqrs. have 107 acres 3 roods, and Mr. Joſeph Cowliſhaw 15 acres one rood; Taylor White, Eſq. has alſo 28 acres 2 roods in Wallingwells.

The Duke of Norfolk, at and near Workſop Manor, has 781 acres of Woods and plantations. Jonathan Acklem, Eſq. and others, have fifty acres in Matterſey Woods, in Wiſerton twenty-five acres. Charles Melliſh, Eſq. has 1000 acres in Blyth, &c. chiefly Fir. Lord viſcount Galway has 126 acres in Serlby and Farworth. Robert Sutton, Eſq. has about 750 acres, about ſixty of Fir, the reſt Oak and Beech, in Scoſton. Robert Ramſden, Eſq. at Calton, in Lindrick, 148 acres of Oak, Cheſtnut and Aſh, beſides forty-eight acres of foreſt plantations. Right Hon. Fred. Montagu, thirty-four acres of Oak, Aſh, Elm, &c. in Linby and Papplewick; beſides forty acres in preparation. Sir Richard Sutton, at Farnsfield, has ſeventeen acres. In all about 10,000 acres, chiefly planted ſince the middle of the eighteenth century.

The Woods and plantations in the clay diſtrict north of Trent amount to 3,624 acres. And thoſe in the limeſtone and coal diſtrict, to 916 acres[i].

Of the immenſe plantations lately made, Fir, Birch, Poplar, Aſh, and Elm are the principal trees, though the quantity of Oak is not inconſiderable, but bearing no proportion to the others. Theſe plantations being yet young, a long time muſt elapſe before they will be fit for public uſe[k].

Lord viſcount Newark continues his plantations at Thoreſby, and in the winter of 1801, ſowed twenty acres with acorns; his plants average 60,000 to the acre. The marquis of Tichfield alſo ſowed fifty acres with acorns in 1798 and 1799.

[i] County Report, qu. 1794. [k] Eleventh Report, app. n. 11.

OXFORDSHIRE.

The Beech Woods are confined to the Chiltern country, and conſiſt of trees growing on their own ſtems, producing by the falling of the maſt; very little being permitted to grow on the old ſtools, which are generally grubbed, and ſeedling trees planted in the looſe earth. Theſe Woods are drawn occaſionally, and never felled at once, except for the purpoſe of converting land into tillage, which has been much in practice of late years. The Beech Wood is ſold for poles or billet. It requires ſome judgment to thin theſe Woods ſo that the ſtock may not overhang the ſeedlings. The ſucceſſion of young trees is much injured by admitting cattle or even ſheep. There are ſome Oak and Aſh trees diſperſed among the beech; they ſeldom grow to any great bulk, and are not very numerous. In the vicinity of Staunton St. John are Woods of timber trees with underwood. The ſoil is a ſtrong clay, well adapted to the growth of Oak. Many ſpots of Woodland of this deſcription are diſperſed about the country. Coppices do not abound; indeed there are few of any extent, except in the foreſt of Whichwood, and theſe have trees in them[l].

The Eleventh Report to the Commiſſioners of Land Revenue ſtates, that many Woods have been grubbed and converted into tillage, but not a ſingle plantation of Oak in the county, except where gentlemen have planted for ornament, trees of quick growth having been generally preferred: and that this county does not produce more timber than is ſufficient for its own conſumption.

RUTLANDSHIRE.

Oak timber not much raiſed, and little fit for the navy. The beſt is uſed for building, canals and navigations: the coarſer for fences, gates, hurdles, &c. ſold at Spalding and Peterborough fairs, and carried into the fen country.

Underwood is cut from twelve to ſixteen years growth[m].

No plantations of Oak or other trees of any conſequence have been made[n].

SHROPSHIRE.

Navy timber greatly diminiſhed, perhaps not one-fourth remaining of what there was thirty years paſt. Great quantities of timber have been taken down in conſequence of farms having been enlarged. The joining of fields has prevailed much: and the occupiers of land frequently abuſe hedge-row trees.

Coppices are generally fallen from twenty-one to twenty-five years in growth, and all the poles are barked. Kind-growing ſaplings are generally left, and if promiſing, at a ſecond fall they are ſometimes permitted to ſtand for timber. Coppices fallen at eighteen years growth are converted into cordwood for the forges and not barked. The conſumption of underwood in forges and collieries is very conſiderable; and the price of land is too high for planting. The underwoods however are ſtill of conſiderable extent, and if the young Oak plants were carefully preſerved, future groves of Oak might ſtill be raiſed. There are perhaps few counties of equal extent that have more abounded with fine Oak timber than this. Within about thirty years the ſupply for the navy and other uſes has been very great, perhaps to the amount of 200,000l. But at preſent there are very few eſtates that could furniſh timber for a ſeventy-four gun ſhip[o].

The late Rev. J. R. Lloyd, of Aſton near Oſweſtry, planted 65,440 Oaks; and in 1793 and 1794, 60,020 more. The ſame years he alſo planted 9,300 Scotch Firs.

SOMERSETSHIRE.

This county is partially wooded, and on account of the demand from the collieries, the Wood is very irregularly

[l] County Report, 4to. 1794. [m] County Report, 4to. 1794.
[n] Eleventh Report. [o] Idem.

Digitized by Google

gularly cut. Kingſwood covers about 230 acres; the timber is chiefly Oak, but it does not get to any large ſize. The underwood is cut for wreaths or faggots. The valleys are in general richly laden with Elm, which acquires a good ſize in the hedge rows; but the method of lopping off the ſide branches, to what is here called a beſom head, cannot be too much execrated. On the northern declivity of Mendip hills are ſome good coppice Woods. On the ſouthern declivity are alſo ſome coppice Woods, but being expoſed to the weſtern breezes, theſe are not ſo productive. In the eaſtern part of the county there are ſome large and productive Woods, which being near the coal-works are very valuable. Many beautiful plantations are alſo interſperſed, which are not only an ornament to the reſpective ſeats to which they belong, but are in themſelves a fertile ſource of annual profit.

The ancient foreſt of Selwood, on the verge of which Frome ſtands, appears to have compriſed a woody vale of about 20,000 acres, 18,000 of which are now converted into arable and paſture land; the remainder continues in a ſtate of coppice Wood. The timber is chiefly Oak and Aſh, which though not of large growth, are very good of their kinds, and ſell well in the neighbourhood. The underwood is moſtly Hazel, Aſh, Alder, Withy and Birch; ſome of which ſell as high as 16l. an acre.

This foreſt was diſafforeſted about the ſeventh of Charles I. and divided into three portions, one whereof was allotted to the lords of manors, another to the commoners, and a third to the crown. The latter was ſold to the adjoining landholders. No great quantity of woodland has been grubbed within the laſt forty years; but much new ground has been planted, particularly on the hills belonging to the marquis of Bath, Mr. Beckford, and Sir Richard Hoare.

Theſe woodlands are in general in a ſtate of coppice wood, with timber chiefly Oak; but the ſoil, particularly in the vallies, being of a ſtrong yellow clay, is ſo cold and retentive, that the Oak trees, though ſpringing up ſpontaneouſly in great abundance, get moſſy and dead-topped, and few of them come to a large ſize: yet from the neighbourhood of good inland markets, the profit from woodland is nearly double that of the adjoining land in arable or paſture; and the profit ariſing from the new-planted hills, particularly the ſandy parts, has been, in many inſtances, near ten per cent on the original expenſe of planting and fencing [p].

Staffordshire.

This county ſtill continues well ſtocked with timber, notwithſtanding the immenſe quantity that has been lately cut down. The beſt-timbered eſtate is that of Lord Bagot near Abbot's-Bromley. The Woods extend over many hundred acres, and almoſt wholly conſiſt of Oak, a very large quantity of which is now quite mature, and ſome even decaying. Many carry timber to the length of ſixty or ſeventy feet: and in the park are many hundreds of very extraordinary bulk, containing from 200 to 400 feet of timber each. Several might be picked out worth 60 guineas a piece, and ſome even more. Some of theſe trees are mentioned by Dr. Plott as full-grown timber in 1686. It is ſaid that one hundred thouſand pounds have been offered for theſe Woods. The ſucceſſion Woods and young plantations are very conſiderable and ſtill continuing. Theſe are made ſometimes by ſowing acorns with wheat after ſummer fallow: ſometimes by ſetting out young plants, in which caſe, at the end of one or two years, they are cut off at the ſurface, the ſecond ſhoot thriving much better than the firſt, which was checked by tranſplanting. After a Wood has been cut down, ſometimes it is replanted by ſtriking in with a pick-axe acorns and other ſeeds of foreſt trees or underwood. All theſe methods have been attended with ſucceſs.

The ſecond-timbered eſtate is Chillington, the property of Thomas Giffard, Eſq. Timber to the amount of 30,000l. has been ſold within twenty years, and that remaining is thought to be worth at leaſt an equal ſum. The ſucceſſion Woods and young plantations are very extenſive, and of luxuriant growth. In theſe Oak has been particularly attended to, but there is alſo a variety of other timber trees extremely promiſing in growth.

Upon the pleaſure grounds and eſtates of lord Dudley, at and near Himley, are large quantities of well-grown timber, and very extenſive Woods and coppices of Oak.

The timber and plantations at Teddeſley park, Sir Edward Littleton's, are very conſiderable. Manſley Wood is extenſive: beſide which there are many other coppices, dingles and clumps of full grown Oak, Aſh, and other timber. The ſpring coppices and young plantations, cover at leaſt 100 acres; and in them Oak has been an object of particular attention. Theſe plantations are generally upon poor cold land; a gravelly marl or clay bottom, on which Oak ſucceeds well, and being of no great value for corn or paſture, is very properly applied to the growth of timber and underwood.

Wrotteſley eſtate, the property of Sir John Wrotteſly, Bart. contains ſome conſiderable Woods of well-grown timber: alſo extenſive plantations of more modern growth.

An Enville, lord Stamford's, the Woods and plantations are very extenſive, and well-ſtocked with timber trees and underwood, among which Oak predominates. The Woods of Upper Areley are very large, and well ſtocked with Oak of various ages. Hagley park, cloſe to the borders of this county, contains great quantities of exceeding fine timber, of a firſt rate quality. The pariſh of Harbourne is well wooded. The Biſhop's Woods, near Eccleſhall, are ſaid to contain 1,300 acres: a certain portion of them is cut down every year. Madely Woods, near Newcaſtle, are well ſtocked with Oaks; they were formerly a park.

The plantations at Fiſherwick, lord Donegal's, are of little more than twenty years growth, (in 1796) but very promiſing.

Sandwell park and eſtate, the earl of Dartmouth's, is well ſtocked with all kinds of timber, particularly Oak. The Patteſhall eſtate, Sir Robert Pigot's, ſtill contains large quantities of mature timber, although conſiderable quantities have been cut lately.

Broughton pleaſure-grounds, Sir Thomas Broughton's, abounds with plantations, clumps, and ſhady ſpreading trees, particularly ſycamores. There is a promiſing coppice of Oak on the other ſide of the road.

Hilton park, belonging to Mr. Vernon, contains plenty of flouriſhing Oaks. In the pleaſure grounds are ſome very fine well-grown Oaks and a great variety of other timber trees. The rides and plantations are very extenſive, and bear evidence of the planter's vigilant attention. Many Larches and Firs of his own planting contain twenty feet or more of timber.

Burntwood, near Aſhley common, belonging to Mr. Meynell, is very extenſive, and well ſtocked with young Oak.

The eſtates of Mr. Gough, at Perry Bar, Oldfallings, near Buſhbury, and Walton Grange, near Gnoſhall are all well timbered. Perry park and neighbourhood has much ripe timber, and conſiderable young plantations of every ſtage of growth. Oldfallings eſtate and neighbourhood is plentifully ſtocked with well-grown Oak and other timber, and Walton Grange has an excellent Oak coppice, of conſiderable extent. Bentley eſtate, Mr. Anſon's, near Walſall, is extremely full of Oak, both in coppices and hedge-rows. At Great Sugnall, near Stafford, Mr. Turton's, are ſome ſmall neat plantations, among which Oak has not been forgotten. Conſiderable Woods and plantations grow on the Shutborough eſtate, Mr. Anſon's, as well as on that of Sir William Wolſeley; and alſo upon Mr. Curzon's, near Rudgeley. The eſtate of Mr. Fowler, at Pendeford, is well wooded, in hedge-rows, young plantations, ſingle trees, and clumps of very fine well-grown Oak; it has alſo a very promiſing coppice of Oak. Other ſmaller eſtates are well ſtocked with timber, particularly that of Mr. Fleeming, at the Wergs, near Tettenhall, where are ſome Oaks worth thirty guineas each. Upon the whole, the county is well timbered, and has now in it ſucceſſion growths ſufficient for the ſupply of a great length of time.

[p] County Report, 8vo. 1798.

Digitized by Google

Plantations have been made to a great extent, and with uncommon ſucceſs, on the ſteep moorland hills, particularly thoſe of Dillorn, Kingſley, and Oakamoor; the Dillorn Woods alone form a chain of three or four miles in length, and conſiſt of tall ſtraight Oaks and Aſhes, in general ſo well filled up with underwood, as to be cut in falls at ſeven years growth, for rods and ſtaves uſed for crates in the pottery. John Holliday, Eſq. has proved experimentally the great advantage of planting barren impracticable precipices, large tracts of which ſtill remain in the north of Staffordſhire, not worth 1s. an acre.

This gentleman, in 1789, planted 10,000 Oaks on twenty-nine acres nearly; 94,000 Beech; a few Cypreſſes, white and hemlock Spruce Firs and Ilexes; 7,900 Larches; ſome Lombardy and black Italian Poplars, and weeping Willows.

John Sneyde, Eſq. of Belmont, planted 30,000 Oaks between 1784 and 1786; and 27 acres, 2 roods, 18 perches with mixed trees: 6000 Aſhes, 14,300 Beeches, 8000 Cheſtnuts, 4,262 Elms, 44,100 Scotch Firs, 5,500 Spruce Firs; 700 Ilexes; 13,000 Larches; 5,500 Sycamores; beſides Crætægus Aria, Horſe Cheſtnut, Lime, Plane both oriental and occidental; Lombardy Poplar and Mountain Aſh, in ſmall quantities. Alſo 11,000 Larches in 1794 and 1795.

James Beech, Eſq. of Shaw, near Cheadle, in 1798 and 1799, planted 11,000 Oaks, 9000 Aſhes, 18,000 Beeches, 1,800 Elms, 3000 Larches, 17,000 Mountain Aſhes, and 9000 Sycamores.

Henry Vernon, Eſq. of Hilton park, near Wolverhampton beforementioned, planted 11,600 Oaks in 1798 and 1799, and thirty acres with other trees; in 1797 and 1798, 6240 Silver Firs[q].

Yet notwithſtanding the above account of conſiderable old Woods and new plantations, it is ſtated in the Eleventh Report of the Commiſſioners of Land Revenue, that more Wood has been cleared than planted, that the plantations which have been made are of trees not fit for the navy, and that there is but little commonable Wood except in the foreſt of Needwood, and great part of that has been cut down lately.

Suffolk.

The ſtrong loams of this county formerly contained conſiderable quantities of large Oak; theſe, as in every other part of the kingdom, have been much leſſened, and the ſucceſſion bears no proportion to the growth that preceded it. Improved cultivation is the cauſe: rough paſtures, overrun with thorns and briars, and broad hedge-rows, were nurſeries of timber; as land became valuable, theſe have been cleared: with this obvious improvement, timber has of courſe declined; a circumſtance not to be regretted, ſince corn and graſs are products much more valuable.

Underwoods are not generally productive in this county. The profit of them is leſs than that of adjoining lands under other products.

In moſt inſtances, planting has been performed more with a view to ornament than profit: how far they may be made to unite, is a ſubject worthy of attention[r].

In one of the returns to the Commiſſioners of the Land Revenue, it is ſaid that timber is decreaſed in Woods and hedge-rows, *as it ought to be;* that much timber, and the improvement of arable land, are incompatible; and that Suffolk, being a highly improved county, timber has moſt profitably decreaſed, the improvements being ten times the value of the timber. The chairman of the quarter ſeſſions at Bury returns, that the ſcarcity of timber ought never to be regretted, for it is a certain proof of national improvement, and for royal navies, countries yet barbarous are the only proper nurſeries. All this is true to a certain degree. Land that can be uſed profitably for corn or graſs ought not in general to be planted; and hedge-rows ſhould not be encumbered with trees; but yet there are in all counties ſpots better applied to this purpoſe than any other; odd corners at leaſt, and belts for ſhelter, may be introduced almoſt every where, even in the beſt cultivated counties. Every county ought to furniſh its own coppice Wood, and timber for all rural purpoſes. Naval timber ſhould be the object of the royal foreſts. I cannot think it expedient to depend wholly upon importation for this neceſſary article.

The chairman at the quarter ſeſſions at Beccles returns, that the weſtern ſide of that diviſion has had much timber on it, but that at preſent it is in a very decreaſing ſtate; that ſome large plantations have been made, in ſome of which much young Oak is growing; but that the planting bears no proportion to the decreaſe.

Samuel Kilderbee, Eſq. planted ten acres with Oak in 1793; and ſeventeen acres and a half at Badingham and Glemham in 1795 and 1796.

Job Hanmer, Eſq. planted 8,100 Oaks at Holbrook-hall near Sudbury, in 1792 and 1793.

William Wollaſton, Eſq. of Great Finborough, planted twenty acres with Aſh[s].

Surrey.

This county abounds in waſtes and commons, to the amount, as is ſaid, of 96,000 acres, all of which, that are not fit for agricultural purpoſes, might be planted for coppice Wood and timber. Norwood, near London, contains about 600 acres, 250 acres of which is an incloſed coppice Wood, full of Oak; but the trees are not ſuffered to grow up to any ſize. The remainder of Norwood is foreſt, conſiſting of ſtraggling Oak pollards. Dulwich college has the property of moſt of the incloſed Woods.

Farnham and Crookſbury heaths contain 3,700 acres of deep ſandy ſoil. The valuable plantations of Firs on theſe heaths prove to what a profitable purpoſe they may be applied. Twelve acres were planted 1776 with Scotch Firs four years old. In 1788 they were thinned out. The number at preſent (1794) ſtanding, are 18,531, valued at 573l.

Between Godſtone and Weſterham is Stafford Wood, 150 acres, part of which conſiſts of Oak, Beech, and Birch underwood, with ſome timber of a large ſize: ſeveral Oaks were cut down a few years ago containing two loads of timber in each tree. Mr. Eden, the late lord of the manor, planted a great number of trees, which have been deſtroyed for want of being protected from cattle[t].

Sussex.

This county has always been celebrated for the growth of its timber, principally Oak. It overſpreads the Weald in every direction. Large quantities of Beech are raiſed upon the chalk hills. The great demand for bark, has occaſioned large falls of Oak; and the more eaſy communication with the ſea-ports has occaſioned greater ſupplies to be ſent to the dock-yards than the country will be able to ſupply in future. The quantity now ſtanding, of a ſize fit for the royal navy, compared to what it has been within half a century, is inconſiderable; and as there is no regular ſucceſſion in reſerve, the ſupply muſt annually grow leſs.

The export coaſt-wiſe from one port in this county, from 1763 to 1767, was only 4,769 loads of timber, and 454 tons of bark; from 1788 to 1792, 19,884 loads of timber, and 2,646 tons of bark. A load of timber is fifty cubical feet.

So early as the reign of Edward VI. thirty-ſeven hoys, laden with timber, went out of Rye harbour in one tide, and not one engliſh mariner among them. The whole country round was a foreſt; inſomuch that in 1591 a man was ordered to depart the town of Rye, he being a huſbandman, and the place not fit for one of his profeſſion. Even now, in ſome parts of the county, the incloſures are very ſmall for the benefit of the timber, and round each is a thick Wood ſeveral rods wide.

The underwood is uſually cut from thirteen to ſeventeen years growth, for hop-poles, faggots, and cord-wood for charcoal. Young Oaks that grow ſcrubby are felled at thirty or thirty-five years, for poſts, rails and repairs.

In a Wood well planted with timber, underwood never comes to any ſize; and more loſs is ſuſtained by

this, than gain is made by the growing timber. There are ſeldom any *tellows* or ſaplings remaining; a good ſucceſſion therefore of young Oak ſeldom follows a fall of old timber. Some prefer timber from ſtubs to the growth from ſeed; the ſucceeding ſhoot ſpringing up three feet the firſt year, and very fine timber, of two loads to a tree, having been cut from ſtubs [a].

Earl Winterton planted in Shillinglee park 14,269 Oaks, and 2,613 Lombardy Poplars.

Warwickshire.

There are large Woods and much timber in this county, particularly in what was formerly the foreſt of Arden. The underwood is cut down every ten or twelve years, and converted into ſtails, faggots, brooms, hoops, &c. and wattled hurdles. The white poles, which are twenty-four years growth, are converted into rails, ladders, hoops, and various other articles by cloggers, bruſh-makers, turners, &c. The price of theſe Woods is from 3l. to 8l. an acre, according to the quantity of white poles and Oak timber. Thoſe Woods which grow Oak well, anſwer beſt by being gradually converted into groves, by ſetting up Oaks either from maiden plants or ſtubs, and by previouſly dibbling in acorns where wanted [x].

Westmoreland.

At Whinfield Foreſt, and at Lowther-hall, the ſeat of the Earl of Lonſdale, are very extenſive plantations, where many of the trees have grown to an uncommon ſize. Several of the Oaks at Lowther-hall have been valued at 60l. a piece. There are many ſmaller plantations through the county, where the Wood ſprings with a degree of vigour hardly to be expected in ſuch bleak and expoſed ſituations.

On the diviſion of Kendal common, part of a very high and rocky hill not capable of any other improvement, Scotch Fir, Larch, Oak, Aſh, and other trees were planted, and they are all very thriving. The banks of the lakes are adorned with very beautiful coppices.

The biſhop of Landaff has planted, on ſome high ground near Ambleſide, above 100 acres with Oak, Elm, Aſh, Beech, Sycamore, Scotch Fir and Larch. He is doubtful whether the climate be not too cold for any of them except the two laſt [y].

In 1788 he planted 3,200 Oaks; 20,000 Aſhes on eleven acres, 2,000 Beeches, 2,000 Elms, 48,500 Larches, 650 Carolina Poplars, and 2000 Sycamores.

I. C. Curwen, Eſq. ſet 500 buſhels of acorns, and planted above 50,000 Oaks on 200 acres bordering on Winander Mere, in 1795 and 1800. In october 1800 and april 1801 he alſo planted 271,420 Oaks, 229,476 Larches, 240,800 Aſhes, 23,600 Scotch Firs, 8,120 Beeches, 21,540 Birches, 10,000 Alders, and 10,000 Elms, in all 814,956.

Dr. H. Ainſlie of Dover-ſtreet, London, planted on high ground between the lakes of Winander Mere and Coniſton, from 1789 to 1802, 91,800 Larches, 33,650 Scotch Firs, 11,200 Oaks, 3000 Aſhes, 1400 Elms, 700 Beeches, 100 Spruce Firs, and 100 Silver Firs [z].

Wiltshire.

This county was once well wooded. The introduction of pit-coal has very much leſſened the conſumption of Wood for fuel, and this ſlackened the attention to the preſervation of Wood. In many parts of the outſkirts there are large and valuable Woods, but in frequent inſtances much injured by being ſubject to common rights. The uſes of underwood being many, as for hurdles and hedging, ſpars for thatching, wheelrights and carpenters work, ſheep-cribs and implements in huſbandry, &c. the preſervation of it is become an object of conſequence, eſpecially ſince the late great advance in the price of coals.

Oak, Aſh, and Elm are natural to the county. The cold ſoils on the weſt ſide are favourable to Oak; the ſands of the ſouth part to Aſh, and the gravelly vallies and deep loams of various parts, to Elm; and although many parts appear to be bare of timber, yet there are ſo many others where the ſoil is peculiarly adapted to its growth, that the produce of the county is fully equal to its conſumption.

A great ſpirit of planting has for ſome years paſt been diffuſed through every part of the county. There are few parts of the kingdom where timber trees, particularly Elms in hedge-rows are better preſerved, or leſs damage done by trimming up the ſide branches, than in the county of Wilts [a].

The marquis of Bath at Longleat has planted from 50,000 to 100,000 trees yearly for twenty years: chiefly heath land at the foot of the Wiltſhire downs near Warminſter.

Worcestershire.

The extenſive Woods and Foreſts of this county, ſo very conſiderable in early times, have almoſt diſappeared. Feckenham foreſt has ſunk entirely under the continued demands of the ſalt-works at Droitwich. The Woods of Hagley and Uffmore are ſtill of conſiderable extent, and ſome idea of the former abundance may be formed ſtill, on thoſe parts which border on Herefordſhire. Through a conſiderable part ſmall tracts of woodlands are frequent, and they furniſh timber, chiefly Oak and Aſh, with ſome Beech, of excellent quality. The hedge-rows are every where crowded with Elm, and though the preſent cuſtom of lopping and pollarding muſt certainly injure their growth, they often produce timber of conſiderable dimenſions. Elm is conſidered as the principal growth, there is however in many parts as fine Oak and Aſh as the kingdom produces. The principal uſes to which underwood is applied are hop-poles and the making of charcoal for the iron-works [b].

Yorkshire.

Eaſt Riding.

There are few ſpring Woods in this riding. Timber trees, except thoſe which are within view of a houſe, or for ornament, are cut as beſt ſuits the fancy of the owner. Many new plantations, as well as thoſe of longer ſtanding, are exceedingly injured for want of draining [c].

There is very little Oak timber fit for the navy; a ſmall quantity in North Holderneſs, and ſome good in Ouſe and Derwent Wapentake.

Many new incloſures have been made in the laſt thirty years, but Aſh has been more commonly planted than Oak in the hedge-rows.

In Ouſe, on Derwent Wapentake, many Oak hedge-rows have been grubbed up, and but few planted, many however ſtill remain. In the reſt of the Riding there are ſcarcely any.

Very extenſive plantations are yearly making, but they are chiefly of Larch, Aſh, Beech and Fir; ſome Oak, but generally upon ſoils too thin for the growth of large Oak timber [d].

North Riding.

Woods comparatively ſmall, when the extent of this Riding is conſidered.

	Acres.
The coaſt	3,000
Cleveland	1,500
Vale of York, with the Howardian hills	11,000
Ryedale, with the eaſt and weſt Marſhes	6,000
Eaſtern Moorlands	3,000
Weſtern Moorlands	1,000
	25,500

There is beſides a conſiderable quantity of timber in the hedge-rows, particularly in the vale of York, the Howardian hills, and Ryedale; though far leſs than heretofore. The ſpontaneous produce of the woodlands is principally Oak, Aſh, and Broad-leaved or Witch Elm: the produce of the mountains much

Birch and Alder. Few large timber trees are now to be found, except on the eſtates of C. S. Duncombe, Eſq. and lord Carliſle.

Planting has been little attended to. The late Sir Charles Turner made ſome extenſive plantations on the Eaſtern Moorlands, near Kildale; but as he died ſoon after, they were not properly attended to. One very large tract is entirely deſtroyed; of what is left however there is enough to ſhow that trees will thrive upon the higheſt, moſt expoſed and barren of the moors: the kinds chiefly planted are Scotch Fir, Spruce and Larch, with ſome Oaks and a few Beech.

The late Francis Cholmeley, Eſq. and his ſon Francis Cholmeley, Eſq. of Branſby, have made ſome conſiderable plantations, chiefly of Larches and Firs, upon the ſides of the hills, and other barren parts of their eſtates. They were begun about thirty-eight years ſince, and have been annually encreaſed from that time: ſome of the firſt-planted Larches have been cut down and meaſure from forty to fifty-five feet in length, and from three to four feet four inches in girth. Larch being ſo valuable, thriving ſo well, and being of ſuch quick growth, that is intended chiefly to be planted in future [e].

Thomas Richardſon of Handale Abbey, Eſq. planted between october 1789 and april 1791, forty acres with mixed timber trees, Oak, Aſh, Elm, Beech, Sycamore, Alder, Larch, Spruce and Scotch Fir, White Dutch and Black Carolina Poplar; in number 121,413.

The Rev. William Smith planted at Flaxton, in 1796 and 1797, 1615 Oaks, 200 Aſhes, 300 Beeches, 1200 Birches, 50 Cheſtnuts, 100 Horſe Cheſtnuts, 200 Wych Elms, 1200 Scotch Firs, 200 Spruce Firs, 3,800 Larches on eleven acres, 100 Alders, 200 Poplars, and 200 Sycamores.

John Hutton, Eſq. of Marſke near Richmond, between the firſt of october 1799, and the firſt of april 1801, planted five acres, with 4,236 Oaks, 3,059 Larches, 2,607 Spruce Firs, 3,341 Aſhes, 575 Beeches, and 424 Poplars and Birches. Alſo fourteen acres, with 5,400 Oaks, 7,300 Larches, 5,700 Scotch Firs, 4,500 Spruce Firs, 5,200 Beeches, 3,500 Sycamores, 4,500 Elms, 5,300 Aſhes, 1,600 Birches, 2000 Alders, 2000 Mountain Aſhes, and 800 Silver Firs [f].

Weſt Riding.

Much Oak and Aſh Wood are grown in this riding, and it meets with a ready market at the ſhipping and manufacturing towns: much is alſo uſed at the mines and collieries. The Duke of Norfolk has above 1,500 acres of woodland in the pariſh of Sheffield. Mr. Beaumont of Bretton-hall poſſeſſes a great deal of valuable timber. At Kirkſtall Abbey, about three miles from Leeds, is much Oak Wood [g].

John Scolefield Firth, Eſq. at Kipping near Bradford, on eight acres two roods, planted 1900 Cheſtnuts, beſides ſetting 1400 Nuts.

Richard Slater Milnes, Eſq. of Foyſton near Ferrybridge, planted in 1788 and 1789, 225 acres, with 20,000 Engliſh Elms and other trees, among which were 200,000 Larches, from two to four years old, 2000 on an acre.

The Rev. Charles Hope of Derby, planted in the chapelry of Bradfield, between 1785 and 1792 on ten acres 41,000 and on thirty-two acres about 168,000 mixed trees, Oak, Beech, Cheſtnut, Sycamore, Broad-leaved Elm, Larch, Scotch Fir, and Aſh [h].

WALES.

North Wales.

Angleſea.

Although this iſland was famous for its Woods, it is now a received opinion that trees will not grow upon it, except on the banks of the Menai, where there are fine plantations. There are however many ſmall ſpots in the neighbourhood of gentlemens' ſeats, which by being planted thick and properly protected are in a very promiſing condition.

[e] County Report, 8vo. 1800. [f] Tranſ. arts.
[g] County Report, 8vo. 1799. [h] Tranſ. arts.

Caernarvonſhire.

This county, once incumbered with Woods, is now left naked and bare; except around gentlemens' ſeats ſcarcely a tree is to be ſeen, and thoſe are not very numerous. They are all ſituated near the coaſt, and yet plantations thrive very well. There is no county in North Wales ſo deficient in Woods as this and Angleſey. The old foreſts have been cut down, and their places have not been ſupplied with new plantations.

Denbighſhire.

This county is pretty well wooded with old plantations. Mr. Middleton of Chirk-Caſtle has planted more trees than any gentleman in the county. The number of acres is about 700, beſides old Woods.

Flintſhire.

This county is finely interſperſed with Woods, and every gentleman's ſeat is ſurrounded with plantations. The Woods are in general old, and very few young plantations are to be ſeen.

Merionethſhire.

This county, although better wooded than Caernarvonſhire, is yet in many places very bare of trees. Oak is the principal timber raiſed, and the woodlands are frequently very little attended to.

Montgomeryſhire.

In the numerous and extenſive rich vales with which this county abounds, there are many old plantations of Oak, which ſome of the proprietors are cutting down, without ſupplying their places. Others have not altogether overlooked the rearing of young plantations. Theſe grow very well, conſiſt of different kinds of trees, and are in general better protected from the depredations of cattle than in many of the Welſh counties [i].

On account of the improvement of roads, much more timber has been felled in this and the other counties of North Wales, than they can permanently ſupply [k].

SOUTH WALES.

Brecknockſhire.

Woodlands of all other things do the moſt diſcredit to the diſtrict of the hundred of Falgarth and the vale of Uſk; being kept under no ſyſtem, nor having the ſmalleſt attention paid to their preſervation. Nothing more would be requiſite to encourage the growth of young timber, than to incloſe any ſpot of land, and the Oak and Aſh will riſe of their own accord. The former of theſe is preferable to the Engliſh.

The hundred of Builth is tolerably well wooded, notwithſtanding the great quantity that has lately been felled. In defiance of all difficulties, ſome young plants eſcape the general deſtruction made by the brouſing of cattle; and every ſpot into which the plough, the cattle or the water has not found admiſſion, is covered with ſome kind of Wood, except the high hills [l].

In this county are coppices of Oak of conſiderable extent, which if ſtrictly preſerved (according to the letter of the acts of 35 Hen. 8. c. 7. and 13 Eliz. c. 25.) would furniſh more than ſufficient Oak timber for domeſtic uſes, and ſome to ſpare for the uſe of the navy, for which there is very little at preſent [m].

Cardiganſhire.

The county has little Wood, and that little is yearly leſſening, and what is left is much neglected.

Thomas Johnes, Eſq. has made very conſiderable plantations about his beautiful ſeat at Hafod. In 1797 and 1798 he planted 10,000 Oaks; in 1798 and 1799, 165,000 Oaks, beſides ſetting acorns; 25,000 Aſhes; 880,000 larches; 50,000 Alders, with Elm, Beech, Birch, Aſh, and Mountain Aſh, in all 250,000.—The total amount of trees planted between 1795 and 1801,

2,065,000

Digitized by Google

2,065,000, of which 1,200,000 are Larches; beſides fifty-five acres ſown or planted with Oaks*.

Caermarthenſhire.

The prodigious havock that has been made of late years among the Woods is truly alarming. From being a well-wooded county, it is now become the reverſe. The vaſt quantities of timber which every part produced till lately, ſeems to have begot in the proprietors an indifference as to the protection of their Woods.

Foreſt trees of all ſorts thrive well, particularly on the ſlopes of hills ſheltered from the S. W. wind, and in the vales; of which the extenſive and valuable Woods about the ſeats of Lord Dynevor, Mr. Vaughan, of Golden Grove, &c. afford undeniable proof.

Glamorganſhire.

The plantations in this county are numerous, and managed in a way that does credit to the reſpective proprietors. John Morris, Eſq. of Claſemont, is one of the firſt improvers. He has been a planter above twenty-five years, in which period he has planted above 500,000 trees, principally Beech, Oak and Aſh; many Sycamores, Firs, Larches and Birches, beſides Spaniſh Cheſtnuts, Plane, Elm, and Lombardy Poplars. He has raiſed nearly all his trees from ſeed; when they are about three feet high, he plants them out at a yard diſtance; and when they nearly touch each other, they are taken out to make other plantations: ſo that every young Wood is a nurſery. The trees are examined annually, and ſuch as are not thriving are hoed round like turneps. When the ſoil is very adheſive a crop of potatoes is introduced. All ſtagnated water is carefully drained off. Open to the ſea breezes, he finds Sycamore and Elm particularly proper. This gentleman's regular courſe of planting is about 10,000 trees annually.

Pembrokeſhire.

Woods are rather ſcarce, particularly towards the weſtern coaſt. The interior part is better wooded; the growth is for the moſt part ſlow, but the Oak is remarkably full of heart. The moſt conſiderable wooded eſtate is Slibec', lying on the eaſtern branch of Milford Haven.

Lord Milford and Mr. Barlow have a conſiderable quantity of timber trees yet remaining upon their eſtates, which, with a few ſurviving groves about Slibech, form the bulk of the preſent ſtock of timber below the mountains. Some groves in Dyffryn-Gwein, belonging to Mr. Langhorn of Orlandon and others; Penkelly Woods, belonging to Mr. Lloyd of Bronwidd, and Pfynonne Woods belonging to colonel Colby, are the moſt extenſive on the mountains. There is hardly any eſtate in the interior and eaſtern parts without ſome plantations. The ſtock however upon the whole is ſo reduced, that there is much reaſon to apprehend a few years more will bring the farmer to the neceſſity of importing Wood for the ordinary purpoſes of huſbandry.

The Eleventh Report of the Commiſſioners of the Land Revenue ſets forth, that every body cuts down, and no one plants, or encourages the growth of Oak timber in any ſhape in this county. That there have been no commons divided, except Narberth mountain, which was formerly a foreſt of Oak, but not within memory. It is now all encloſed and not one Oak planted.

Radnorſhire.

The ſoil of this county is remarkably well adapted to the growth of Oak: even in the upper diſtrict, there are ſome remarkable inſtances of its partiality to the ſoil. Some hundred acres of common hills are at preſent covered with timber, without any incloſures: they are moſtly on the ſide of hills, ſteep banks, or rocks, where the trees were in ſome meaſure protected from the brouſing of cattle, during their tender age.

Not the ſmalleſt care is taken of the woodlands by the land-owners in general, but they are abandoned to

* Tranſ. Arts.

the mercileſs axe of the tenants and cottagers. The whole county was probably one immenſe foreſt; and were it left to itſelf one century, would all be covered with timber again, chiefly Oak and Aſh. The Larch and the different ſpecies of Fir and Pine thrive uncommonly well here*.

SCOTLAND.

Aberdeenſhire, Banffſhire, and Moray.

The earl of Fife planted about 7000 acres of bleak and inhoſpitable moors, with riſing and flouriſhing trees, between 1757 and 1787.

He began firſt with incloſing his park at Duff Houſe, in the county of Banff; this park is about fourteen miles round, and had not a tree, nor was it believed that any Wood could thrive ſo near the coaſt. Now however there is every kind of foreſt tree in a moſt thriving ſtate.

His great plantations from 1769 to 1787, were near Innes Houſe in the county of Moray. Between february 1784 and march 31ſt, 1787, 549 acres and a half were planted with 676,566 foreſt trees of all ſorts, of which 266,600 were common Firs, 65,160 Oaks, 64,306 Beeches, 50,000 Larches, 100,000 Birches, 29,500 Mountain Aſhes, and 22,000 Cheſtnuts. Beſides theſe incloſures there are 4746 ells of hedge and belt: and about 60,000 Firs, and 100,000 Oaks, Birch, Aſh, Larch, &c. planted ſince 1784, in Aberdeen and Banff.

Between 1769 and 1774, 604 acres and a half about Innes, &c. were planted with 1,836,500 foreſt trees, of which 1,660,000 were common Firs: beſides 23,750 ells of dyke.

Between 1775 and 1778, ſeventy-eight acres about Innes were planted with 335,500 foreſt trees, of which 295,000 were common Firs.

Between 1779 and 1783, 1781 acres and a half about Innes were planted with 2,216,385 foreſt trees, of which 1,476,820 were common Firs, 98,313 Larches, and the ſame number of Oaks, Birches, Mountain Aſhes and Beeches.

The whole number of trees planted in theſe eighteen years 4,323,386, of which 3,758,420 were common or Scotch Firs, and 296,973 Oaks.

In 1795 and 1796 a large plantation was made at Rothemay in Banffſhire. Total 47,376, of all ſorts of foreſts trees; beſides flowering ſhrubs and tranſplanted trees, of which a vaſt number about the houſe, waterſide, and through all the old Woods.

In his lordſhip's Fir Woods in the foreſt of Marr, Aberdeenſhire, which are all natural, there are trees that meaſure eighteen feet.

Between 1797 and 1801, were planted in Duff-Houſe Park, and in incloſures and clumps on the ſides of the turnpike road, amounting to ſixty acres, beſides the belts on the ſides of the new road, 18,800 Larches, 3000 Aſhes, 4900 Oaks, 4900 Alders, 4000 Beeches, 4900 Birches, 2200 Poplars, and 5000 Elms.

The belts on the ſides of the new road, with different clumps amounting to forty acres, were planted, the greater part of them in 1802, and were to be finiſhed in 1803. There had been planted 20,000 Larches, 5000 Firs, 3000 Aſhes, 2000 Elms, 20 Horſe Cheſtnuts, 300 Sycamores, 5000 Oaks, 200 Birches, 200 Alders; in all, 85,500 trees, on 100 acres.

Planted at Delgaty Caſtle ſince 1799, 114 acres with 172,400 trees, of which 62,600 are Larches, 45,400 are Firs, 13,100 are Oaks, and 38,000 Birches.

On the eſtates in the pariſhes of Rothemay, Keith and Grange, ſince the year 1797, have been planted 347,800 Larches, 72,100 Oaks, 70,400 Elms, 73,490 Beeches, 205,600 Firs, 90,000 Birches, 71,600 Aſhes, 20,260 Alders, 12,000 Sycamores, 26,850 Poplars, 6000 Spruce Firs, 3,020 Laburnums, 9,080 Mountain Aſhes and 30 of lord Fife's Mountain Aſh, 7050 Norwich Maples, 20,000 Cheſtnuts, 1000 Limes, 11,000 Roans, 500 Pinaſters, and 8206 Willows of different ſorts.

There have likewiſe been planted nearly 2000 Aſh, Elm, Sycamore, Mountain Aſh and Oak, from four to

* County Reports, 4to. 1794.

five

Digitized by Google

five feet high, along the ſide of a natural Wood that borders on the highway.

In addition to the plantation on the hill of Inchorſie, including the belts on the ſide of the road leading to Rothemay, four acres and a half with 2500 Larch, 1000 Beech, Birch, and Fir, 100 Mountain Aſh and Poplar, and 200 Elm. Total 673 ½ acres, and 4,063,880 trees.

Marr Lodge in the county of Aberdeen, 300 acres incloſed, and 2000 Larches planted among the Wood naturally produced. This incloſure is now full of thriving Firs, Birch, Poplars, and Mountain Aſh. Many of the trees in the old Woods are ſix feet in diameter.

In building a bridge over the Dee, though the ſea-port of Aberdeen is not above ſix miles diſtant, yet the directors of the work were ſo conſcious of the ſuperiority of the Wood in the foreſt of Marr to foreign Wood, that they had it brought by land carriage above 100 miles, though the roads were in many places very bad.

In the county of Moray, ſince 1797, were planted twenty-ſeven acres, with 41,130 trees.

The earl of Fife has planted altogether between 11,000 and 12,000 acres.

The above account is extracted from the 6th, 15th, and 21ſt volumes of the Tranſactions of the Society of Arts, &c. where may be found many important obſervations derived from the extenſive experience of this truly patriotic nobleman.

The Earl of Breadalbane has alſo been a great planter in Scotland.

The earl of Moray, at Darnway in the county of Elgin, has planted 236,000 Oaks; 175,000 mixed trees, Aſh, Beech, Elm, Sycamore, Cheſtnut, Spruce, Fir and Larch. Between the years 1767 and 1781, 7,876,000 Scotch Firs.

George Roſs, Eſq. of Cromarty, planted 90,000 Oaks, 42,000 Aſhes, 13,000 Beeches, 4000 Cheſtnuts, 31,200 Elms, 3,005,000 Scotch Firs, 1,900 Larches, 2,100 Sycamores.

Great plantations have been made at Cullen houſe in the county of Banff, and at Monymuſk in Aberdeenſhire.

The earl of Dundonald has planted much in the moors behind Culroſs and on the Knock of Crieff in Perthſhire.

There are vaſt Fir Woods in Rannock, beſides others in Strathſpey and elſewhere in the north of Scotland.

From Dunkeld to the caſtle of Blair, twenty miles, the proſpect is diverſified by views of extenſive Woods and plantations. From Logierait to Taymouth, and even to Killin, the extent of planting is very conſiderable, eſpecially about the Earl of Breadalbane's caſtle, and on both ſides of Loch-Tay, ſixteen miles. From the houſe of Auchtertyre, by Lawers and Comrie, to the ſource of the Earn, a variety of trees has been planted, and a great extent of waſte land covered. At Gartmore, at Callander, &c. the ingenuity of art has conſpired with the beauties of nature to ornament the country with Wood.

Argyleſhire.

Great part of this county was once covered with Wood: even ſo late as the commencement of the eighteenth century, the Woods were held to be of little value. Some time after that however they were brought into greater eſtimation, by means of two Engliſh companies who ſet up iron forges. Woods vary in value from 5s. to 20s. an acre annually: they are cut at the end of nineteen or twenty years, leaving ſuch a number of Oak ſtandards as the parties agree to ſpare: they are then incloſed for ſix or ſeven years, and after that thrown open to cattle. The extent of ground occupied by natural Woods may be about 30,000 acres, but this bears ſo ſmall a proportion to the whole county, that many large tracts of it appear naked.

Of plantations there are not many, nor any of great extent except the duke of Argyle's, which may be ranked among the greateſt in the kingdom. About his Grace's ſeat at Inverary, above a million of trees have been planted, occupying many ſquare miles. Some of his plantations are in the direct face of the ſea breezes, and in the moſt expoſed ſituations, yet all thriving. There are Oaks in them from eight to ten feet in circumference, Aſhes and Planes from nine to twelve, Beeches, Elms, and Cheſtnuts from twelve to fourteen, and all in a growing ſtate. The ſmaller and later plantations in every part of the county are equally thriving, where the ſize of them is not too diminutive. At Inverneil, Firs of twenty years old meaſure three feet in circumference; and at Gartnagrenach ſome of thirty-five years old, planted in a natural Wood, meaſure from five to ſix, though ſtanding on barren rocks. The ſoil, climate, and ſituation of this county are remarkably well adapted to planting and raiſing timber; the ſoil being generally dry, the climate warm and moiſt, the ſituation almoſt every where commodious for water carriage, and the ſurface ſo uneven that every part of it abounds with ſhelter. If trees be planted thick enough and in large maſſes, there is hardly any ſituation in the county ſo untoward as to prevent their growing. The grounds planted by the duke of Argyle, being moſtly a barren heath, were not worth above 50l. a year, forty years ago. A million of trees, at 2s. 6d. each, would amount to 125,000l[p].

Clydeſdale.

There are ſcarcely any ſpontaneous coppices above the uppermoſt fall of the river; but ſome of the principal landholders, of late, have done much to adorn the country with planting. In the early part of the 18th century, except a few trees about ſome of the houſes, this part of the country was quite naked. There are now about 1800 acres planted, three-fourths of which at leaſt has been done in the laſt twenty years. The trees of various kinds, but the Scotch Pine and the Larch are the moſt prevalent. From the top of the falls downward, coppices ariſe every where, conſiſting of Oak, Aſh, Birch, Elm, Alder, Holly, Gean, or Wild Cherry, Sallow, Hazel, &c. Of theſe there are 760 acres in the lower part of the upper ward, beſides 580 acres of planted Wood, making the whole in this tract 3140 acres. In the middle ward there are 1350 acres of coppice, and 2850 acres of planted Wood. There are few coppices and little planted Wood in the under ward. Hedgerows and narrow ſtripes ſurround the ſmall incloſures and give the country a clothed appearance, but probably the ſquare contents do not exceed 700 acres. This makes the whole of the Woods 7,990 acres; but there is reaſon to believe that there are now conſiderably above 8000 acres.

The coppice Woods are ſometimes cut in twenty-five or twenty-ſix years, but are more frequently allowed to grow thirty years. An acre is ſold at from 20l. to 30l[q].

Dumfries-ſhire.

There are many extenſive, beautiful and valuable natural Woods in this county, eſpecially in the Nithſdale diſtrict, and alſo many large and delightful plantations around the ſeats of the noblemen and gentlemen. Much attention is paid to the preſervation and rearing of the Woods by the proprietors in general. The low and ſheltered ſituation of this county, eſpecially the Nithſdale diſtrict, which is completely ſcreened from the ſea blaſt by the Galloway hills, is remarkably favourable to the growth of trees.

Many of the natural Woods have been cut within the laſt thirty years. In general the ſtools were completely fenced, the blank ſpaces filled up with young plants, and the Woods weeded (thinned) at the proper ſeaſons. In the laſt twenty-four years many extenſive and beautiful plantations have been made[r].

County of Fife.

There are ſome patches of natural Wood in Fife, but they are few and inconſiderable. The Wood growing round the manſion-houſes of proprietors is moſt aged and valuable, conſiſting of Aſh, Elm, Beech, Fir, Lime, and ſome Oak. Thoſe plantations belonging to the earls of Crawfurd and Leven are the largeſt.

Several, leſs extenſive, have been raiſed in different parts, particularly on the north ſide by the proprietor of Rankeiler, and Mr. Gourley of Craigrothric; and on the ſouth, on the eſtates of General Wemyſs, Sir James Sinclair Erſkine, and Mr. Ferguſon of Raith. Theſe are now in an advanced ſtate.

Several tracts of barren ground, and divided commons, have been lately planted: but as the trees are yet in an infant ſtate, they make little appearance: they conſiſt of Oak, Scotch Fir, Larch, Beech, Birch, Aſh, &c. Larch is in higheſt repute, as it agrees with almoſt any ſoil; the Wood is very valuable, and its growth rapid [t].

Eaſt Lothian.

Along the coaſt there is hardly any thing that deſerves the name of planting: but the vale of Tyne, within theſe fifty years, has become ſomewhat better clothed with Wood. In the higher diſtrict of the county, adjoining to the hills of Lammermoor, there is ſtill more planted Wood, the oldeſt of which, upon the Tweddale eſtate, conſiſting principally of Oak, is ſuppoſed to have been planted during the uſurpation of Cromwell. There are alſo ſome Woods upon that eſtate, which tradition ſays were planted about the time of the revolution, conſiſting of Oaks, Beech, Elm, Aſh, and Scotch Fir.

The Beech ſeems no where in Scotland to be of an older date than the revolution, but it thrives wonderfully.

Upon the eſtate of General Fletcher of Salton, and of Mr. Brown of Coalſton, and ſome others in that diſtrict, there are copſe-woods compoſed of the dwarf or Scotch Oak, the Hazel, Birch, and other indigenous trees, which evidently ſeem to be a remnant of that ſpecies of copſe which we are told in early times covered the greater part of the ſouth of Scotland. The only Wood, properly ſpeaking, to be found in the lower part of this county, is at Tynninghame, which was begun to be planted about the beginning of the 18th century by Thomas, the ſixth earl of Haddington; and it grows down to the ſea beach, upon a light ſandy ſoil.

The Larch has been planted in this county within theſe laſt thirty years, and is more rapid in its growth than any tree we have except the Huntingdon Willow. But the climate of the low part of this county is in general too dry for trees, and they do not grow well, unleſs the bottom is low, and has a tendency to moiſture [u].

Mid-Lothian.

There may be perhaps about 5000 acres occupied by natural Wood and plantations; the former only on the banks of a few rivulets, the latter round every gentleman's ſeat in the county. Oak in many places is very flouriſhing: Elm and Aſh never fail to thrive, and as well as Oak find a ready ſale. Beech and Plane (Sycamore) are moſt luxuriant, but not much valued as timber. The Scotch Fir is much cultivated, but neither grows large, nor is the Wood much eſteemed. The Larch ſucceeds beſt of the Fir kind, next the Silver Fir; but the Spruce Fir ſoon becomes ſtunted, and worth even leſs than the Scotch Fir. Foreſt trees planted in hedgerows come to no good. A thin belt of four or five rows will not ſtand the climate; there ſhould be twenty rows at the leaſt [v].

Perthſhire.

The Highlands of Scotland, was at one period underwood, but it was gradually baniſhed into the ſteep declivities of glens, or among rocks, &c. deemed incapable of cultivation. About the beginning of the 18th century Woods began again to claim ſome attention. For fifty or ſixty years back, the poſſeſſors of ſome eſtates in this county thought of repairing the devaſtation which had formerly been permitted or encouraged on the growing timber. Within theſe laſt thirty years plantations have increaſed rapidly both in ſize and number. In the Stormont, in Athol, in Breadalbane, in Stratherne, in Strathallan, in the Carre of Gowrie, in the vicinity of Culroſs, in Monteath, in almoſt every corner of the county, there are thriving plantations, which conſiſt of a variety of foreſt trees, adapted to the nature of the ſoil, which do honour to the ſpirit and judgment of the owners. In former times a few favourite trees might be ſeen about the reſidence of a great man, ſome of which may have ſtood for centuries, and become venerable by their years, but the ſcale has become greatly enlarged in this part of the empire, beyond all example at any period or in any age.

The Scotch Fir is the moſt common in theſe plantations. The Larch has many years ago been introduced into this county. There are Larches at the caſtle of Blair, Athol, and Dunkeld, planted fifty years ago, which meaſure full eight feet in circumference, at five feet from the ground, and others of as luxuriant growth at Taymouth. But the largeſt in this county are at Monzie, which meaſure five feet in diameter. At Blair Drummond, Gleneagles, Roſſie, &c. are trees of a great ſize.

Natural Fir Woods are very frequent in the north of Scotland, but are rare in this county. The family of Struan Robertſon however has time immemorial drawn a conſiderable revenue from the Fir-wood on that eſtate, which grows naturally on the ſide of Loch Rannoch. Theſe Woods cover 2566 acres, and form the moſt extenſive foreſt in one continued tract, which is to be found in this county. His detached Woods of Oak, Birch and Alder cover 3869 Acres.

There was a conſiderable tract of natural Fir ſeveral years ago near Tyndrom on the eſtate of Breadalbane, but at this time there remain only a few gleanings. Natural Firs are growing in one of the parks of Finlarig on the ſame eſtate, and in ſome other parts of the county; but all theſe are on a ſmaller ſcale.

There are more Oak Woods and of greater value in this county than in all the reſt of Scotland. Oak coppices are cut once in twenty-four or twenty-ſix years. A few trees of the moſt promiſing appearance are left at proper diſtances, from one cutting to another, and ſometimes for three or four cuttings. The barbarous cuſtom of throwing them open to cattle at the expiration of five, ſix, or ſeven years is ſtill continued.

Some thouſands of acres which had been planted with Scotch Firs, upon ſuppoſition of their being incapable of cultivation, have lately been cleared, and let at a progreſſive rent, in ſome caſes amounting to 20s. the acre. Betwixt Coupar and Perth, a tract of thirteen miles, the plantations on 2000 acres, on both ſides of the public road, have been grubbed up; and the operation is ſtill going on, both there and in other places [x].

Roxburghſhire.

The natural Wood in this county is at leaſt 608 acres, and the number planted is nearly 4682; beſides hedgerows, ſtraggling trees, and tufts around villages and farm houſes. In ſeveral places, particularly at Ancrum, a number of trees were felled of a large ſize about thirty years ago; and there are now on that eſtate ſeveral trees from ten to thirteen feet in circumference. Many trees equally large ſtill remain, in different parts, untouched by the axe or the weather. From poverty of ſoil or injudicious management, ſeveral hundred acres, planted ſome time ago, chiefly with Scotch Firs, have totally failed; and nearly as many, lately planted; do not promiſe well. Of the trees commonly cultivated, the Beech, the Plane (Sycamore) and the Lime, are the moſt luxuriant and beautiful; the Aſh and Scotch Fir are the moſt profitable. A number of Larches are coming forward in different places. Fir produced in the county has been tried with ſucceſs for joiſts and ſpars. Towards the beginning of the 18th century, Sir William Bennet, Sir —— Elliot of Stobs, Mr. Douglas of Cavers, Mr. Elliot of Wells, and Mr. Bennet of Cheſters, made large plantations of Firs, from which their deſcendants have reaped great advantage. Theſe are now moſtly cut down; but others, planted only a few years after them, are now (1798) on ſale at Wells and Stewartfield; and there is

[t] County Report, 8vo. 1800. [u] County Report, 4° 1794.
[v] County Report. 8vo. 1795. [x] County Report, 8vo. 1799.

Digitized by Google

every appearance of twenty or thirty acres being equally ready every year for half a century. Much land has been lately planted, and in a manner which bids fairer for ſucceſs than any that was formerly followed.

Selkirkſhire.

The greateſt part of the Wood in this county conſiſts of Scotch Firs, the largeſt half of which was planted twenty-five years ago.

Several hundred acres however are occupied by other trees more valuable though of ſlower growth, as Oaks, Aſhes, Elms, and Planes, (Sycamores); many of which have been lately planted, though not a few are of a great age and a large ſize[7].

From this very imperfect account it will be ſeen that Scotland is by no means ſo deſtitute of trees as has been repreſented by ſome prejudiced perſons; and that a great ſpirit of planting has ariſen in ſome parts which would do honour to England. The Earl of Fife has not only planted to a very conſiderable extent; but he has beſtowed his own perſonal attention upon his fine plantations; and has even ſecured them to poſterity, that they may not be immaturely deſtroyed, but felled when the trees may be of moſt advantage to the proprietor and the public.

Upon the whole it appears that a ſpirit of planting has ariſen towards the end of the 18th century in ſeveral parts of the country, which will furniſh a ſupply for all rural uſes. As to timber for the navy, little is to be expected from theſe plantations, both becauſe the proportion of Oak is ſmall in moſt of them, and it is very improbable that many of the trees will be ſuffered to arrive at an age and ſize adapted to this purpoſe. Naval timber muſt either be raiſed in the Royal Foreſts, or be procured by great encouragement held forth to private perſons. Some idea may be formed of the prodigious quantity of Oak timber that is conſumed by the navy, when we conſider that a ſeventy-four gun ſhip ſwallows up 3000 loads of fifty cubical feet each; conſequently it takes 2000 large well-grown trees, of nearly two tons or forty feet each; that is the produce of fifty acres[8].

Price of Timber, Bark, Coppice Wood, &c.

Price of Oak in 1608, 10s. the load.
——— 1664, 13s. 4d. the ton in general.
——— 15s. the ton for the navy.
——— 1663 } Straight and compaſs timber
——— 1665 } for the navy, 2l. to 2l. 15s. 6d. the load.
Knee timber, 2l. 15s. to 3l. 2s. 6d.
——— 1756 Straight and compaſs timber 3l. to 4l. 5s.
Which has continued ever ſince.
Price of Bark, time of James I. 2s. the cart load.
——— now 50s. to 3l. the coppice load, weighing from 7 to 11 cwt.

Increaſe of the price of Oak Timber in 1792, *within the laſt forty years.*

Bedfordſhire, increaſed about 3d.
Cambridgeſhire, increaſed 20 per cent.
Cornwall, increaſed about one-third.
Derbyſhire, near double.
Eſſex, increaſed from 1s. 3d. to 1s. 8d.
Hampſhire increaſed from 30s. to 3l. a load for carpenters.
Hertfordſhire increaſed from 45s. to 65s. or 75s. a load for carpenters, who buy by round cube meaſure, and ſell by ſquare cube meaſure at 3s. gaining 120 per cent.
Kent, increaſed one-third.
Lancaſhire, double.
Lincolnſhire, increaſed 8d. for carpenters, large timber more.
Nottinghamſhire, Oxfordſhire, } increaſed at leaſt one-third.
Rutlandſhire, increaſed one-third or ſomething leſs.
Shropſhire, increaſed one-third.
Suffolk, accounts various; increaſed 100 per cent, or one-ſixth.
Suſſex, increaſed one-third; 100 per cent in twelve years.
Warwickſhire, little difference.
Worceſterſhire, increaſed at leaſt one-third.
Yorkſhire, accounts various—more than double—not much increaſed—increaſed one-fourth, or nearly one-half.
Montgomeryſhire, doubled.
Brecon, increaſed 50 per cent.—or 20s. to 40s. the ton.
Caermarthenſhire, increaſed more than three times.
Pembrokeſhire, increaſed at leaſt one-third, perhaps one-half.
Radnorſhire, increaſed at leaſt 50 per cent.
Mid-Lothian, increaſed 40 per cent within ten years[9].

Price of Timber, &c. at the end of the 18th century, from the Surveys of Counties addreſſed to the Board of Agriculture, and other authentic documents.

Bedfordſhire. See Huntingdonſhire.
Berkſhire. Large Oak, Aſh and Elm 1s. 6d. a foot; Beech and Sycamore 1s. Oak bark 6l. to 10l.
Cambridgeſhire. Oak bark rated at 25 per cent. on the value of the timber.
Devonſhire. Oak 40s. a ton for carpenters uſe, 50s. to 3l. for coopers.
Coppice Wood (1794) 15l. an acre, at twenty years growth.
Cordwood 10s. a cord (4, 4 and 8) or 6d. the hundred weight.
Dorſetſhire. Oak 1s. 6d. a foot, or 3l. 10s. a load of forty feet, including tops and bark. Elm and Aſh 9d.
Eſſex. Oak 2s. a foot, top and bark included, the buyer felling.
Coppice Woods (Aſh, Sallow, Hornbeam, Hazel, and Thorn) worth 8l. an acre at the ſtub.
Glouceſterſhire. Cordwood 10s. 6d. or 11s.
Some Coppices ſold in 1792 at 15l. an acre. Bark 5l. 10s.
Oak 1s. 3d. a foot.
Herefordſhire. Coppice Wood from 12l. to 22l. an acre, from twelve to fourteen years growth.
Hertfordſhire. Oak 3l. 10s. a load, worth at the yards 5l. 10s.
A good plant of thriving underwood may be averaged at 20s. an acre annually.

Huntingdonſhire.—It is cuſtomary in this county and its neighbourhood to ſell Oak timber before it is felled. The value is from 20d. to 2s. 6d. a foot, according to its quality, at the ſame time taking into account the heads, which are included in the above prices: the purchaſer pays for felling; ſo that the average price may be about 2s. 3d. a foot, including the heads.

The cuſtomary mode of ſelling Oak bark, is by ſo much money in the pound, according to the value of the timber. The average price is about 8s. in the pound.

The value of Elm timber is 14d. per foot; and if very good as high as 16d. But this price does not include the heads.

Ordinary Aſh is ſold at 15d. a foot; but if it is fit for the cooper's uſe, it is worth 20d.

The method of ſelling underwood is general throughout this and the adjoining counties. It is felled into dozens (meaning twelve ſquare poles) and ſold on an average for about 12s. a dozen or 1s. per pole. Some dozens are eſtimated as high as 20s.; inferior ones at 10s. and ſome as low as 6s.

Kent. Underwoods cut from ten to fourteen and eighteen years growth from 5l. to 15l. an acre, hop-poles the chief article. Winter kiln bavins 6s. a hundred; ſummer ditto 8s. or 9s.; houſehold ditto 12s. or 14s. all ſix feet long and two round. Buſhes from 7s. to 10s. a load of fifty bundles. Beech 7d. or 8d. a foot for fellies, for axle-trees 10d. Cordwood 12s. to 16s. (14. 3. 3½.)

[7] County Report, 8vo. 1798. [8] Marſhall's Planting, 1, 111, ed. 2.

Lincolnſhire. Oak for fencing, &c. 1s. 6d. for building nearly double. Aſh and Poplar 1s. Scotch Fir 8d.

Norfolk. Oak in 1782, 3 guineas to 3l. 15s. a ton. Top-wood 7s. to 12s. each load. Timber in the rough 15d. to 20d. Aſh ſtanding, 40s. to 50s. a ton; or 9d. to 1s. a foot.

Northamptonſhire. Oak 1s. 4d. to 2s. 6d. a foot.
Aſh 10d. to 1s. 6d.
Elm 9d. to 1s. 4d.
Poplar 6d. to 1s.
Bark 7s. to 12s. in the pound of the value of the tree.
Underwood (eleven to fourteen years growth) 6l. an acre.

Northumberland. Oak 2s. to 3s. the foot.
Aſh and Elm 1s. to 2s.
Oak bark 9l. a ton, in 1793.

Rutlandſhire. Beſt Oak 2s. 6d. the foot.
Underwood, 3l. to 6l. an acre.

Shropſhire. Bark 20s. a ton.

Somerſetſhire. Oak timber from 50s. to 3l. 16s. a ton.
Aſh from 45s. to 3l.
Underwood, at eighteen or twenty years, 16l. an acre.

Suſſex. Good Oak 6l. a load.
Beech 3l. 6s. 8d.
Aſh 3l. 15s.
Elm 2l. 10s.
Bark in 1792, 19l. in 1793. 14l.

Warwickſhire. Oak 3 guineas to 3l. 10s. a ton.
—— bark 25s. to 40s. a ton.
Underwood 3l. to 8l. an acre.

Weſtmoreland. Coppice Wood (ſixteen years growth) 10l. to 15l. an acre—if Oak, 20 guineas, 6l. for charcoal, and 15l. for bark.

Wiltſhire. Oak 1s. to 1s. 6d.
Aſh 9d. to 1s. 6d.
Elm 9d. to 1s. a foot, in the rough.

Yorkſhire. Eaſt Riding. Good Oak 2s. to 2s. 6d. common 1s. to 1s. 6d.
Good Aſh 1s. to 1s. 6d. common 8d. to 1s.
North Riding. Oak 3l. a ton, or 1s. 6d. a foot delivered in the yard—for the carpenter 1s. 4d.
Aſh 1s. to 1s. 6d.
Chopt bark 10s. 6d. a quarter.

Scotland.

Clydeſdale. Coppice Woods, at twenty-five, twenty-ſix or thirty years growth, 20l. to 30l. an acre.

Fir	9d.
Oak	1s. 8d. to 2s. 0d.
Aſh	1s. 6d. to 2s. 0d.
Elm	2 0
Sycamore	2 0
Beech	1s. to 1 6
Sallow fit for mill-timber	2 6
Lime	1 4
Poplar, moſtly white	1 4
Birch	1 0
Holly for veneering, very rare	5 0
Gean tree	1 6
Pear and Apple	1 6

Roxburghſhire. Oak, Aſh, and Elm 1s. 8d. to 2 0
Beech and Plane (Sycamore) 10d. to 1 2
Fir 7d. to 1 0
Red Saugh or Sallow 1s. 6d. or 1 8

The annual growth of Trees, and ſize of Timber at different ages.

The growth of trees varies much according to the age, ſoil, and other circumſtances. Some eſtimate however may be made of it, by comparing a great number of accounts. Such as could be readily obtained are ſet down.

Mr. Barker has given a ſeries of obſervations on this ſubject in the Philoſophical Tranſactions, vol. 78. for 1788.

Except the two firſt Aſh trees, Mr. Barker remarks, that he finds the growth of Oak and Aſh to be nearly the ſame. The common growth of both is about an inch in girth in a year; ſome thriving ones will grow an inch and half: in general the thriving ones were meaſured.

Great trees grow more timber in a year than ſmall ones; for if the annual growth be an inch, a coat of one-ſixth of an inch is laid on all round, and the timber added to the body every year in its length multiplied into the thickneſs of the coat, and into the girth, and therefore the thicker the tree is, the more timber is added. The body of No. 9. was nine feet long, the girth under the bark above thirteen feet, the thickneſs of the coat one-ſixth of an inch, or $\frac{1}{72}$ of a foot: then $9 \times 13 \times \frac{1}{72}$ is one foot and ſix-tenths of timber added in a year to the body, beſide the increaſe on all the branches, and it had a very great head; one limb ſquared twenty inches, and is itſelf equal to a moderate tree.

The hedge in which No. 4. grew was planted in 1665, probably the tree is not older than that year; it has therefore increaſed in girth about 1. 3 inch every year ſince it was ſet.

The Oak No. 5, ſeems to have ſowed itſelf: Mr. Barker did not know of it till about the year 1740, when the hedge being cut, the tree was found, and might be then twenty years old or more.

The two Aſh trees No. 20 and 21, grew much faſter than any of the reſt, but were neither of them handſome growing trees. No. 20 had ſeveral ſeams where the bark parted from the Wood, and were likely to be dead ſides. No. 21 was about as thick as a walking-ſtick in 1730. It did not grow round and ſmooth, had no dead ſide, but ſeveral deep furrows in it; ſo that theſe two trees ſeemed to grow faſter than they could grow well.

Digitized by Google

In 1733 No. 23 was about as thick as a pitch-fork ſhaft.

The Elm No. 37 was planted with the quick in january 1756, and cut down to the ground as that was. It is a kind of Witch Elm, which grow faſter than the upright ones, and with great round heads. No. 38 was ſo far like a Witch Elm, that at ten feet high it parted into a great head, but it grew much ſtraighter and handſomer than that kind of tree generally does.

Planted trees at a diſtance from the hedge ſeem not to grow ſo large as ſown trees in the hedge; whether from the check the trees receive in tranſplanting, or that the trees not in hedges are more rubbed by the cattle; perhaps both cauſes concur when the trees are tranſplanted large; but trees ſet in quicks, when very ſmall, do not ſeem to be hurt by it. Some Oaks were ſet with the quick, and a row of acorns was ſome years after ſown againſt it; but in between forty and fifty years they have not overtaken the planted ones in ſize; the ſown ſeem however to be taller trees than the planted.

It is a general opinion, ſays the biſhop of Landaff, in this, and I believe in other countries, that it is more profitable to fell Oak Wood at fifty or ſixty years growth, than to let it ſtand for navy timber to eighty or one hundred. According to the price which is now paid by the Navy-board or the Eaſt India Company, the opinion ſeems founded in truth.

If profit be conſidered, a tree ought to be cut down and ſold, when the annual increaſe in value by its growth, is leſs than the annual intereſt of the money it would ſell for. This being admitted, we have only to inquire into the annual increaſe in the value of Oaks of different ages.

In the Philoſophical Tranſactions for 1759 there are ſome uſeful tables reſpecting the growth of trees by Mr. Marſham: from theſe the two following inferences may be drawn. 1. That it is highly profitable to let young thriving Oaks, which are not worth above 30s. a tree, continue ſtanding. 2. That it is not profitable to let Oaks of eighty or one hundred years growth, continue ſtanding.

Three Oaks marked in the tables No. 8, 11, 12, in april 1743, before they began to ſhoot, contained eleven and one half feet of Wood, and were altogether worth, at eighteen pence a foot, bark included, 17s. 3d.

The ſame trees, ſixteen years afterwards contained thirty-four and one-half feet, and were worth 2l. 11s. 9d. Now if 17s. 3d. had been improved at the rate of ſeven per cent. at compound intereſt for ſixteen years, it would not have amounted to 2l. 11s. 9d.; and of conſequence the proprietor, by letting ſuch Oaks ſtand, improves his property in as high a degree, as if he put out this money to intereſt at near ſeven and a half per cent.

Three Oaks, No. 2, 3, 5, in 1743 contained 102½ feet of timber, and were worth 7l. 10s. 9d. The ſame trees ſixteen years afterwards, contained 132½ feet, and were worth 9l. 18s. 6d. Now the value of the trees in 1743, improved at the low rate of intereſt of two per cent. would, in ſixteen years, amount to a ſum exceeding 9l. 18s. 6d. The proprietor, then, by letting ſuch trees ſtand, does not improve his property at the rate of 2l. per cent.

The Oak, No. 1, in the third table, was worth 1l. 2s. 6d. in 1757, it gained in one year one foot, or 1s. 6d. in value; if it had been worth 30s. and had gained one foot, there would have been no profit in letting it ſtand, as the intereſt of 30s. at five per cent. would have produced 1s. 6d. in the year. It is for this reaſon that 30s. is fixed upon as the value of trees which ſhould be cut down. It muſt not be ſuppoſed however that great preciſion can attend this obſervation, ſince particular ſoils, or the greater or leſs thriving condition of the Wood, may render it uſeful to cut down trees before they are worth 30s. or to let them ſtand a while longer. It ought to be remarked alſo, that large trees ſell for more per foot than ſmall ones do, yet the uſual increaſe of price is not a compenſation to the proprietor for letting his timber ſtand to a great age. This may be made out from the following experiment: on the 27th of october, 1792, was meaſured, at ſix feet from the ground, the circumference of a very fine Oak of eighty-two years growth, and found to be 107 inches; on the ſame day of the month, in 1793, it meaſured 108 inches. There is not one Oak in fifty, at the age of this, which gains an inch in circumference in one year. The length of the boſt or this tree was about eighteen feet; it contained about eighty-four feet of timber, and was worth, at 2s. a foot, twelve guineas. It gained in one year very little more than a foot and a half of timber, or 4s. 6d. in value; but the intereſt of twelve guineas at four per cent. amounts in one year, to above twice the value of the increaſe, even of this tree, which is a ſingularly thriving one.

I have been more particular, ſays the learned biſhop, on this ſubject, from a public conſideration. Many men are alarmed leſt our poſterity ſhould experience a ſcarcity of Oak timber for the uſe of the navy; and various means of increaſing its quantity have been recommended with great judgment. In addition to theſe means, the making a much greater than the ordinary increaſe of price on timber of a large ſcantling, might be not improperly ſubmitted to the conſideration of thoſe who are concerned in the buſineſs. If the Navy-board would give 8l. or 9l. a load for timber trees containing one hundred cubit feet or upwards, inſtead of 4l. or 5l., every man in the kingdom would have a reaſonable motive for letting his timber ſtand till it became of a ſize fit for the uſe of the navy; whereas, according to the preſent price, it is every man's intereſt to cut it down ſooner[b].

In a fall of Oak timber in lord Bagot's Woods, Mr. Marſhall counted the rings of one which was round at the butt. The number about 200; but the laſt forty or fifty years growth were ſo thin, that he could not count them with certainty, though with ſufficient accuracy to ground the following calculations.

The girt of this tree, in the girting place, was nine feet, the diameter of which is ſomewhat more than thirty-four inches. The eſtimated growth in this part is thirty inches diameter, during the firſt 150 years, and four inches (two inches thick) in the laſt fifty years. The length of the ſtem twenty-two feet. The contents of the whole 110 feet of timber. The contents of the firſt 150 year growths eighty-five feet; leaving twenty-five feet for the growth of the laſt fifty years. Therefore although the increaſe of diameter has been comparatively ſmall during the laſt fifty years, the increaſe of timber has been nearly as great as in the firſt ſtages. But ſuppoſing this tree had been taken down at 150 years old, it would, at 2s. a foot, have produced 8l. 10s.: the intereſt of which would have amounted, in the courſe of fifty years, to more than 20l.; beſide the uſe of the land, during that time. Whereas the tree, at that rate, is now worth only 11l.

Theſe calculations and inferences are not intended to excite a ſpirit of felling timber prematurely, but to aſcertain the proper age of felling; it being worſe in point of economy to ſuffer timber to ſtand too long, than to cut it down before it has attained its full growth.

The proper ages of felling appear to be—for Poplar from thirty to fifty years old; for Elm and Aſh from fifty to a hundred, and for Oak from one hundred to two hundred. Very much however depends on ſituation, as well as on the ſoil and ſubſoil in which the trees are rooted. On dry abſorbent ſoils, the Oak and Elm at leaſt are obſerved to go off much ſooner, than on ſuch as are cool and retentive[c].

Three remarkably thriving Elms, thirty years old: two of them more than two feet diameter at the butt; and meaſure at four feet high more than eighteen inches. Not bigger than eight more left ſtanding; meaſure forty-four feet including bark: above forty feet of ſaleable timber, worth 1s. a foot 2 0 0
16 fencing-poſts and rails, at 4d. - 0 5 4
9 feet of cordwood, at 10s. - - 0 11 4
40 ſpray faggots - - - - - - - 0 3 4
£. 3 0 0

Some hedge-row Elms 110 years old, were from two and a half to three feet in diameter. Some of theſe evidently overgrown, though in a well-ſoiled cool ſitu-

ation. Elms therefore can ſeldom ſtand, with economy, more than 100 years [d].

Elm grows with uncommon luxuriance in the vale of Gloceſter. Its progreſs is quickeſt on the ſlighter warmer lands; but here the trees ſooneſt decay, and the timber is of the leaſt value. In clay its growth is leſs rapid, but the timber is of a much better quality: the colour of iron; and in ſome inſtances almoſt as hard. The Briſtol ſhip-builders have a ſupply of keel-pieces from this quarter [e].

The rings in a full-grown Aſh, meaſuring twenty-one inches in diameter, were ninety. Of the firſt and laſt ten years the growth had been ſlow. In the intermediate years, the different thickneſſes of the rings, in different years, were ſtriking.

The number of rings in another Aſh, eighteen inches in diameter, were, very diſtinctly, 112. Theſe Aſhes, on a cool retentive ſubſoil, were full grown, and many of them overgrown, at 100 years old. It is not ſolidity, but toughneſs, which is wanted in Aſh Timber, and toughneſs is a quality of youthful growing trees. It is probable therefore that Aſh, for the uſes of huſbandry, ſhould not ſtand 100 years. The Aſhes in this wood (Statfold) were in general from forty to fifty feet in the ſtem.

It is a good practice to fill up the vacancy of an oak wood with Aſh; their upward growth being more rapid than that of the oak, and their ſuperiority of value conſiſting in a ſtraightneſs and length of ſtem [f].

In a common Poplar that had fifty rings, the diameter at the butt was two feet three inches, at ten feet high twenty-four inches. In the laſt ten years its increaſe had not been more than three inches in diameter, or an inch and half in the width of the rings. It had therefore grown ten inches and a half in the firſt forty years; or a quarter of an inch each year. This tree was beginning to rot at the heart; in the lower part of the ſtem, about an inch and half in diameter was entirely decayed; it had therefore ſtood too long, though to appearance it was a healthy thriving tree. Even ſuppoſing it to have fallen perfectly ſound, the increaſe for the laſt ten years was inadequate to its encumbrance, and the intereſt of its value at forty years old; at which age it would have paid well for planting and land-room. The ſoil a rich loam: the ſituation moiſt [g].

Horton Wood is in a flat ſituation, the ſoil ſhallow, with a clay bottom; but very proper for the growth of oaks. It is a large wood, of about ſeventy years ſtanding; the trees tall and ſtraight, but in general not ſufficiently furniſhed with ſide branches, without which a tree ſeldom comes to any conſiderable girth. If oaks are permitted to ſtand near together, longer than is neceſſary to ſet them in a fair way for attaining height, they will not puſh out thoſe arms furniſhed with leaves which are ſo eſſential to form a fine trunk. From twelve to fifteen yards is as near as they ought to remain, after the laſt thinning.

The generality of the oaks have gained from half an inch to an inch in girth. An inch gains a pretty fair profit.

Heath Wood is an indifferent ſoil, ſloping to the north. It is ſix acres, and eighty years growth.

Moole Grove is a ſound good ſoil, ſixty years growth [h].

Mr. Harries afterwards informs us, that he meaſured ſome of the trees the year following (1786) and from the prodigious quantities of inſects, which almoſt eat away the leaves of the oaks, and the uncommon drought of the ſummer till auguſt, he found that the oaks in Heath Wood had not gained, upon an average, more than a third of an inch in circumference. In another grove of oaks, that nearly eſcaped the ravages of inſects, he found the increaſe an inch upon an average. A tree four feet round, that has timber twenty feet in length, gains thus a foot of timber, worth 1s. a foot at leaſt, and pays 5l. per cent for ſtanding. His Poplars gained near two inches, and the two Elms as much.

Mr. Harries experienced the Larch to be of the quickeſt growth, and the moſt valuable wood of the reſinous trees. But unleſs there is good room for the lower branches, the trees will not arrive at any conſiderable ſize. And this, he ſays, ſhould be obſerved in the early ſtage of all trees of a pyramidical form. They may perhaps ſtand for timber at the diſtance of about ſeven yards. The Scotch Fir may be planted between them, which may be thinned out when the branches obſtruct the Larch. He meaſured ſeveral Larches that had been planted about thirty years, from four to five feet ſix inches round, at five feet from the ground; and ſpeaks of one, which in twenty years was ſix feet in circumference [i].

* Circumference 8 inches.

† Circumference 10 inches.

The circumference in the above table was taken at five feet from the ground. It appears that the old trees grew very differently in different years; and that 1783 and 1784 were favourable to their increaſe. The Larches, among all the trees which have been planted, amounting to near 400,000, have upon the whole ſucceeded much the beſt; have outgrown all the firs; and have done equally well in whatever ſoil they have been tried.

The Aſh No. 6. growing in good garden loam not dunged, ſix feet one inch high, and one inch and a half in circumference, april 26, 1779, was on may 21, ſeven feet eight inches high; and on june 21, ſeven feet ten inches. July 16 it was the ſame. The great growth of it therefore was in may, when it grew one foot ſeven inches; whereas in june it increaſed only two inches, and in the following month not at all. That it grew only in the ſpring, appears from the height taken april 26, 1780.

The Oak No. 17, ſix feet ſix inches in height, april 26, 1779, on may 21, was ſeven feet one inch; june 21, ſeven feet two inches; july 16, eight feet five inches. Hence the Oak has two periods of growth, the ſpring and midſummer; the latter much the moſt conſiderable [k].

Mr. Young meaſured ſeveral trees in Marquis Townſhend's extenſive plantations about Rainham: as an Oak near the houſe, of great age, that meaſured in january 1785 twelve feet eight inches and an half in circumference, at five feet from the ground, and holding its ſize very high, being large for ſixty feet. There are not leſs than eight loads of timber in it. The trunk ſeems to increaſe, though the top and branches are decayed; for Marquis Townſhend, ſeveral years ago, put a bench round it, which was quite clear of the tree, and they now join. Eight years after, Mr. Young meaſured it again, and found it to have increaſed three inches.

A beautiful Aſh, called Lady Townſhend's, not far from the Oak, was in 1785, ten feet one inch in circumference at five feet from the ground; ſtraight as an arrow, and about thirty-five feet to the firſt fork. Eight years after it meaſured ten feet ſeven inches.

Larch of ſixteen years growth, in the twelve-acre plantation, fifteen inches and a half in circumference, and fifteen to twenty feet high. In another plantation of twenty-one years growth, two feet three inches in circumference.—In one of twenty years, ſpruce fir three feet, oak two feet, larch two feet eight inches, and another of the ſame age, four feet. The firſt large larch on the right hand entering the plantation called Drozier's belt from the houſe, two feet eleven inches. Theſe meaſures were taken in 1785.

In the plantation by the bench oak, a beech one foot eleven inches; an oak one foot ten inches, another one foot ſix inches, a third two feet two inches and a half.

Three oriental Planes together, one ſeven feet, a ſecond eight feet one inch; another alone nine feet eight inches; a Sycamore by the iron gate, ten feet at four feet ſix inches above the ground, there being a knot at five feet. Theſe meaſures taken in 1793 [l].

Meaſurements taken by MARQUIS TOWNSHEND *in* 1785, *in ſome of his own plantations.*

Firs,

Digitized by Google

Firs, containing in each tree, upwards of two loads of timber. The Spruce Firs produced as good white deal as any imported from Norway, Chriſtiana, or Gottenburgh. The beſt floor in Sir Frederick Evelyn's houſe, is laid with his own Scotch Fir. What Firs have been ſold at Wootton Place have fetched nine-pence a foot. The plantations at Payne's hill having been thinned, chiefly of unthrifty or unhandſome trees, they meeted at ten feet a tree, and ſold at ſix-pence a foot. The age of theſe was about forty years; thoſe at Sir Frederick Evelyn's 100 or 120. The value per acre at Payne's Hill cannot be eſtimated in general at more than five ſhillings.

In the ſame pariſh of Cobham, and in the ſame kind of ſoil, Thomas Ruggles, Eſq. by whom the above account is given, incloſed ſeven acres in the year 1779; he ploughed it once in the ſummer, and having deſtroyed the heath and furze, planted two acres of it in november with Scotch Pine and Larch; the plants were furniſhed by a neighbouring nurſeryman, who warranted 1200 trees on an acre alive at the end of two years: the reſt he filled up with the ſame kind of trees from his own nurſery, except about an acre in the middle, which was planted with birch only. Two acres remained unplanted till 1783, by which time the land was again completely covered with heath and weeds. Shallow holes were then opened, and the trees planted in them, without any other preparation. Of thoſe planted by contract about half died, and were replaced by the nurſeryman; of his own not a ſcore: the former were ſix year old plants, two removes from the ſeed-bed; the latter four years old, one remove from the ſeed-bed. Some of the larches in this plantation are now (1785) fifteen feet high or more; the Scotch Pines about twelve or thirteen feet. Theſe are the moſt even plants; and ſome of the larches are moſſy. In other plantations, which are a few years older, Weymouth Pines and ſome Spruce Firs are mixed; but the Larch and Scotch Pine are much the moſt thrifty plants. The ſame gentleman, who has paid an exemplary attention to planting, and various departments of agriculture, in the year 1762, planted ſeveral acres with the Scotch Pine, four years old, one remove from the ſeed-bed, on an eſtate of his at Finchingfield, in Eſſex: they were ſet about ſeven feet aſunder, in holes dug ſufficiently large, to admit the roots without turning or cramping them. Scarce a tree failed, and many of them are now (1785) in girth near the ground three feet four inches; at ſix feet high about two feet ſeven inches; and about twenty-five feet in height: the value of the ground about 12s. an acre; the ſoil a ſtiff clayey loam [o].

Lord Bathurſt's plantations, celebrated by Pope, are very extenſive. Including beech woods, bought, but not planted by him, they exceed 1000 acrees, are five five miles in extent, and make a noble figure when viewed a conſiderable way in the road to Glouceſter. The revenue is ſuppoſed to be about 20s. an acre. The fineſt trees are the Elms near the houſe. Two planted very early after Lord Bathurſt had purchaſed the place, were at five feet high, one ſeven feet eleven inches in circumference, the other ſeven feet three inches; they were from thirty to forty feet high before they branched. Larger than theſe have been cut down. The wych and Dutch Elm have thriven very badly; but the ſmall-leaved Engliſh, greatly. Oak will not do on this rocky ſoil. He planted Aſh in no great quantities; but many Firs and Beech. Mr. Young meaſured a Spruce Fir, known to be planted by Lord Bathurſt's own hands, not more than forty or fifty years ago, it was four feet ſeven inches in circumference at five feet high, and very lofty [p]. This was in 1786.

Auguſt 18, 1786, Mr. Young meaſured, in Mr. Fonnereau's park at Ipſwich, a Spaniſh Cheſnut, near the houſe, on the hill by ſome walnut trees, ſeventeen feet eleven inches at five feet from the ground. Another higher up, by a row of limes, fourteen feet, ſeven inches and a half. An Oak by the park pale near the road, eleven feet one inch and a half. A Beech by the road in the middle of the park, that has loſt one great arm, ſixteen feet nine inches and a half: at two feet high, eighteen feet and a half. The Oak, by the pond near the houſe, ſeventeen feet three inches.

At Helmingham, the Earl of Dyſart's: the largeſt Oak near the houſe, twenty feet ten inches and a half: at three feet high it is twenty-three feet ten inches. It holds nearly to the former ſize for about thirty feet, and after that branches into three vaſt arms. There cannot be leſs than ſixteen loads of timber in this venerable tree, which is decaying in its top. Near it is another, which meaſures at four feet and a half (for the trunk ſwells at five) fifteen feet five inches. A moſt beautiful, ſtraight and thriving one in the thorn walk, thirteen feet. It holds its ſize for about twenty feet as ſtraight as an arrow; in which length only it contains near five loads of timber: the whole height between thirty and forty feet.

A pollard Elm meaſures ſeventeen feet two inches and a half, the body about fifteen feet high. Nothing can be more beautiful than the head, which ſpreads a thick foliage, almoſt impenetrable to a ſun-beam, over a circle of thirty-four feet diameter.

An Aſh further, by a good Oak, nine feet ſix inches and a half, and about thirty-five feet high.

Auguſt 19. An Oak belonging to John Plampin, Eſq. at Chadacre, ten feet three inches and a half: it has therefore increaſed an inch and half ſince june 1785. The rook Aſh that ſtands near it, five feet ſix inches and a half, forty feet high, and very ſtraight. An Oak in the fore-meadow on the hill, ſeven feet eleven inches.

Two fine Oaks, at Auberries, belonging to Robert Andrews, Eſq.: one in 1785 was nine feet five inches, meaſured auguſt 4, 1786, it was nine feet five inches and a half. The other, which in 1785 was nine feet eleven inches, in 1786 was nine feet eleven inches and three quarters.

A young tall Elm, in the grove leading to the bath, was four feet eight inches and a half in 1785, and four feet nine inches and a half in 1786. A young Aſh by the bath houſe in 1785 was four feet one inch, in 1786, four feet two inches [q].

Girt at 3 feet high.

Larches at Blair Athol and Dunkeld, and at Taymouth, planted fifty years ago, full eight feet in circumference, at five feet high.

Scotch Firs planted in 1696, from two to three feet in diameter, in a century; whereas the beſt Chriſtiana deal of the ſame age is ſeldom above a foot in diameter. Theſe old Firs ſell from 1s. 6d. to 1s. 9d. a foot; and thoſe of thirty years old yield 1s. a foot.

Larches planted by Mr. Johnes of Hafod in Wales, in 1796, then eighteen inches to two feet in height; in 1802 were from ten to thirteen feet high. The medium growth there is from twenty inches to two feet in a year.

Some of my young Spruce Firs and Larches have ſhot this ſeaſon, 1805, from twenty-ſeven to thirty-one inches and near three feet.

From trunks of old trees cut down in 1777, in Adventure Bay, Captain Bligh ſaw ſhoots, in 1788, about twenty-five feet high, and 14 inches in circumference. Mr. Nelſon ſaw a tree thirty-three feet and a half in girt: and many of the foreſt trees there are full 150 feet in height.

Many of the facts regiſtered above, may aſſiſt in forming a judgment of the comparative growth of timber trees.

   Pæderota Wulfenia. *Lamarck encycl. t.* 13. *f.* 2.

DESCRIPTION, &c.

This is a ſtemleſs plant, nearly allied to the Pæderotas. Root perennial. Leaves radical, obovate, obtuſe, groſsly crenate, ſmooth. Scape round, ſomewhat hairy, much higher than the leaves. Flowers peduncled, ſupported by a lanceolate bracte, all directed the ſame way, blue. Native of Carinthia, on the higheſt Alps, in a very fat ſoil*.—Dr. Smith adds Pæderota Buonarota and Ageria to this genus.

WURMBEA. (*So named by Thunberg, in honour of Fredrik Baron van Wurmb, ſecretary to the Batavian ſociety.*)

Lin. gen. Schreb. n. 617. *Thunb. nov. gen.* 18.

Claſs. 6. 3. Hexandria Trigynia.

Nat. Order of *Coronariæ. Juncі* Juſſ.

GENERIC CHARACTER.

CAL. *Perianth* one-leafed, tubular, ſix-cornered, half-ſix-cleft: *ſegments* lanceolate, acute, erect or ſpreading.

COR. none.

STAM. *Filaments* ſix, filiform, erect. *Anthers* roundiſh.

PIST. *Germ* three-ſided, grooved, ſmooth, ſuperior. *Styles* three, three-ſided, awl-ſhaped, length of the ſtamens. *Stigmas* obtuſe.

PER. *Capſule* oblong, three-ſided, three-grooved, three-celled, three-parted from the middle.

SEEDS numerous, round.

ESSENTIAL CHARACTER.

Cal. none. *Cor.* ſix-parted, with a hexangular tube. *Filaments* inſerted into the throat.

SPECIES.

1. Wurmbea pumila.

   Spike many-flowered, length of the leaves, tube length of the border bell-ſhaped.
3. Wurmbea longiflora.
   Lin. ſpec. ed. Willd. 2. 266.
   W. capenſis δ. *Thunb. diſſ.* 1. 19. *f.* α.
   Wurmbea *Lamarck illuſtr. gen. t.* 270. *f.* 2.
   Melanthium monopetalum. *Lin. ſuppl.* 231. *Diſſ. noſtr. n.* 10.
   M. Wurmbeum. *Thunb. prodr.* 67.
   Spike many-flowered, longer than the leaves, tube twice as long as the border.

DESCRIPTIONS, &c.

1. Plant an inch high. Spike ſcarcely longer than the leaves. In ſandy grounds near the Cape of Good Hope.

2. A finger's length or more. Leaves as in all the ſpecies, three lanceolate cowled ventricoſe at the baſe, but narrower than in the following ſpecies, and the ſame

* Willdenow.

length

with the ſpike, which is beſet with numerous flowers. On ſandy hills near the Cape of Good Hope.

3. Leaves much wider than in the preceding ſpecies. Spike more flexuoſe at the baſe, with numerous flowers more diſtant. Tube of the corolla long and narrow. Native of the Cape of Good Hope, near Groene Kloof, and elſewhere.

Thunberg after having conſtituted this genus, ſunk it in the Melanthium: but the corolla being one-petalled and having a tube; theſe are ſufficient marks of diſtinction in the Liliaceous tribe. The varieties indicated by Thunberg, are really diſtinct ſpecies[1].

X.

XANTHE. (*So named from the yellow juice which it contains.*)

DESCRIPTIONS, *&c.*

1. Stalk round, with many black ſpots, riſing in good ground two feet high, and ſending out a few ſide branches. Leaves on ſlender foot-ſtalks, near four inches long, heart-ſhaped, but ſome of the largeſt cut into three acute lobes, they are irregularly indented on their edges, end in acute points, and are of a pale green on their under ſide, but of a dark green on their upper. Peduncles axillary. Flowers in looſe ſpikes, herbaceous, collected into roundiſh heads.

[Root annual, fibrous. Leaves alternate, on long petioles, ſerrate, pubeſcent, rugged. Racemes leafy, few-flowered. Males in a branched bunch, terminating the ſtem and branches; anthers ſeparate, not united as in the claſs Syngeneſia. Female flowers immediately beneath, in the boſoms of the upper leaves. Fruits elliptic, pubeſcent, muricated all over with rigid hooked briſtles [a].

The female calyx is changed into an involucre to the ſeed; it is coriaceous, oblong, within divided by a longitudinal partition, ending at top in two horns, which at firſt are ſtraight, but afterwards curved inwards and hooked, gaping in the inner ſide by a longitudinal cleft, but not ſplitting. Seeds in each cell one, ovate-oblong, attenuated at both ends, ſtriated, convex on one ſide, flat on the other, dark brown [x].

The leaves are bitter and aſtringent. A decoction of the whole plant affords a ſhowy yellow colour; but it is better if only the flowers are uſed. Horſes and goats eat it. Cows, ſheep, and ſwine refuſe it [y].

Native of Europe, of Africa about Algiers, of China and Cochinchina, in fields and hedges common. Mr. Miller ſays he received the ſeeds from India. In England it was found by Merret in a bog beyond Peckham; Ray ſays he found it once in the road from Portſmouth to London, about three miles from the former. Tho. Williſel and Mr. Newton both obſerved it about Dulwich;] where Mr. Miller ſays he once ſaw it in the road near the College, but that of late years it has not been ſeen in the few places where it was formerly remarked.

2. The ſtalks of this are much thicker, and riſe higher than thoſe of the firſt; the leaves are not hollowed at their baſe, nor are they divided ſo deeply on their ſides; they are unequally indented on their edges, and have three ſtrong longitudinal veins. The flowers are produced in ſhorter looſer ſpikes. The fruit is much larger, and armed with ſtronger ſpines.

[It is very like that of the preceding ſpecies, but almoſt twice as big, ferruginous not pale ſtraw-colour, and ſomewhat tomentoſe about the baſe of the beaks and ſpines; not ſmooth all over, as that is. Seed of a long elliptic form, ſtriated, brown [z].

The whole plant is more rugged. Leaves ovate, wedge-ſhaped at the baſe, indiſtinctly three-lobed, or five-lobed. Fruit three times as big and longer, with two diſtant hooked beaks. The male flowers have recurved chaffs twice as long as the floret. There are linear bractes to the fruits, either ſingle or in pairs.

Native of China, Japan, Ceylon and Siberia. Linneus doubts whether the American plant be the ſame with this [a]. Cultivated 1713, by Bp. Compton [b]. It is annual, as the firſt is, but flowers later, namely in auguſt.

3. Stem a foot and half high; rough with cloſely preſſed briſtles: branches very ſhort, alternate: leaves a palm or more in length; rough, tooth-ſerrated, with unequal ſerratures, ſomewhat obtuſe, three-nerved, ſubcordate, and ſubtrilobate: footſtalks the length of the leaves, and ſpreading; rough, and purpliſh. Male flowers collected into a ſeſſile head of the ſize of a large pea: Female axillary ſeſſile, remote from the males. Native of North America [c].

4. The ſtalks of this riſe near three feet high, and ſend out many branches the whole length. Leaves oblong, indented on their edges, ending in acute points, from two to three inches long, and three quarters of an inch broad, dark green on their upper ſide, but hoary on their under, on very ſhort foot-ſtalks. The flowers come out from the ſide of the branches, two or three at each place; one of them is female, and is ſucceeded by an oblong-ovate fruit, armed with ſlender ſharp erect ſpines. The ſtalks and branches are armed with long ſtiff triple thorns on every ſide.

[The three-forked ſpines, according to Linneus, are ſtipules, one of which becomes a fruit. This is ovate-cylindrical, terminated by a ſimple awl-ſhaped ſtraight cartilaginous ſmooth beak. Prickles diſtant, horizontal, briſtle-ſhaped, rigid, with little hooks at the tip. Seeds oblong, ſemicylindrical, blackiſh [d].

Native of Portugal and the South of France.] Mr. Miller ſays Portugal and Spain. It flowers in july and auguſt; and in warm ſeaſons the ſeeds ripen in autumn. [Cultivated 1713 by Bp. Compton [e].]

Mr. Miller has another ſpecies, (n. 4.) which he ſays grows naturally in China, whence he has often received the ſeeds. The plants are like thoſe of the firſt ſort, but grow larger and branch more. The flowers are produced in looſe ſpikes at the top of the ſtalks. The fruit is like that, but the ſpines are ſlender, ſingle and ſtraight. This flowers about the ſame time with the *ſpinoſum*, but unleſs the autumn proves warm, the ſeeds will not ripen in England. [It is probably a variety of the firſt ſort.

5. Stem the height of a man, perennial but ſcarcely woody, erect, roundiſh, obſcure, ſomewhat hairy: branches axillary or lateral, ſhort. Leaves alternate, even or ſlightly wrinkled, petioled, pubeſcent underneath. The floral leaves and firſt leaves of the branches lanceolate, undivided, quite entire. Common leaves oblong, pinnatifid: ſegments five, oblong, acuminate, ſubſinuate or groſly ſubſerrate. Petioles commonly ſimple, pubeſcent: on the larger leaves with membranaceous margins running down from the leaf. Male ſpike terminating. Native of Peru [f]. Cultivated in 1759, by Mr. Miller [g]: for whoſe deſcription ſee Ambroſia arboreſcens.

PROPAGATION AND CULTURE.

All theſe plants, except the laſt, are annual. The firſt will come up from the ſeeds which fall in autumn, and requires no other care but to thin the plants, and keep them clear from weeds. The ſecond ſort will do the ſame when the autumn is favourable: but it often happens with us that the ſeeds do not ripen.

The fourth ſort will alſo in ſome years perfect ſeeds on ſelf-ſown plants, but as they ſometimes fail, the ſure way is to raiſe the plants on a gentle hot-bed, and to plant them out on a warm border in a lean ſoil: for when they are planted in rich ground, they will not produce flowers till late in autumn, and the ſeeds will not ripen.

[For the culture of the fifth ſort, ſee Ambroſia arboreſcens.

DESCRIPTION, *&c.*

This is a low ſhrub, about three feet in height. The root is woody, branched, yellow without, ſaffron-coloured within, and puts forth runners. Stems from the root numerous, almoſt ſimple, erect. Branches alternate, round, marked with rings, aſh-coloured, with the inner bark yellow. Leaves alternate, unequally pinnate, two-paired, ſpreading, five or ſix inches long including the petiole, leaflets oppoſite, ſeſſile, (the end one moſtly petioled and bigger,) lanceolate, acute, gaſhed, ſmooth, bright green, of the ſame colour on both ſides, ſpreading, an inch and half long, and an inch wide. (Willdenow ſays they are ovate-wedgeform and gaſh-toothed, the end one three-lobed and gaſhed.) Petioles round, flat above, widened at the baſe and embracing. Raceme proceeding from a terminating gem, compoſed of alternate racemelets; firſt erect, but afterwards nodding, pubeſcent, bracted, blood-red, from one to ſix inches long. Racemelets compoſed of three-flowered or two-flowered peduncles. Flowers pedicelled, erect, dark or duſky purple: in the terminating one the number of ſtamens ſeems to exceed that of the germs, and the contrary in the lateral ones: the terminating flower is commonly barren, and perhaps is a male hermaphrodite[a].

Native of North America. It flowers from february to april: and was introduced about 1766 by Mr. John Buſh[b]. Bartram firſt obſerved it in Georgia. Mr. Marſhall ſays it grows naturally in Carolina, and that from the yellowneſs of its roots, it is highly probable it might be employed to good purpoſe in dyeing.]

DESCRIPTION, *&c.*

1. This riſes to the height of fifteen or ſixteen feet. Stem woody, about a foot thick, covered with a whitiſh rough bark, and armed with ſhort thick ſpines, growing to a large ſize as the trunk increaſes in bulk, ſo as to become protuberances terminating in ſpines. Leaves in pairs, or without order, compoſed of three, four or five pairs of lanceolate leaflets placed oppoſite, and terminated by an odd one; they are, of a deep green on their upper ſide, and of a yellowiſh green beneath, a little ſerrate, and on ſhort foot-ſtalks. At the end of the branches come forth the peduncles, branching out and forming a looſe panicle. Leaflets of the calyx ſmall, white. Anthers reddiſh. In the female flowers five ſtyles faſtened to the ſide of the germ. Capſule roundiſh four-cornered, containing one roundiſh, hard, ſhining ſeed. It is ſometimes called Pellitory-tree.

Mr. Miller regards this as different from the prickly yellow Wood, or yellow Hercules of Jamaica, which is one of their largeſt timber trees, with the leaves twice as big, the leaflets almoſt three inches long, and an inch and half broad, ſitting cloſe to the foot-ſtalk; and the leaves are equally pinnate. The capſules have five cells, each containing one black, ſhining, hard ſeed.

[Browne ſays it is frequent in moſt parts of Jamaica, growing to a very conſiderable ſize; riſing frequently to the height of twenty or thirty feet, and branching pretty much towards the top: that it is looked upon by many as a dye-wood, but is generally uſed in buildings, and eſteemed a good timber tree.—He deſcribes it as having a five-parted calyx, but ſo ſmall as to be ſcarcely obſervable; the corolla cut almoſt to the baſe into five ſpreading oblong-ovate ſnail-ſhaped ſegments, five ſtamens, ſtyle ſcarcely any, ſtigmas five, capſule five-lobed, divided beyond the middle, with one diſtinct cell to each lobe.

Murray remarks, that in the Gottingen garden all the flowers are hermaphrodite, heaped alternately at the ſides of the branches, on ſhort peduncles; calyx inferior, commonly five-parted, but ſometimes four or ſix-parted; corolla none; ſtamens divaricating, five, ſeldom four or ſix; ſtyle one, ſhort; ſtigmas globular-ovate, three, ſometimes two or four: the fruit did not ripen.]

β. Mr. Miller diſtinguiſhes two ſpecies, the firſt growing in South Carolina, the ſecond in Pennſylvania and Maryland. That has been deſcribed above: this he ſays has a woody ſtem, which riſes ten or twelve feet high, ſending out many branches towards the top, having a purpliſh bark, and armed with ſhort thick ſpines ſtanding by pairs. Leaves unequally pinnate, with four or five pairs of oblong-ovate leaflets, ſitting cloſe to the midrib, which is armed on the under-ſide with ſome ſmall ſpines: the leaflets are of a deep green above, and of a pale green beneath: they have a biting taſte. The bark of the tree is uſed to cure the tooth-ach, whence its name. The flowers grow in looſe panicles like the other, and are ſucceeded by fruit with five cells, each including one hard ſhining ſeed.

[Mr. Marſhall, in his American Grove, thus deſcribes it. It riſes with a pretty ſtrong ſtem to the height of ten or twelve feet, dividing into many branches covered with a purpliſh bark, and armed at

Digitized by Google

at each bud with two ſtrong ſharp ſpines. The leaves are compoſed of four or five pairs of leaflets, terminated by an odd one; they are entire, of an oblong-ovate ſhape, oppoſite and ſitting cloſe to the common foot-ſtalk, which has a few ſpines underneath. The flowers are produced along the branches upon ſhort collected foot-ſtalks: the females are each ſucceeded for the moſt part by five diſtinct oval capſules, joined by ſhort footſtalks to the common receptacle, and ſpreading above; each containing one roundiſh ſmooth ſeed. This grows naturally in Pennſylvania and Maryland.

There is ſaid to be another ſpecies, or perhaps variety, in South Carolina, differing in having the leaflets lanceolate, ſerrate, and petioled. The bark and capſules are of a hot acrid taſte, and are uſed for eaſing the tooth-ach: a tincture of them is alſo much commended for the cure of the rheumatiſm.

It was cultivated by Mr. Miller ſome years before 1740.]

PROPAGATION AND CULTURE.

Theſe plants are generally propagated by ſeeds, but as they never ripen in this country, they muſt be procured from thoſe places where they naturally grow, or the plants muſt be propagated by layers. When the ſeeds arrive in England, they ſhould be ſown in pots filled with light earth as ſoon as poſſible, for they do not grow the firſt year; and when they are kept out of the ground till ſpring, they frequently lie two years in the ground before the plants appear; therefore the pots ſhould be plunged into the ground up to their rims, in an eaſt-aſpected border, where they may remain during the ſummer; this will prevent the earth in the pots from drying too faſt, which it is very apt to do when the pots are ſet upon the ground in the ſun. The only care to be taken of the ſeeds is, to keep the pots conſtantly clean from weeds, and in very dry weather to refreſh them now and then with water. In autumn the pots ſhould be placed under a common hot-bed frame, where they may be ſcreened from froſt, or elſe plunged into the ground in a warm border, and covered with tan to keep out the froſt, and the following ſpring they ſhould be plunged into a hot-bed, which will bring up the plants. When theſe appear, they muſt be frequently, but ſparingly watered, and kept clean from weeds; and, as the ſummer advances, thoſe of the ſecond ſort ſhould be gradually inured to bear the open air, into which they ſhould be removed in june, placing them in a ſheltered ſituation, where they may remain till autumn, when they muſt be placed in a hot-bed frame to ſhelter them in winter. The ſpring following, before the plants begin to ſhoot, they ſhould be carefully taken up, and each planted into a ſeparate ſmall pot; theſe may be plunged into a gentle hot-bed, which will forward them greatly in putting out new roots. The after care muſt be to ſhelter them for a year or two in winter, until the plants have gotten ſtrength; then in the ſpring, after the danger of froſt is over, ſome of them may be turned out of the pots, and planted in the full ground in a warm ſheltered ſituation, where the ſecond ſort will thrive very well, and reſiſt the cold; but the firſt is not ſo hardy, ſo theſe may be planted againſt a ſouth wall, where they will thrive very well. Some of the plants of this ſort had been planted in the open air, in the Chelſea Garden, ſome years paſt, where they had thriven and endured the cold without any covering, but the ſevere winter in 1740 deſtroyed them all. Theſe plants may be increaſed by cutting off ſome of their ſtrong roots, preſerving their fibres to them, and theſe planted in pots filled with light earth, plunging them into a moderate hot-bed, will cauſe them to puſh out roots and become plants; but theſe will not thrive ſo well, nor grow near ſo large as thoſe which are raiſed from ſeeds.

Stem herbaceous quite ſimple, leaves lanceolate ſerrate.]

DESCRIPTIONS, *&c.*

1. Root annual. Stalk two feet high, ſlender, ſtiff and branching, covered with a white down, and channelled

Digitized by Google

nelled the whole length. Leaves lanceolate, an inch and half long, and one third of an inch broad in the middle, hoary, ſeſſile, ſpreading, alternate, diſtant. Upper part of the flowering branches naked, one-flowered. Calyx ſilvery: that and the corolla dry, and retaining their beauty a long time.

[Chaffs of the receptacle linear-acuminate, rigid, a little longer than the belly of the calyx. Seeds in the female flowers none, or if any effete, and then the germ is linear-oblong, ſtriated, ſmooth, compreſſed, bald, permanent, crowned alſo by the permanent corollet. In the androgynous flowers the ſeeds are oblong, acuminate downwards, compreſſed in ſhape of a rhomb or lens, having whitiſh villoſe hairs preſſed cloſe ſcattered over them, browniſh aſh-coloured, downy. Seed-down ſcarioſe, white, five-leaved: leaflets lanceolate or triangular, acuminate briſtle-ſhaped, ſcarcely longer than half the ſeed [k].]

It varies with white and purple, double and ſingle. flowers. In its natural ſtate the flowers are ſingle: the double flowers have been obtained by culture. Where the ſeeds are carefully ſaved ſeparate, theſe varieties are generally conſtant.

[Native of the South of Europe; flowering in july and auguſt. It was cultivated in the Oxford Botanic Garden in 1658 [k].

2. The ſtalks of this do not riſe more than a foot high, and do not branch ſo much as the preceding. The leaves are narrower, and the whole plant is very hoary. The flowers are not half ſo large; but the ſcales of the calyx are very neat and ſilvery.

[Linneus, who conſiders theſe and the next ſpecies as one; thus diſtinguiſhes the two firſt as varieties The firſt is a robuſt erect plant, with more and ſmaller ſeeds, a ſcarioſe calyx, entire chaffs, and a polypetalous ray. The ſecond is a narrower weak plant, with ſix or ſeven larger ſeeds, the calyx-ſcales membranaceous only at the edge, the chaffs jagged, and about ſix petals in the ray. The firſt, he ſays, is native chiefly of Auſtria; the ſecond of Italy, Switzerland and the South of France.]

3. This riſes about the ſame height as the firſt ſort. The leaves are narrower, and placed cloſer on the ſtalks to the top. The flowers are much leſs, of a paler purple colour, and have a cylindrical calyx. The ſeeds are very large, and ſeldom more than three or four in a head.

Flowers as big as thoſe of the firſt ſpecies or bigger. Seed-down many-leaved, chaffy. Chaffs ſcarioſe ſhining white ovate long-awned longer than the calyx [l].

Found in Armenia by Tournefort.

Theſe are both annual as well as the firſt; and are the only ſpecies that agree perfectly with the character of Xeranthemum, as given by Linnæus. Gærtner therefore has divided the genus into three, and refers all the ſpecies of Xeranthemum, Gnaphalium, and Filago, which have not florets diſtinct in ſex, the ſeed-down neither feathered nor pencilled, the receptacle neither villoſe nor chaffy, to the genus Elichryſum. Linneus's Xeranthema and Gnaphalia to which he attributes a feathered ſeed-down, having a naked ſmooth receptacle, androgynous and female florets mixed, and the calyx as in Xeranthemum, Gærtner names Argyrocome. Dillenius had called it Xeranthemoides.

Willdenow ranges all the following ſpecies under Elichryſum. They have a naked receptacle, and a hairy or feathered ſeed-down: whereas the true Xeranthema have a chaffy receptacle, and a ſetaceous-chaffy ſeed-down.

4. The whole plant is covered with a very thick nap, whence its trivial name. It is very diſtinct by having the floral leaves furniſhed with a lanceolate membrane at the end.

β. Differs only in having the calyx-ſcales browniſh at the tip.

Native of the Cape of Good Hope. Introduced in 1774 by Mr. Francis Maſſon [l].

5. This differs from the preceding in having lanceolate keeled leaves, the floral ones not appendicled, and ſpirally imbricate, the flowers large white and ſplendid, with the calyx-ſcales red at the tip. Native of the Cape of Good Hope [m].]

6. This riſes with a ſhrubby ſtalk three or four feet high, dividing into four or five branches, the lower parts of which have thick-pointed leaves, about two inches long and an inch broad, hoary on their under ſide, and ranged without order. The upper part of the branches are naked, and terminated by one large yellow flower.

[The ſeed-down is feathered [n]. Native of the Cape of Good Hope.—Said in the Kew catalogue to be introduced by Mr. Maſſon in 1787.

7. Stem the thickneſs of a finger, woolly, divided at the top into flowering branches. Leaves approximating, the length and breadth of a finger, erect and ſubimbricate, white and ſoft like ſome of the Gnaphaliums. Flowers like thoſe of a Xeranthemum and ſeſſile, with the herb of Gnaphalium. Calyxes the ſize of a walnut, with numerous deep yellow and very ſhining rays. Florets numerous and very ſmall. Native of the Cape of Good Hope [o]. Introduced by Maſſon in 1774.

8. Branches ſpreading, rigid. Leaves imbricate all round with leaflets, which one ſcarce knows whether to call leaves or branchlets. The flowers have a very ſhining blood-red ray. Native of the Cape of Good Hope [p].

9. Calyxes ſhining, white, rufous on the outſide in the middle. Seed-down red [q].

Native of the Cape of Good Hope.

10. Calyxes ſhining, purple: the loweſt ſomewhat teſtaceous. Seed-down white [r]. Native of the Cape of Good Hope.

11. Branches ſimple, two inches long, filiform. Leaves very ſmall, ſmooth. Peduncles tomentoſe. Flower the ſize of Bellium minutum. Native of New Zealand [s].

12. Leaves convolute, ſilvery. Native of the Cape of Good Hope [t].

13. Stem ſhrubby with pubeſcent branches. Leaves alternate, ſtiffiſh, acute, channelled, with a cloſe-preſſed pubeſcence underneath. Calyxes ſolitary, blood-red, ſmooth, acuminate, white above. Diſk yellow. Native of the Cape of Good Hope [u].]

14. Stalks ſlender, woody, trailing to three or four feet in length. Leaves ſmall, ſilvery, placed without order, ſeſſile, reflexed. Flowers axillary, ſolitary, or two or three together, with a white ray.

[Stem a foot and half long, with many twiſted diffuſed branches. Leaves oblong, ſinuate-gaſhed, tomentoſe, hoary. Flowers yellow. Receptacle almoſt naked. Seed-down hairy [x].—Dillenius ſays that it is feathered, as it certainly is.

Receptacle flat, wide, hollow-dotted ſmooth. Seeds oblong, roundiſh, ſmooth, pale: down ſnow-white, three times as long as the ſeed, with numerous rays, briſtle-ſhaped at the baſe, toothletted, pencil-feathered at the tip [y].

Native of the Cape of Good Hope, and Cochinchina. Cultivated in 1732, by James Sherard, M.D. of Eltham [z].

15. The ſtem ſeems to be herbaceous and weak, and therefore it is procumbent and rooting. The branchlets up to the flower are clothed with ſmall ſilky ſilvery leaves. The flowers are ſmall and red. The ſeed-down is feathered. Native of the Cape of Good Hope [a].

16. Stem decumbent rooting: Leaves ſilvery. Native of the Cape of Good Hope [b].

17. Root woody perennial. Stems branched diffuſed procumbent herbaceous, with the branches a finger's length. Leaves extremely ſmall, a line in length obtuſe hoary imbricate in four rows. Flowers at the ends of the branches, ſolitary, ſeſſile, the ſame ſize as in the caneſcens. Calyx ſnow-white, pubeſcent on the outſide [c].

Found

Found by Billardiere on the higheſt parts of Mount Libanus; alſo in Corſica.

18. This is diſtinguiſhed by its ſpiny head, which is compact and purple. Native of the Cape of Good Hope.]

19. Stem ſhrubby branching, riſing three or four feet high. Branches ſlender, like thoſe of Spaniſh Broom, but hoary. Leaves very ſmall, reſembling ſcales, ſeſſile, narrow, hoary, ending in acute points. Each branch is terminated by one large ſilvery flower.

[The calyx in ſome is white, in others purple[d]. Native of the Cape of Good Hope.

20. Stem woolly-tomentoſe, white, branched. Leaves ſubcylindrical but flatted a little above, beneath convex and ſmooth, the lower ones an inch or an inch and half long, in bundles, the upper ones and thoſe on the branches twice or thrice ſhorter, preſſed cloſe, alternate. Flowers the ſize of the preceding, on ſcaly peduncles. Calyx-ſcales lanceolate, acute, white or yellow. Native of the Cape of Good Hope[e].

21. This differs chiefly from the ſeſamoides in having the calyx yellow. David van Royen informs us that the anthers are tailed. Native of the Cape of Good Hope[f].

22. 23. Found at the Cape of Good Hope by Thunberg.

24. Stem woody, tender, panicle-branched. The whole plant white-tomentoſe. Peduncles long, terminating. Native of the Cape of Good Hope. Dav. van Royen[g].

25. A foot high or more, with a ſtout thick ſtem, abundance of leaves from top to bottom in no regular order, divided into a few branches. Leaves narrow, ſeſſile, very hoary, more than an inch in length, and one third of an inch in breadth. The ſtem and branches are terminated each by one large white flower; each ſcale of the calyx having a ferruginous ſpot at the top[h]. Native of the Cape of Good Hope.

26. Native of the Cape of Good Hope.

27. Stem round, erect, ſmooth, a foot and half high. Leaves ſmoothiſh, alternate, petioled. Flowers yellow, in a few-flowered terminating panicle. Inner calyx-ſcales reflexed at the end, longer than the florets. All the ſeeds crowned with a many-briſtled down. Receptacle with deciduous chaffs. Native of China about Canton[i].]

PROPAGATION AND CULTURE.

1, 2, 3. Sow the ſeeds in the ſpring or autumn on a border of light earth; but the latter ſeaſon is preferable, for thoſe plants which come up in autumn will flower ſooner, the flowers will be more double and much larger than thoſe which are ſown in the ſpring, and from theſe good ſeeds may be always obtained, whereas the ſpring plants many times fail in cold years, and in hot dry ſeaſons the plants do not grow to any ſize.

When the young plants are about two inches high, prick them out into another border under a warm wall, pale or hedge, at four or five inches diſtance; or into the borders of the flower garden. They will thus endure the cold of our ordinary winters extremely well, and in the ſpring will require no farther care but to keep them clear from the weeds. In june they will begin to flower, and at the beginning of july the flowers will be fit to gather for drying; but a few of the beſt and moſt double flowers ſhould be ſuffered to remain for ſeed, which muſt be ſown annually.

4, &c. The other ſorts, being moſtly ſhrubby, and not ripening their ſeeds in England, are propagated by cuttings, planted on a bed of light earth, during any of the ſummer months, and ſhaded from the ſun. When they have gotten ſufficient ſtrength, take them carefully up, and plant them in ſeparate pots filled with light earth, and place them in a ſhady ſituation till they have taken freſh root; and then remove them to a ſheltered place, where they may have more ſun, and there they may remain till autumn, when they muſt be removed into ſhelter, for they are too tender to live abroad through the winter in England, though they do not require any artificial warmth. They may be kept in a common hot-bed frame all winter, expoſing them always to the open air in mild weather, but covering them in froſt: and theſe plants will be ſtronger and flower better than thoſe which are placed in the greenhouſe, where they are apt to draw up weak, and not to flower; nor are the plants ſo handſome as thoſe which are more expoſed to the open air. In ſummer they ſhould be placed abroad in a ſheltered ſituation with other hardy exotic plants, and in dry weather they will require to be often watered, but in winter ſparingly. As theſe plants are not of long duration here, and after four or five years become unſightly, young plants ſhould be raiſed to ſucceed them.

Leaves ovate, peduncles one-flowered.]

DESCRIPTIONS, &c.

1. This riſes with a woody ſtem twenty feet high, ſending out ſeveral branches on every ſide, armed with thorns. Leaves lanceolate, ſtanding round the branches without order. Flowers terminating. Corolla compoſed of one bell-ſhaped petal, cut almoſt to the bottom into three ſegments which are rolled back and are hairy; they are of a yellow colour within, and are ſucceeded by an oblong, oval, fleſhy fruit, ſhaped like a Plum, and including a hard nut of the ſame form.

[It is a tree or ſhrub, with the trunk and branches ſmooth; the branchlets ſpiny, round, ſtriated. Leaves in alternate cluſters, two or three together, ovate (or ovate-oblong,) ſeldom emarginate, entire, nerved, ſmooth on both ſides. Petioles roundiſh, flat above, ſmooth. Spines lateral, erect at the baſe of the petioles, longer than the petioles, thickiſh, awl-ſhaped. Peduncles axillary or from the tubercle of the petioles, ſhorter than them, bent down, round, from three to five-flowered; pedicels one-flowered.

Calyx

Digitized by Google

Calyx four-cornered, four-toothed, very ſmall, ſpreading. Petals four, lanceolate, converging at the baſe, reflexed, hairy within, pale, ſmooth on the outſide. Filaments eight, ſhorter than the petals. Anthers concealed within the beard of the petals. Drupe the ſize of a ſmall apple, roundiſh, yellow when ripe: containing a ſpherical nut with a white kernel in it[k].

According to Jacquin, this tree is upright, and about fifteen feet high. Leaves emarginate, two inches long, three or four together from alternate tubercles, armed at the ſide with a ſtrong ſpine, four lines in length: but theſe are ſometimes wanting on a whole branch. Peduncles ſhorter than the leaves, two three or four from the ſame tubercle, racemed, and five-flowered or thereabouts. Flowers whitiſh, having a very ſweet odour, ſomewhat like that of frankincenſe. Fruit yellow, ſhining, the ſize of a pigeon's egg, with a very thin rind, and little ſweet ſubacid pulp, which is eaten by the ſavages and children. Nut ſmoothiſh, dirty white, incloſing a kernel ſhaped ſomewhat like a nutmeg, white and of a pleaſant taſte. Plumier figured the corollas as three-petalled[l], and Mr. Miller adopted the error.

Native of the Weſt Indies; about Carthagena, St. Domingo, Hiſpaniola, &c. flowering in july according to Swartz; in ſeptember and october as ſeen by Jacquin.

Cultivated in 1759, by Mr. Miller[m].

2. This has no thorns. Native of New Caledonia[n].

3. This is a very buſhy tree, divided much towards the top, not above eight or nine feet in height. Trunk about four inches and a half in circumference. Leaves not above an inch in length, and diſpoſed very thick upon the ſmaller branches. Native of Jamaica[o].]

PROPAGATION AND CULTURE.

Theſe trees are propagated by ſeeds, which muſt be procured from the countries where they grow naturally; they ſhould be ſown in pots filled with light earth, and plunged into a good hot-bed of tanners bark. If the ſeeds are freſh, the plants will appear in ſix weeks or two months. When theſe are about three inches high, they muſt be each carefully tranſplanted into a ſeparate ſmall pot filled with light earth, and plunged into a good hot-bed of tanners bark, where they muſt be ſhaded from the ſun till they have taken new root; then they muſt be treated in the ſame manner as other tender plants from the warm countries. During the firſt ſummer they may be kept in the tan-bed under frames, where they will thrive better than in the ſtove; but in autumn, when the nights grow cool, they ſhould be removed into the ſtove, and plunged into the tan-bed; and in this they ſhould always be kept, obſerving to ſhift them into larger pots when they require it; and in ſummer, when the ſeaſon is warm, they ſhould have a large ſhare of free air admitted to them. With this management the plants will thrive well, but they cannot be expected to flower very ſoon in this country.

DESCRIPTION, &c.

This is a tree of various dimenſions, commonly of a large ſize, but ſometimes only a ſhrub. Trunk erect, covered with a cloven hard duſky-cheſtnut-coloured bark, and of a middling thickneſs. Frond oblong, ſometimes ſubglobular opaque. Larger boughs ſcattered; ſmaller commonly oppoſite, covered with a duſky-aſh-coloured bark, numerous. Leaves oppoſite, ſpreading, oblong-club-ſhaped, rounded, or ſometimes oblong, acute, quite entire, ſcarcely convex on the upper ſurface, ſmooth, ſhining, dark green; on the lower ſurface veined, with the midrib more prominent ſtiffiſh, a little bigger than apple leaves. Petioles ſpreading, a little curved, roundiſh, ſomewhat wrinkled, cheſtnut-coloured, ſhort. Racemes ſcattered on the branches, ſometimes axillary, ſomewhat erect, ovate-oblong, ſmall, ſhorter than the leaves, partial ones oppoſite, terminating ones commonly

Digitized by Google

trichotomous and ſpreading very much. Peduncles round, ſmooth, tough, coloured, red, naked. Peduncles ſhorter than the flower.

Native of the Eaſt Indies; in woods that grow in the ouze on the ſea coaſt, among the Rhizophoras[p].

XYLOMELUM. (*From* ξυλον *wood, and* μηλον *an apple.*)

Smith in Linn. Tranſ. 4. 214.

Claſſ. 4. 1. Tetrandria Monogynia, prope Banksiam.

Nat. Order of *Proteæ* Juſſ.

ESSENTIAL CHARACTER.

Ament with a ſimple ſcale. *Pet.* four, ſtaminiferous. *Stigma* club-ſhaped, obtuſe.

DESCRIPTION, *&c.*

Habit altogether of *Brabeium*; but it has a wooden capſule, opening at the top on one ſide, and containing two winged ſeeds, not an almond-like drupe with one ſeed. Many of the flowers with a ſmaller ſtigma are abortive.

Native of Auſtralaſia.

This is one of twenty new genera, from the South Seas, the characters of which are given by Dr. Smith.

XYLON. See *Bombax* and *Goſſypium.*

   Pharnaceum ſuffruticoſum. *Pallas it.* 3. *app.* 29. *n.* 70. *t. E. f.* 2.
   Leaves elliptic, flowers axillary.

DESCRIPTIONS, *&c.*

1. Stem ſuffruticoſe, even. Branches quadrangular, alternate, ſtiff; the angles acute. Leaves linear, alternate (often two together,) ſtiff, even, ſomewhat keeled, longer than the interſtices, alternately and very remotely ſerrate, with the ſerratures floriferous[q].

Linneus depended upon Rumphius for this ſpecies, and never ſaw the flowers himſelf. Rumphius's deſcription by no means agrees with the character of this genus[r].

2. Stem ſhrubby, one or two feet high. Branches irregular, roundiſh-compreſſed. Leaves diſtich, alternate, ſcarcely petioled, crenate towards the end, ſmooth on both ſides, ſtiffiſh. Flowers cluſtered, peduncled, polygamous, hermaphrodite and female mixed. Females always terminating, longer pedicelled. Calyx in both ſorts ſix-parted, coloured, permanent. In the hermaphrodites ſix very ſhort filaments, with roundiſh depreſſed anthers. Germ ovate. Style erect, longer than the ſtamens, three-parted, Stigmas reflexed, entire, obtuſe, yellow. Capſule three-celled: cells two-valved, two-ſeeded. Seeds ovate, flat on one ſide. In the females, ſtigmas trifid and rudiments of ſtamens faſtened to the germ. Germ, ſtyle and capſule as in the others.

Native of the Weſt Indies, on maritime calcareous rocks. Linneus made out the character of the genus from this ſpecies as given by Browne[s].

It was introduced here in 1783, by Matthew Wallen, Eſq. and flowers from auguſt to october[t].

3. A moſt elegant, evergreen plant, with a woody ſtem, about three feet high, very ſimple, and upright, and about a finger's thickneſs: bark aſh-coloured, marked with tubercles from the fallen leaves; leaves alternately ſpreading on the top of the plant; ſtrong, ſmooth, footſtalked, and pinnated with five or ſix leaflets, without an odd one; all lanceolate, ſerrulated, and coriaceous; the younger ones often purpliſh: from the notchings of the leaves proceed ſlender footſtalks of half an inch in length, each bearing a ſingle flower, which is ſmall and of a pale ſulphur-colour[u].

4. This is a ſhrub of five or ſix feet height, with many upright ſtems growing from the root: leaves generally four or five inches long; with the edges widely notched; the notches being at about three quarters of an inch diſtance from each other: from each notch grows a ſmall, monopetalous, red flower, ſucceeded by a ſmall red berry. Native of the Weſt-Indian Iſlands *.]

5. This tree grows fifteen or ſixteen feet high. The leaves come out without any order, they are five or ſix inches long, ſmooth and thick; the flowers are produced upon the edges, but eſpecially towards the upper part, where they are placed very cloſely; theſe,

[p] Koenig in Willd. ſpec.

Digitized by Google

together with the ſhining green colour of the leaves themſelves, make a very beautiful appearance: the leaves continue green all the year. It grows naturally upon the rocks near the ſea in the iſlands of the Weſt Indies.

[In the Kew catalogue it is ſaid to be a native of the Bahama iſlands, and to have been cultivated by Mr. Miller in 1739.] Mr. Miller himſelf ſays that there was formerly a plant of it at Hampton Court; and that he alſo ſaw one in the Amſterdam garden.

[6. Native of Jamaica.

7. Leaves elliptic quite entire petioled ſcattered. Flowers five or ſix peduncled anxillary. Native of Siberia, among the rocks of the mountains Charabon and Tſchir[x].

Introduced in 1783 by Mr. John Bell[y].

PROPAGATION AND CULTURE.

All theſe, except the laſt, being natives of the Eaſt and Weſt Indies, are tender and muſt be kept in the bark ſtove.]

Mr. Miller ſays of the fifth ſort, that it muſt be placed in a moderate ſtove in winter, and that in ſummer it may be placed in the open air, in a warm ſheltered ſituation. The roots ſtrike ſo deep into the crevices of the rocks, as to render it almoſt impoſſible to tranſplant the plants; and the ſeeds will not grow, unleſs they are ſown ſoon after they are ripe.

[XYLOPIA.

Xylopicron. *Pluk. phyt. t.* 238. *f.* 4.

Leaves oblong-ovate ſmooth, peduncles one-flowered ſubgeminate, fruits ſmooth.

DESCRIPTIONS, *&c.*

1. This tree grows to the height of fifteen or ſixteen feet. Native of Jamaica. Browne found it at the foot of the mountains in Sixteen-Mile-walk[z].

[x] Willdenhow. [y] Hort. kew. [z] Browne.

2. Very like the preceding, but the leaves are narrower, whitiſh and ſilky villoſe underneath, not ſtrigoſe, ſmooth at the end not with a bundle of hairs; the fruit alſo is ſmooth; the peduncles are ſometimes one-flowered, ſometimes many-flowered. Native of Guiana and Braſil[a].

Capſules placed on the receptacle of the flower in a ſubglobular umbel, pedicelled, ovate, ſimple or twin, wrinkled, coriaceous, aromatic, two-celled, two-valved: partition membranaceous, thin, contrary to the valves. Seed one in each cell, oblong-elliptic, narrowing below into an umbilical dagger-point, plano-convex, black, ſhining. Aril incomplete, ſpongy-membranaceous, white, full of a very fragrant acrid oil, faſtened cloſely to the umbilical point, often inveſting the lower half of the ſeed[b].

3. This tree grows to a conſiderable ſize, and will ſometimes raiſe its branches to the height of fifty or ſixty feet. The wood, bark and berries have an agreeable bitter taſte, not unlike that of the orange ſeed. The wild pigeons feed much upon the latter, and owe that delicate bitteriſh flavour, ſo peculiar to them in the ſeaſon, wholly to this part of their food. Freſh gathered from the tree they are agreeable to the palate and grateful to the ſtomach. The bark is alſo richly impregnated with this juice as well as the wood; and both yield a very agreeable bitter in the mouth while freſh: but that delicacy diminiſhes greatly after they are dried. The wood is eaſily wrought, and eſteemed a good timber-wood, where it is not much expoſed to the weather[c].

The bitter quality of this tree is communicated with great facility. A handful of the ſhavings immerſed in water, and inſtantly taken out again, will render it of a very bitter taſte. Sugar ſent over in hogſheads made of this wood was ſo bitter that no perſon would purchaſe it. Bedſteads and preſſes made of it are proof againſt cockroaches and other inſects. Carpenters who work the wood perceive a bitter taſte in their mouths and throats. A decoction of it is ſaid to be of ſervice in cholics, and to create appetite[d]. Native of Barbadoes and Jamaica. Browne ſays that he met with it in the mountains at the back of Bull-bay; and that it ſeeds at Mr. Anderſon's mountains, near the Mine.

The common name of Bitter-wood, was tranſlated into the Greek Xylopieron or Xylopicrum, for a generic appellation, by Plukenet and Browne. Linneus ſhortened it into Xylopia, a name of no meaning.

4. Xyris capenſis.
Willd. ſpec. 1. 255. *Thunb. prodr.* 12.
Leaves linear very ſhort, head ovate acute, ſcales obtuſe.

DESCRIPTIONS, &c.

1. Scapes ſeveral, a foot high. Leaves ſometimes almoſt the length of the ſcape or a little ſhorter. Anthers linear, emarginate, with a pencil at the baſe on each ſide [e]. Vahl remarks, that he never obſerved the leaves to be ſo wide as they are repreſented in Rheede's figure.

Capſule obovate, three-cornered, opening at the corners, but cohering at top and bottom, and not ſeparating into valves. Seeds ovate-globular, ſtriated longitudinally, ſlightly pointed at both ends and theſe dark brown, in other parts rufeſcent or elſe pale with the ſtreaks only rufeſcent [f].

[e] Vahl. [f] Gærtner.

Vahl deſcribes a plant ſent from the Eaſt Indies by Koenig, which differs from this in having narrower ſhorter leaves, a ſmooth ancipital ſcape, and three-toothed anthers. It agrees with the third ſpecies in leaves and ſcape, but differs in height. He ſuſpects that the petals are not diſtinct, but cohere at bottom, not having been able to ſeparate them in his ſpecimens without tearing.

2. Native of Malabar.

3. Leaves linear, ſtiffiſh, ſhorter by half than the ſcape. Scape not ſtriated, as in the firſt ſpecies, compreſſed above. Scales of the head oblong, concave, with a thinner membranaceous margin, emarginate at the tip with a ſomewhat callous browniſh point in the middle, but never attenuated as in Aublet's figure, which is not a good one [g]. Native of South America.

4. Native of the Cape of Good Hope, where it was found by Thunberg.

DESCRIPTIONS, *&c.*

1. This ſeldom riſes with a ſtem above two feet and a half or three feet high, which has leaves almoſt to the ground. Theſe are broad, ſtiff, and have the appearance of thoſe of the Aloe, but are narrower; they are of a dark green colour, and end in a ſharp black ſpine. It frequently produces its panicles of flowers from the centre of the leaves. The flower-ſtalk is three feet high, branching out on every ſide to a conſiderable diſtance, but the flowers are placed very ſparedly on the ſtalk, which renders it leſs beautiful than the other ſorts. The flowers are white within, but each petal is marked with a purple ſtripe on the outſide: they are bell-ſhaped and hang downward. They appear in auguſt and ſeptember, but are not ſucceeded by ſeeds in England.

Native of Virginia and other parts of North America.

[Firſt cultivated in Europe by John Gerarde, who had it from the Weſt Indies, "by a ſervant of a "learned and ſkilful Apothecare of Exceſter, named "Maſter Thomas Edwards[h]."

Parkinſon adds, that Gerarde kept it to his death, but that it periſhed with him who got it from his widow, intending to ſend it to his country houſe. Gerarde ſent it to Robin at Paris, and Veſpaſian the ſon of old Robin ſent it to Maſter John de Franqueville, which plant was flouriſhing in Parkinſon's garden, when he publiſhed his Paradiſus in 1629[i].

Johnſon, the editor of Gerarde's herbal, ſays that he once ſaw it in flower in the garden of Mr. Wilmot at Bow, but never ſince, though it hath been kept for ſundry years in many other gardens as with Mr. Parkinſon and Mr. Tuggy.]

2. This riſes with a thick tough fleſhy ſtalk, to the height of ten or twelve feet, having a head or tuft of the leaves at the top; theſe are narrower and ſtiffer than thoſe of the former ſort, and are of a lighter green colour; their edges are ſlightly ſerrate, and their points end in ſharp thorns. The flower-ſtalk riſes in the centre of the leaves, and is from two to three feet long, branching out into a pyramidal form. The flowers grow cloſe on the branches, and form a regular ſpike; they are of a bright purple colour on the outſide, and white within, making a fine appearance. They appear at the ſame time with thoſe of the former, but not ſo often; and whenever they appear the head decays, but one or two young heads come out from the ſide of the ſtalk below the old one.

[Native of South America. Cultivated 1696, in the Royal Garden at Hampton Court[k].]

3. Stalks three or four feet high. Leaves narrow, dark green, hanging down, ſerrate, and ending in acute ſpines.

[The plant which flowered in auguſt 1729 at Hamburgh in the garden of Jo. Henr. de Sprekelſen, at twenty years of age, was eight feet high, and the flower-ſtem two feet and a half. The flowers pendulous, milk-white, with a ſtrong unpleaſant ſmell, about 150 in a thyrſe. Seed veſſel three-celled. Seeds horny, wrinkled, blackiſh when ripe.

The plants cultivated in the Eltham garden in 1732 were about three feet high, and had longer, narrower, and more tender leaves than the ſecond ſpecies, bending downwards from about the middle, ſhining, darker green, leſs concave, terminating in a longer ſlenderer ſpine, about an inch wide, and two feet or more in length[l].

Gærtner deſcribes the fruit as a fleſhy oblong berry, contracted at the top, with a narrow aperture between the ſeſſile ſtigmas, obſcurely ſix-cornered, and ſix-celled; cuticle very thin, not ſeparating: pulp firm of a dark duſky blood-red colour: three of the partitions thicker and three thinner; all longitudinal: between theſe are tranſverſe, membranaceous, very thin, white diaphragms, forming partial cells for each of the ſeeds. Receptacle none, except the central angle of the cells, to which the ſeeds are faſtened horizontally in a ſingle longitudinal row. Seeds numerous, ſpherically triangular, flattiſh on both ſides, dark but not ſhining.] Native of South Carolina: whence Mr. Miller ſays that he received the ſeeds by the title of Oil-ſeed.

4. The ſtalk and leaves are like thoſe of the firſt ſort, but the leaves are obtuſe, and have no ſpines at their ends. The flower-ſtalk riſes five or ſix feet high, and is generally covered with flowers moſt of its length. The flowers are larger and whiter than thoſe of the other ſpecies, and ſit cloſe to the ſtalk. From the ſide of the leaves come out long threads which hang down.

[Moriſon obſerved three-ſided, three-celled capſules, in the garden of George Crook at Waterſtock, ſix miles from Oxford, in 1675: and adds that William Walker had poſſeſſed abundance of the plants for many years, in his ſuburban garden in the village of St. James, but that he never ſaw it flowering with him.]

Native of Virginia.

PROPAGATION AND CULTURE.

All theſe plants are either propagated by ſeed, when obtained from abroad, or elſe from offsets or heads taken from the old plants, after the manner of Aloes.

When they are raiſed from ſeeds, they ſhould be ſown in pots filled with light freſh earth, and plunged into a moderate hot-bed, where the plants will come up in five or ſix weeks after; and when they are two or three inches high, they ſhould be tranſplanted each into a ſeparate ſmall pot filled with light freſh earth, and plunged into a hot-bed, where the plants ſhould have air and water in proportion to the warmth of the ſeaſon, and the bed wherein they are placed.

In july they ſhould be inured by degrees to bear the open air, into which they muſt be removed, to harden them before winter, placing them in a well ſheltered ſituation, where they may remain until the beginning of oƈtober, when they muſt be removed into the green-houſe, where they may be ranged amongſt the hardier ſort of Aloes, and ſhould be treated in the ſame manner as hath been already directed for them; to which the reader is deſired to turn, for further inſtructions.

When theſe plants have acquired ſtrength, thoſe of the common ſort, and alſo the threaded, may be afterwards turned out into a warm border, where they will endure the cold of our ordinary winters very well, but the other ſorts muſt be kept in pots, that they may be ſheltered in winter; and if they are treated in the ſame way as the large American Aloe, they will do very well.

The offsets taken from the old plants ſhould be laid in a dry place, for a week or ten days before they are planted, that their wounds may heal, otherwiſe they will be ſubjeƈt to rot with moiſture.

As the ſecond and third ſorts do not put out offsets ſo plentifully as the firſt and fourth, ſo in order to propagate them, the heads of the plants may be cut off in june; and after the wounded part is dry, the heads

[h] Gerarde's herbal, p. 1359. [i] Park. par. p. 434. [k] Hort. kew. [l] Dill. elth.

Digitized by Google

may be planted, which will ſoon take root, provided the pots are plunged into a moderate hot-bed; and this cutting off the heads will occaſion the ſtems to put out ſuckers, which they ſeldom do without until they flower; ſo that by this method, the plants may be obtained in plenty.

DESCRIPTIONS, &c.

1. Stem thick, ſeldom riſing more than two feet high. The leaves come out round the upper part of the ſtem upon footſtalks eighteen inches long; they are pinnate, the leaflets about five inches in length, and an inch and half in breadth in the middle, drawing to a point at both ends; they are ſtiff, ſmooth, and entire except a few ſmall indentures at their points, are placed alternately, and are of a pale green colour; there are fourteen or fifteen of theſe leaflets ranged along the midrib. The fruit riſes up from the ſide of the ſtem upon a ſhort thick footſtalk, ſtanding upright, and ſhaped like a club, having many red ſeeds about the ſize of large peaſe, placed in ſeparate cells round the central footſtalk, to which they adhere. All the plants which have flowered in England had male flowers only.

It was diſcovered by Dr. Houſtoun in the ſands near Old Vera Cruz in America. The firſt time he ſaw it growing the plants were in full leaf, but on his return three months after, the fruit was ripe, and all the leaves were fallen off. He obſerved the ſame in the following ſeaſon.

[It appears from Plukenet, that it was cultivated in 1691, in the Royal Garden at Hampton Court[m].

2. The ſpadix is divided into florets after the manner of the fruit of the Cypreſs[n].

Native of Eaſt Florida. Introduced in 1768 by John Ellis, Eſq.[o]

3. Native of the Weſt Indies. Introduced in 1777 by Meſſrs. Kennedy and Lee.

4. Native of the Cape of Good Hope. Introduced in 1775, by Mr. Francis Maſſon[p].

5. Stem ſwelled out like a bulb above ground, tomentoſe, imbricate. Leaves pinnate, radical or on the bulb, very like thoſe of Cycas, but not in a ring, nor with the lower pinnas ſpineſcent. The male flowers as in Cycas circinalis, but the females are like the males, and under each ſcale there are two berries, as in the ſecond ſpecies[q].

The fruit is ovate-oblong, about a foot in length, peduncled. Scales peltate, on long petioles, the petiole widening outwards, three-ſided: peltæ rhomboidal, acuminate both ways, ſuberous-coriaceous, on the outſide rugged, wrinkled, brown, within next the petiole marked on both ſides with a round pale area, and augmented near the end with a lamella turned inwards. The two berries under each pelta ovate very obſcurely three-cornered, fleſhy, ſmooth, one-celled: cuticle thin, in the old fruit pale ſtraw-coloured: pulp ſoft, ſungous, moderately thick. Seed large, ovate-globular, inverted, having a knob at the end, pale[r].

Native of the Cape of Good Hope. Introduced by Mr. Francis Maſſon in 1775[s].

Potamogit. affinis graminifolia aquatica. *Raii. hiſt.* 190.

DESCRIPTION, &c.

1. Root annual, fibrous, very ſlender. It has the habit of a Potamogeiton, ſlender and much branched, the ſtem leafy and ſmooth. Leaves ſomewhat whorled, growing two, three, or four out of the ſame ſheathing ſtipule, linear, quite entire, acute, graſs-like. Bracte axillary, tubular, membranaceous. Flowers two together within each bracte, one male, the other female. Stamen at the baſe of the pedicel of the female flower, capillary, very long: anther yellow, four-celled. Female flower pedicelled, with a bell-ſhaped calyx, unequally toothed at the mouth. Germs four or five, pedicelled, oblong, compreſſed, for the moſt part toothed or corrugated on the outſide. Styles ſhort. Stigmas large, ovate, peltate, quite entire or ſcarcely repand at the edge, by no means toothed. Seeds of the ſame form with the germs: ſomewhat compreſſed, with a dentated ridge on each ſide, and an awl-ſhaped termination, giving them the appearance of a bird's claw[a]. Gærtner ſays that the capſules are from four to eight, ſhaped as deſcribed in the generic character; with one ſeed in each, the ſhape and ſize of the cavity of the capſule, and pale-coloured.

Native of Europe and Virginia; flowering in june and july. Ditches and ſtagnant waters, near Pancras church; Bungay in Suffolk, Cherry-Hinton, &c. Cambridgeſhire; between Headington and the Wick in Oxfordſhire, &c.

Dr. Smith thinks that the plant figured by Micheli, *t.* 34. *f.* 2. may be a different ſpecies, not found, as far as he knows, in England.

In Withering this is referred to as our common ſort; and a deſcription by Dr. Stokes is referred to Micheli's *f.* 1.—Dr. Stokes obſerves, that the uncommon breadth of the ſummits (ſtigmas) is the moſt remarkable peculiarity of this plant; and whether they float upon the ſurface of the water, or are ſunk beneath it, they are equally calculated to receive the pollen, from the anthers which ſtand above them.

ZANONIA. (*So named by Linneus, in memory of Giacomo Zanoni, prefect of the botanic garden at Bologna. Author of* Iſtoria Plantarum. Bol. 1615. fol. *Edited in latin by Monti*, 1742. *He died in* 1682, *aged* 67.)

DESCRIPTION, *&c.*

The firſt of theſe grows naturally in the iſlands of the Weſt Indies; and has a very large ſtrong ſtalk, riſing the height of about ten or twelve feet. The leaves are long, broad, hang downward, and have a broad white midrib. The male flowers come out in branching ſpikes at the upper part of the ſtalks; theſe are eight or ten inches long. The female flowers come out from the bottom of the leaves on the ſide of the ſtalk; they are diſpoſed in a cloſe long thick ſpike, and are covered cloſely with thin ſpathes or ſheaths; out of the end of theſe covers hangs a ſmall long bunch of threads. When the ſeeds are ripe, the ſpikes or ears are nine or ten inches long, and ſometimes a foot; but theſe rarely ripen in England.

Mr. Miller ſays he has not ſeen any variety of colours in this, but that it is very probable there are the ſame varieties in the grain as in the others. This being leſs common in Europe, we are not ſo well acquainted with it.

The ſecond is cultivated in Italy, Spain and Portugal. The ſtalks are more ſlender, and ſeldom more than ſix or ſeven feet high. The leaves are narrower, and hollowed like the keel of a boat, and their tops hang downwards. The ſpikes of male flowers are ſhorter, and the ears of grain are ſlenderer, and not more than ſix or ſeven inches long. The grain does not come to maturity in England, unleſs the ſeaſon prove very warm, and it is ſown early in a warm ſoil and ſituation.

The third is cultivated in North America and Germany. The ſtalks are ſlender, and ſeldom riſe more than four feet high. The leaves are ſhorter and narrower than either of the former; they are hollowed like the keel of a boat, and their tops hang down. The ſpikes of male flowers are ſhort, and the ears of grain are ſeldom more than five or ſix inches long.

ZEA

This ripens its grain perfectly well in England, in as little time as Barley.

There are ſeveral varieties of the two laſt, differing in the colour of the grain. The moſt common colour is a yelloviſh white; but there are ſome with deep yellow, others with purple, and ſome with blue grains; and when the different colours are planted near each other, the farina will mix, and the ears will have grains of ſeveral colours intermixed on the ſame ſpike; but when the grains of the different varieties are planted at a proper diſtance from each other, the produce will be the ſame with the grains which were ſown. From long experience, ſays Mr. Miller, I can affirm, that theſe three are different, and do not alter by culture.

Maize is ſeldom cultivated in England for uſe; but in Italy, Germany, and North America it is the food of the poor inhabitants.

[We may add the South of France, Barbary, China, Cochinchina and Japan. It is much cultivated in the Weſt Indies: in Jamaica in all parts, among the young canes. The grain is reckoned a wholeſome hearty food, and is much uſed by the negroes, who make it into various meſſes. It is there given to horſes, and is the principal ſupport of poultry and ſmall ſtock, of which the people raiſe great quantities [t].

Mr. Miller thinks that Maize might be cultivated in England to advantage. But it can ſcarcely be expected to be grown here for the grain, except in favourable ſeaſons, and warm ſoils and ſituations. Yet as a fodder it might be of conſiderable ſervice, if it were cut when juſt opening into ear, and given freſh to the cattle every day.

This plant is an annual; native of America; and was cultivated here in 1562. As appears from Turner's herbal, part 2. fol. 58 [u].]

PROPAGATION AND CULTURE.

In North America it is treated in the following manner. They firſt dig the ground well in the ſpring, and having made it level, they draw a line croſs the whole piece; then they raiſe little hills at about three or four feet diſtance, into each of which they put two or three good ſeeds, covering them about an inch thick with earth. The rows are four feet aſunder, and the hills three or four feet diſtant from each other. Six quarts of ſeed is allowed to an acre, which, if the ſoil be good, will produce fifty buſhels of corn.

There is nothing more obſerved in the culture of this grain, but only to keep it clear from weeds, by frequent hoeing the ground; and when the ſtems are advanced, to draw the earth up in a hill about each plant, which, if done, will greatly ſtrengthen them, and preſerve the ground about their roots moiſt for a conſiderable time.

When the Corn is ripe they cut off the ſtalks cloſe to the ground, and after having gathered the ſpikes of grain, they ſpread the ſtalks in the ſun to harden and dry, which they afterward uſe in the ſame manner as Reeds in England for making fences, covering ſheds, &c. for which purpoſe they are very uſeful to the inhabitants of warm countries; and when there is a ſcarcity of forage, they feed their cattle with them green, as faſt as the Corn is gathered off.

The Corn is ground to flour, and the pooreſt ſort of people in America, and alſo in Italy and Germany, make their bread of this flour; and in many of the warmer countries, the inhabitants roaſt the whole ſpikes, and dreſs them many different ways, making ſeveral diſhes of them; but this grain ſeldom agrees with thoſe who have not been accuſtomed to eat it; however, in times of ſcarcity of other grain, this would be a better ſubſtitute for the poor than Bean flour, or other ſorts, which have been uſed in England; and at all times will be found a hearty food for cattle, hogs, and poultry; ſo that in light ſandy lands, where Beans ſucceed not well, this grain may be cultivated to anſwer both purpoſes to advantage.

If this grain is cultivated by the horſe-hoeing huſbandry, it may be done at leſs expenſe than in any other method; for this is one of the plants which is

[t] Brown. jam. 335.

[u] Hort. kew.

more

Digitized by Google

more particularly adapted to this huſbandry: therefore I ſhall here give an account of the method in which it has been cultivated by the horſe-hoe, and has ſucceeded beyond expectation.

The land was very light and ſandy, and far from being rich; this was ploughed deep before winter, and laid up in high ridges till the ſpring, when it was well harrowed to break it fine, and the beginning of april the ground was again ploughed, laid level, and well harrowed to make the ſurface ſmooth; then the ſeeds were ſown in drills, which were made four feet aſunder, into which the ſeeds were dropped at about a foot diſtance. When the plants were come up three inches high, where any of them were too cloſe, they were cut up with a hand hoe, and the intervals between the rows were ploughed ſhallow, to deſtroy the young weeds. But when the ſtems were advanced, the ground in the intervals was ploughed deeper, and the earth laid up to the plants on both ſides; and when the weeds began to grow again, the ground was a third time ploughed to deſtroy them; this kept the ground pretty clean from weeds till the grain was ripe, as the ſeaſon was not wet, but otherwiſe it would have required a fourth ploughing to anſwer this purpoſe. The ſtalks of theſe plants produced from three to ſix ſpikes of grain each, which was a great increaſe.

The time for ſowing this Corn, is about the ſame as for Barley; in light warm land it may be ſown the latter end of march or the beginning of april, but in cold ground, the middle or end of april will be early enough, for the grain is ſubject to rot in cold land, eſpecially if the ſeaſon proves wet. When the large ſorts are planted in a garden for curioſity, their ſeeds ſhould be ſown upon a moderate hot-bed the beginning of march; and when the plants are fit to remove, they ſhould be tranſplanted on another moderate hot-bed to bring them forward; but they muſt not be kept too cloſely covered, for that will draw them up weak; therefore, when the weather is mild, they ſhould be inured to bear the open air; and the beginning of may they ſhould be taken up with balls of earth to their roots, and tranſplanted into a warm border at three or four feet diſtance, carefully watering them if the weather proves dry, until they have taken new root, after which they will require no other care but to keep them clean from weeds. If the ſeaſon ſhould prove warm, theſe plants will ripen their grain in the autumn.

DESCRIPTIONS, &c.

1. This riſes to the height of four feet. The ſtalks become hard and woody, and divide into many branches. Leaves oblong, ſmooth, entire. Flowers terminating, ſolitary, with ſmaller leaves on the peduncle cloſe to the calyx. When blown they are as large as thoſe of the common Marygold, and of a yellow colour. They do not fall off, only changing

Digitized by Google

their colour, and adhere ſo cloſely to the ſeeds as to render it difficult to part them [x].

[Root annual. Stem round, erect, compound. Leaves ſmooth, three-nerved, quite entire, rugged at the edge. Calyx terminating, ſeſſile, ſolitary, ſmooth, cylindrical. Corolla yellow, permanent. Branches from the wings of the leaves, not next the flower, like the ſtem and higher [y].

Receptacle ovate-conical, covered below with the ſcales of the calyx, above with chaffs, hollow within. Chaffs oblong, keeled, longer than the ſeed. Seeds uniform, oblong, triangular or rhomb-compreſſed, ſtriated, pale. Down difform: of the ray none, but inſtead of it the ſhrivelled permanent female corolla; of the diſk awned: awns awl-ſhaped, ſpiny, ſtraight, unequal, ſingle or two together, very ſeldom three [z].

Native of Peru, whence the ſeeds were ſent to the Royal Garden at Paris. The plants produced ripe ſeeds there, ſome of which were ſent to Mr. Miller in 1753; and the following ſummer the plants flowered, and produced good ſeeds in the Chelſea garden [a].

In the ſeventh folio edition of the Dictionary it may be found under the name of Bidens; but both this and the ſecond ſpecies are omitted in the eighth edition. They are both in the fifth and ſixth quarto editions, under their proper name of Zinnia.]

2. Root annual. Stalk and branches more erect, cover d with ſoft hairs and channelled. Leaves three-nerved, hairy. Flowers terminating: ray of a deep gold-colour on the upper ſide when firſt open, but afterwards changing to a dark copper; on the outſide pale ſtraw-colour. Theſe are permanent like the former.

[Stem rough-haired. Leaves petioled. Ray of the corolla red [b]. It varies with the corolla red and yellow [c].

This differs from the former, to which it is ſo nearly allied as to be almoſt regarded as a variety, in being only about half the ſize; the ſtem round, not angular or grooved, but hirſute with very ſpreading hairs; the leaves more petioled; the flowers on long naked peduncles, in greater abundance, ſmaller, with a red (not yellow) ray; the calyx-ſcales oblong not orbicular. When in full flower, the corolla is purple powdered with gold, like Amaryllis formoſiſſima, and yellowiſh-green underneath: afterwards it becomes of a duller colour, red mixed with yellow, and green underneath. It is particular in having the florets of the diſk hirſute [d].

This ſpecies is deſcribed in detail by Jacquin, in his obſervations. The ray of the corolla is compoſed of from fifteen to thirty florets, of a deep ſhining ſcarlet above, and of a duſky yellowiſh colour beneath, both finally changing to brown. Chaffs in the diſk membranaceous, brown at the tip, converging ſo as to incloſe the whole floret laterally, except the border: ſeed-down has a ſingle awn oppoſite to the chaff. The radical florets have neither chaff nor down.

Native of North America. Miller and others ſay Louiſiana. The younger Linneus concludes it to be a native of Braſil, becauſe it came from France to Holland under the name of *Caithe de Breſil*, but that is probably erroneous. He ſays that ſeeds of it were firſt ſent to the botanic garden at Upſal by Nicol. Laur. Burman, M. D. and afterwards by Philip Miller, *horti Chelſeani Cuſtode, Hortulanorumque Principe.* Jacquin informs us, that ſeeds ſent to Vienna from Scheannitz in Hungary, and ſown in may, flowered from the end of july to november, and bore ripe ſeeds in october.

According to the Kew catalogue it was introduced about 1771. But Mr. Miller has deſcribed it, and given its culture in the fifth quarto edition of his Dictionary, publiſhed in 1763.

Mr. Curtis remarks, that there is a variety with yellow flowers, in our gardens, nearly as common as the red.

[x] Mill. fig. [y] Linn. ſpec. [z] Gærtner.
[a] Mill. fig. [b] Linn. ſyſt. [c] Willdenow.
[d] Linn. dec.

3. This reſembles the firſt ſpecies; but the leaves are always in whorls, three, four, or five together; and the ray of the corolla is red and double.

Native of Mexico [e].

4. Root annual. Stem erect, round, rough, ſix feet high, putting forth upright branches the whole length. Leaves acute, quite entire, rough on both ſides, appearing ciliate to the magnifier, veined, the larger ſeven-nerved and five inches long, the ſmaller five-nerved; the nerves rough-haired. Peduncles terminating, one-flowered, thickened at top, hollow, rough-haired, erect, from one to five inches long. Flowers handſome, but without ſcent. Calyxes at firſt ovate, but afterwards more bell-ſhaped; ſcales oblong, rounded, ſmooth, marked with lines, pale green with a dark edge, ciliate a little below. Corollets in the ray from twelve to twenty, emarginate or quite entire, more than an inch long, at firſt red above but afterwards violet, beneath of a dirty pale colour. Florets in the diſk yellow, villoſe within. Chaffs white, with a red top. Seeds obovate, flat, very ſhortly and equally two-pointed, brown.

Native of Mexico.

5. Root annual. Stem three feet high, erect, round, rugged, hirſute, branched, the thickneſs of a reed. Leaves acute, quite entire, rugged on both ſides, ſeſſile, appearing to the magnifier ciliate at the edges, three or five-nerved, hirſute on the nerves beneath, about two inches in length. Peduncles terminating, one-flowered, hirſute, thickened and fiſtular at the top, erect. Calyx cylindrical, about half an inch long; ſcales oblong, rounded, ſmooth, green with a dark edge. Corollets in the ray from eight to fifteen, quite entire or two-toothed, red-orange above, beneath dirty-pale. Florets in the diſk yellow within, duſky without. Germ three-ſided, hirſute, with an awn at one corner as long as the corollet, and at the two other corners a ſhort toothlet. Chaffs whitiſh with a ſooty tip [f].

To Jacquin's deſcription Mr. Curtis adds, that the florets of the ray are ſharp-pointed, very rough to the touch, and of a lively pale green underneath, not a dingy white, as he deſcribes them. Probably native of South America. Firſt raiſed here in the garden of Edward Woodford, Eſq. at Vauxhall, from ſeed ſent by Monſ. Thouin.]

[e] Willdenow. [f] Jacquin.

PROPAGATION AND CULTURE.

1. 2. Sow the ſeeds upon a moderate hot-bed in march. When the plants come up, raiſe the lights to give them air, whenever the weather is not too cold, otherwiſe the plants will draw up weak. When they are about an inch high, plant them on another hot-bed, but do not treat them too tenderly, for they are very ſubject to grow too luxuriant in branches. The firſt ſort will not produce many flowers, if the plants are not ſtinted in their growth while young, which may be effected by planting them in ſmall pots to confine their roots; otherwiſe the ſeeds will not ripen in England.

The ſecond ſort is much more prolific of flowers, and may be treated with leſs care. When the plants have been brought forward on the hotbed, inure them gradually to bear the open air in may, and in june tranſplant them into the borders of the flower-garden, where they will continue flowering all the ſummer, and will perfect their ſeeds very well: but the plants of the firſt ſort ſhould be placed in a ſtove or under a glaſs caſe, to obtain good ſeeds.

[3. 4. Sow the ſeeds on a hot-bed, as before, and about the end of may plant them in large pots or in the open border, where they will continue to flower till deſtroyed by the froſt.

5. Sow it on a common hot-bed with balſams and other tender annuals, and ſet out the plants in the open border at the end of may, where they will continue to flower for ſome months, and produce ripe ſeeds in favourable ſeaſons.

Panicle ſubracemed.

DESCRIPTIONS.

1. Root annual. Culm two feet high, obliquely erect, covered all over with the ſheaths of leaves. Branches two oppoſite, from the baſe of the culm, flower-bearing. Leaves five or ſix, even, wider than thoſe of the common Reed, with ſmooth ſheaths. Panicle below looſe and male, above ſpiked and female. Lower branches capillary, ſimply racemed, ſpreading horizontally, bearing two or three ſeſſile flowers. Spike terminating, erect, with the flowers ſubſeſſile, approximating to the rachis, female. Flowers deſcribed in the generic character. It is ſingular, that the inner valve involves the lateral margins, and the outer revolves them, and thus one embraces the other cloſely in the female flowers[g]. Seed oblong, roundiſh, a little narrower below, black or brown ruſt-colour, on one ſide convex with a ſtreak, on the other marked with a ſhallow groove[h].

Native of North America: in great abundance in the lakes of Canada. Mr. Lambert is perſuaded that it might be ſown with ſome advantage where no other grain will grow, in many ſhallow pieces of water in Great Britain and Ireland, eſpecially in the latter country, where there are many extenſive lakes which appear well ſuited for the purpoſe. In a pond at Spring grove, Sir Joſeph Banks has a great quantity of this plant, growing annually, ripening its ſeeds, and ſowing itſelf round the edges. The ſeeds for a long time were received from America, yet none of them grew. At length Dr. Nooth, by the deſire of Sir Joſeph Banks, ſent them from Canada, put up in jars of water. As ſoon as they arrived they were ſown in a proper ſituation, where they came up in a few days, and the plants ripened their ſeeds extremely well in the autumn. Theſe ſeeds, which are as large as oats, and perhaps as nutritive, are uſed by the Indians for food[k].

They have a pleaſant taſte, and make a pudding equal to Rice or Millet. Carver[l] ſays that this grain, which grows in great plenty throughout the interior parts of North America, is the moſt valuable of all the ſpontaneous productions of that country. Beſides its utility as a ſupply of food for the human ſpecies, obtained without any other trouble than that of gathering it in, it attracts an infinite number of wild fowl of various kinds, which become very fat and delicious by this rich repaſt. It might be of great ſervice to an infant colony, as it would afford a preſent ſupport without much labour, until by cultivation other ſupplies could be produced: firſt ſettlers, even in a temperate climate and on a good ſoil, being often expoſed to great hardſhips for want of an immediate ſupply of neceſſary food. This uſeful grain grows commonly where the water is about two feet deep, and where it finds a rich muddy ſoil. The ſtalks, which are full of joints, riſe more than eight feet above the water. Nearly about the time that the grain begins to turn from its milky ſtate and to ripen, the natives run their canoes into the midſt of it, and tying bunches of it together, juſt below the ears, with bark, leave it in this ſituation three or four weeks longer, until it is perfectly ripe. About the end of ſeptember they return, when each family having its ſeparate allotment, diſtinguiſhed by the manner of faſtening the ſheaves, gather in the portion that belongs to them.

As a ſubſtitute for Rice in our new ſettlements in the ſouthern hemiſphere, where the climate may be too cold for that grain, it ſhould ſeem to be a very deſirable acquiſition, and might be ſowed in the moraſſes and ſtagnated waters that always abound in thinly inhabited countries, and which require more labour to drain than new eſtabliſhments can afford[k].

The French in Canada call it *Folle Avoine*, the Engliſh, *Wild Rice*, and the Germans *Riſave*. What could induce Linneus, as Mr. White obſerves, to degrade this highly beneficial grain, with the name of that pernicious weed, which the enemy ſowed among the wheat, does not eaſily appear. He might not however be fully acquainted with its great utility, when he firſt impoſed the name upon it: and was perhaps influenced by its general reſemblance to that deſtructive weed the Wild Oat. The word *Zizania* not being found in any Greek author except St. Matthew, Mr. White deems it now impoſſible to aſcertain what plant the Evangeliſt intended. But ſurely a botaniſt who ſhould be in Paleſtine during the time that the Wheat crop was growing, might at leaſt make a ſhrewd gueſs at it. Haſſelquiſt has not made any mention of this weed.

Zizania paluſtris of Linneus's mantiſſa, is the ſame with what he had deſcribed in both editions of the Species Plantarum, under the name of Z. aquatica; as the original ſpecimen in his herbarium ſhews. It ſeems however that he latterly intended Sloane's plant, (hiſt. Jam. t. 67.) to remain as the *aquatica*; conceiving that, on account of its great ſpreading panicle, to be a different plant. Probably Browne's ſynonym belongs rather to Sloane's plant[l].

Sir Hans deſcribes it as putting forth roots from every joint, and ſending up round, hollow culms, jointed at every two inches diſtance, of a clay colour, and about the bigneſs of one's little finger. The ſheath of the leaf covers the whole internode; and the leaf is near half an inch broad at the baſe, tapers for more than a foot in length, and ends in a point of a blueiſh green colour. The ſtalks riſe fourteen or fifteen feet high; the top is a panicle of a foot in length, branched out into many rough ſpikes. He

Clinopodium ſupinum incanum. *Amm. ruth. n.* 66.

Flowers lateral, leaves ovate.]

DESCRIPTIONS, *&c.*

1. Root annual. Stem four-cornered, about four inches high, ſending out oppoſite ſide-branches from the bottom. Theſe are terminated by a cluſter of ſmall flowers ſurrounded by ovate leaves ending in acute points. Flowers purple, juſt emerging from the ſlender calyx.

[Seeds ovate, narrower towards the baſe, ſmooth, of a bay-ruſſet colour [n].

Flowers all terminating in bundles. Corolla without any ſpot on the palate, ſuch as may be ſeen in Z. tenuior [o]. From which this differs in having the flowers in a head, as the trivial name implies; and four ovate, acute bractes, ſurrounding the head [p].

Native of Syria, Armenia, Barbary, Siberia. Cultivated by Mr. Miller, in 1752 [q].] It flowers in june, july, and auguſt; and the ſeeds ripen about ſix weeks after.

[m] Linn. tranſ. vol. 7. [n] Gærtner. [o] Linn. mant. [p] Desfontaines. [q] Hort. kew.

2. Native of Spain.—Mr. Miller has a ſpecies under this name, which he ſays that he] received from Dr. Ruſſel, who procured the ſeeds from Aleppo. He deſcribes the flowers as diſpoſed in whorls; and the plant as ſmelling like Pennyroyal.

3. This ſends up many ſlender woody ſtalks, near a foot high. Leaves about the ſize of thoſe of Summer Savory, with a ſcent like them. Flowers in whorls, reſembling thoſe of the firſt ſort, and appearing at the ſame ſeaſon.

[Root annual. Plant branched, erect. Stems four-cornered, thickening above, pubeſcent. Leaves ciliate, toothletted or quite entire, running down into the petiole, with oblique nerves beneath. Flowers whorled, ſpiked; each pedicelled. Tube of the corolla a little longer than the calyx. Bractes lanceolate, oppoſite, longer than the flowers. Two of the ſtamens are fertile, and two barren [r]. Native of the Levant and Barbary.—Cultivated in 1752, by Mr. Miller. It flowers in june and july [s].

4. This has the habit of Thymus Acinos; but all the parts are five times as big. It has the leaves of the firſt ſpecies, and lateral flowers as in the third, but more abundant. The calyxes are hiſpid as in that; and the ſtamens thruſt out beyond the tube of the corolla. Native of Siberia [t]. Introduced in 1786, by William Pitcairn, M. D. It flowers in july and auguſt; and is perennial [u].]

PROPAGATION AND CULTURE.

Sow the ſeeds in a border of light earth, where they are to remain, either in ſpring or autumn. Thoſe plants which come up in autumn will abide through the winter, and grow much larger than thoſe which come up in the ſpring: their ſeeds will be ripe in july or auguſt; but thoſe of the ſpring plants will not ripen till the end of auguſt, or the beginning of ſeptember; when, if the ſeeds are permitted to ſcatter, the plants will come up, and require no farther care but to clear them from weeds, and thin them where they are too cloſe.

Zoegea

Digitized by Google

Zoegea aleppica. *Jacqu. ic.* 1. *t.* 177. *collect.* 1. 89.

DESCRIPTION, *&c.*

This is an annual plant, with the ſtem branched, almoſt upright, round, ſcarcely ſtriated, ſquallid, about eighteen inches in height, ſcarcely as thick as a reed. Branches and branchlets alternate, diffuſed, angular, ſtriated, ſomewhat rugged. Leaves alternate, petioled, ſpreading. The radical and lower ſtem leaves pinnatifid, with two or three pairs of ſegments, which are moſtly oppoſite, remote, ovate or oblong, one-nerved, bluntiſh or ſharply acuminate, (the lower ones gradually leſs, the outmoſt very large, lanceolate, ſomewhat toothed;) villoſe, ſquallid, ſomewhat rugged, pale, three inches long, and two wide. The branch-leaves ſubſeſſile, lanceolate, bluntiſh with a ſharp point, almoſt entire, three-nerved, reclining, gradually leſs to the tip. Petioles widiſh, keeled, running into the leaf, widened at the baſe, much ſhorter than the leaf, very ſhort even on the branch-leaves. Flowers terminating, ſolitary, erect, yellow, on elongated peduncles, which are thickened at the top, ſtriated, ſquallid, bracted or naked, two inches in length. Bracte (when there is one) towards the middle of the peduncle, ſeſſile, linear, ciliate at the tip; and ſome of the ſame ſhape now and then ſcattered at the apex of the peduncle [x].

Linneus deſcribes the ſtem as a palm only in height; the leaves ſeſſile, remote, quite entire and rugged; the peduncles naked and one-flowered; the flowers like thoſe in the genus Centaurea, with a ciliate calyx, the ciliæ teſtaceous; and the corolla like that of Calendula or Marygold, of a fulvous or tawny yellow colour. He refers to a ſpecies of Centaurea in Gmelin's Itin. 1. 126. t. 20. as being perhaps the ſame with this [y].

It was found by Andr. Michaux, in the Levant, and is rather a handſome plant, flowering in ſummer and autumn, and ripening a few ſeeds [z].

ZOOPHTHALMUM. See *Dolichos.*

δ. Potamogeiton marinum in utriculis epiphylloſpermon minus. *Raii ſyn.* 53.

ε. Alga anguſtifolia vitrariorum. *Raii ſyn.* 53.

DESCRIPTION, &c.

Root fibrous, ſeemingly perennial, throwing out roots from the joints of its long, round, ſmooth, branching ſtem; which at the baſe is decumbent, but above floating, leafy, and compreſſed a little. Leaves alternate, petioled, very long, linear, flaccid and tender, bluntiſh, quite entire, ſmooth, a little above the baſe opening by a longitudinal fiſſure, and putting forth a flat, linear ſpadix, bearing flowers on one ſide. The flowers are completely protected from the ſalt water, under which they grow, by this ſheathing baſe of the leaf, which cloſely enfolds them.

Linneus placed this genus in the claſs Gynandria, conſidering its ſpadix as the common receptacle of one flower, compoſed of many anthers, ranged alternately with many piſtils. Thunberg and Withering, aboliſhing that claſs, have referred it to Polyandria Polygynia. The flowers are by no means gynandrous, as the ſtamens cannot in any ſenſe be underſtood to grow out of the piſtils; neither are they ſimply polyandrous, as in every ſuch flower, the male organs are invariably collected round the central females. Nor will the analogy of Arum, however we may underſtand that flower, at all help us to comprehend this, they having no real affinity. Zoſtera is eaſier underſtood as a ſimple unilateral ſpike of naked flowers diſpoſed in two ranks. The anther of each is ſeſſile, oblong, a little curved. By its ſide is affixed an oblong germ, with a ſhort ſtyle, having two long linear pointed ſtigmas. Theſe are arranged along the ſpike alternately, ſo that each anther may perhaps impregnate the germ of the flower below it.

Native of the ſea coaſt, in æſtuaries and ſalt water ditches, as about Yarmouth; flowering in auguſt and ſeptember [a].

It is thrown on the ſhore by the tide in great plenty, and mounds are made with it to oppoſe the encroachment of the ſea. Buildings are thatched with the green leaves, and this covering will endure upwards of a century. Expoſure to the weather bleacheſ it white. It is uſed by the inhabitants of Gothland as a manure, and alſo for ſtuffing beds in preference to hay, as being ſofter. Horſes and ſwine eat it. Cows are not fond of it [b].

Dr. Smith has reduced Ray's varieties to one ſpecies, till experience ſhall have informed us better; he has alſo collated the inedited figures of Micheli, in his own and Sir Joſeph Banks's libraries.—Zoſtera oceanica of Linneus, a plant of a peculiar genus, is not found on our ſhores. The fructification of it has been illuſtrated by Filippo Cavolini, in Uſteri annal. bot. faſc. 9. and by Micheli in ic. ined. t. 58 [c].

Cal. five-parted. *Pet.* five. *Filam.* widened at the baſe, hairy. *Capſ.* five, coriaceous, one-ſeeded, inſerted into a fleſhy receptacle.

SPECIES.

1. Zwingera amara.
Willd. ſpec. 2. 569.
Simaba guianenſis. *Aubl. guian.* 1. 400. *t.* 153.

DESCRIPTION, *&c.*

This is a ſhrub, about eight feet in height. Leaves alternate, unequally pinnate, of five leaflets, or elſe ternate. Leaflets oblong, acuminate, emarginate, quite entire, veined, ſmooth. Peduncles three-flowered, axillary. Flowers white.

The genus approaches very near to that of Quaſſia; but differs in having a five-parted (not a five-leaved) calyx; in not having any nectary; and in the fruits being dry. It admits of doubt however whether this be a ſufficient character to make a diſtinct genus; Quaſſia excelſa having no nectary.

Native of Guiana, in woods[a].

Leaves pinnate, ſtem arboreous.

DESCRIPTIONS, &c.

1. This is a tender ſucculent, which came up from ſeeds ſent by Forſkahl, but did not flower. Stem herbaceous, dichotomous, divaricating. Leaves oppoſite, ſubſeſſile, fleſhy, linear, ſpreading very much. Flowers yellow.

Digitized by Google

Native of Arabia [a].

2. Found at the Cape of Good Hope by Thunberg [c]. Introduced in 1774, by Mr. Fr. Maſſon. It flowers here in October [g].]

3. Root thick, fleſhy, ſtriking deep into the ground. The ſtalks decay every autumn to the root, from which ſpring new ſhoots every year, in number proportionable to the ſize of the root: they riſe three or four feet high, and ſend out a few ſmooth, green, jointed branches. Leaves ſmooth, fleſhy like thoſe of Purſlane, two together on the ſame foot-ſtalk, which is an inch long; they are of a bluiſh green colour. Flowers axillary, two or three from the ſame joint, on ſhort peduncles. Petals roundiſh, concave, of a reddiſh colour on the outſide. [Capſule, before it is full ripe, ſubcylindrical, ſmooth, filled with a ſoft pulp; afterwards columnar-oblong, juiceleſs, ſharply five-cornered, where the ſeeds are repand-knobbed. Seeds about ten in each cell, irregularly ovate, ſomewhat kidney-ſhaped and flexuoſe, compreſſed greeniſh or dirty ruſſet, faſtened to the central margin of the partitions, in a double row in each cell [b].

Native of Syria and Siberia.—Cultivated in 1596, by Gerarde. It flowers in july [i].

4. This ſpecies comes neareſt to *Zyg. Morgſana*, but the leaves of that are fleſhy, nearly ſeſſile, and ſcentleſs; theſe are not fleſhy, ſtand on long footſtalks, and diffuſe widely a ſtrong foxy ſmell, like that of Crown Imperial; the flowers of that are ſmall, of this large and ornamental, when the plant is healthy; the ſeed-veſſel of the *Morgſana* has four wings, but in this there is not the leaſt appearance of any. Native of the Cape of Good Hope. It flowers from july to ſeptember [k].—Petals yellow, with duſky red ſpots near the baſe. The fruiting peduncle turns back, whence Thunberg's trivial name *retrofractum*.

5. Petals yellow, with a red heart-ſhaped ſpot at the baſe of each, and above that a tranſverſe red line in the three upper petals. Native of the Cape of Good Hope. Introduced in 1782, by George Wynch, Eſq. It flowers in november [l].

6. This is diſtinguiſhed from the next ſpecies, by having ſcarlet flowers, and oblong capſules. Native of Africa and Siberia [m].

7. This is a ſmall ſucculent hoary ſhrub. Leaves oppoſite, ovate, round. Petiole ovate-oblong, ſtill bigger. Peduncles lateral, one-flowered, very ſhort. Calyx purpliſh, concave. Petals broad-lanceolate. At the baſe of the ſtamens ſcales, covering the receptacle. Receptacle of the fruit fleſhy, bigger than the germ, depreſſed, with ten obſcure angles. Germ ſuperior, ovate. Style with five acute ſtigmas [n].

Stem knobbed, ſuffruticoſe, procumbent, very much branched. Leaves fleſhy, ſhort, obtuſe, ſometimes ſimple, ſometimes conjugate. Flowers axillary, ſolitary, ſeſſile. Calyx five-parted. Corolla white, longer than the calyx [o].

Native of Egypt; of Barbary, in the ſands of the deſert, and on the coaſt; and of the Canary iſlands, whence it was introduced by Maſſon in 1779 [p]. The younger Linneus informs us, that the ſeeds were ſent to Sweden from Egypt by Dr. Roquè, in 1760.]

8. Stem ſhrubby, divided into many irregular jointed branches, and riſing four or ſix feet high. Leaves thick, ſucculent, larger and more obtuſe than thoſe of the tenth ſort, and placed by fours at each joint, two on each ſide the ſtalk oppoſite. Flowers axillary upon ſlender foot-ſtalks; they have but four petals, which are broader than thoſe of the tenth ſort, but of the ſame colour, each having a brown ſpot at their tails. The fruit has four broad membranaceous wings, reſembling the ſails of a mill.

[Stem round, jointed, aſh-coloured; with alternate branches. Leaves oppoſite, ſubſeſſile: leaflets obtuſe, quite entire, fleſhy, even. Stipules ſolitary between the petioles, linear, reflexed. Peduncles lateral, two together, one-flowered, interfoliaceous.

[a] Linn. mant. [b] Gærtner. [c] Hort. kew. [g] Hort. kew. [i] Hort. kew. [k] Curtis. [l] Hort. kew. [m] Linn. ſpec. [n] Linn. mant. [o] Desfontaines. [p] Hort. kew.

Calyx four-leaved, even, concave, obtuſe. Corolla yellow, within the tips of the calyx brown. Petals four, ſometimes but ſeldom five, ſpreading; ſlightly emarginate. Stamens double the number of the petals, erect. Anthers yellow, with a yellow nectareous ſcale at the baſe, brown at the edge. Style length of the ſtamens [s].

Native of the Cape of Good Hope. Cultivated in 1732, by James Sherard, M. D. It flowers moſt part of the ſummer [r].

9. Stem ſhrubby, upright, with the branches for the moſt part alternate. Leaves oppoſite, ſubpetioled, conjugate; leaflets ſomewhat fleſhy, flat. Peduncles capillary, lateral, length of the leaves, ſolitary. Petals oblong, yellow. Capſule retuſe at both ends, five-cornered; with the corners very much compreſſed, and rounded. Found by Thunberg at the Cape of Good Hope [t].

10. Leaves ſeſſile: leaflets cartilaginous crenate or rugged at the edge. Stem angular. Peduncles ſolitary, longer than the leaves. Petals crenate [u].]

α. Stem thick, woody, three or four feet high, ſending out many branches. Leaves ſucculent, ſeſſile, placed by fours. Peduncles axillary, long, ſlender. Petals five, ſulphur-coloured, with a brown ſpot on the tail of each. Capſule roundiſh, depreſſed, five-celled: each cell containing two roundiſh ſeeds.

β. Stems ſhrubby, jointed, irregular, branching out greatly from the bottom. Leaves the conſiſtence of Purſlane, narrow at their tails, but ovate towards their points, placed by fours at each joint. Flowers axillary, upon ſlender peduncles. Petals pale yellow, with a pretty large red ſpot at the tail of each. Capſule ovate, about three quarters of an inch long, having five deep furrows, and divided into five cells, filled with roundiſh ſeeds. They both flower great part of the year, and the fruit ripens at the end of autumn or in winter.

[The chief difference in theſe conſiſts in the ſhape of the fruit. Native of the Cape of Good Hope. Cultivated in 1713, by the Dutcheſs Dowager of Beaufort [x].

11. Stem erect, with alternate branches the length of the plant. Stipules four in whorls, awl-ſhaped, very ſhort, ſtiffiſh. Leaves in fours, linear, fleſhy, flat above, beneath roundiſh, acute. Corollas nodding, yellow [x]. Native of the Cape of Good Hope.

12. Stems herbaceous, a foot high, even, diffuſed, roundiſh, flat on the upper ſide. Stipules in fives, reflexed; two between the leaves at the upper ſide, one between the leaves at the lower ſide, and one between each pair of leaves. Found in Surinam by Rolander [y].

13. This plant is of a doubtful gender. The ſtem ſeems to be herbaceous, flexuoſe, round, ſmooth, but very woolly at the joints. Leaves oppoſite, petioled, ternate, ſmall. Leaflets on very ſhort petioles, roundiſh, attenuated at the baſe, mucronate at the tip, on the upper ſurface even, on the lower covered with raiſed papillæ. Peduncles axillary, ſolitary, one-flowered, erect in flowering-time, but afterwards drooping. Calyx five-leaved: leaflets linear, obtuſe, pubeſcent within and at the edge. Corolla, if any, was fallen off. Filaments a little dilated at the baſe. Germ club-ſhaped. Styles five, long, filiform. Stigmas [z] blunt. Capſule five-cornered, ovate, five-celled, five-valved opening at the baſe; valves keel-edged. Seeds ſolitary. Native of Sierra Leone [z].

14. This is a very handſome tree, forty feet high, with a very thick large elegant head. Trunk upright, dividing into numerous oppoſite or dichotomous branches. Leaves pinnate, ſhining, oppoſite, very numerous; the midrib three inches long, and abrupt; leaflets on each ſide ſix or ſeven, oblong, quite entire, obtuſe, ſeſſile, alternate. Racemes looſe, oppoſite, often dichotomous, axillary and terminating. Flowers inodorous, large, handſome. Calyx yelloviſh-green. Petals orange, roundiſh, with a claw the length of the cal-

calyx. Scales of the nectary hirſute, in the upper filaments gradually larger, in the uppermoſt very large. Stamens converging. Germ attenuated at the baſe into a long thick five-grooved pedicel. Capſule with five very large membranaceous wings. This tree has a very beautiful appearance when in flower. The natives call it *Guayacan*, but they give that name to all hard woods. They have a notion that if it be buried in the ground, it will be converted into ſtone.

Native of Carthagena in Spaniſh America, in woody vallies; and common in ſandy woods on the coaſt: flowering in july *.]

PROPAGATION AND CULTURE.

The third ſort is only propagated by ſeeds, which ripen very well in England in warm ſeaſons; theſe may be either ſown upon a moderate hot-bed in the ſpring, or on a warm border of light ground; thoſe which are ſown upon the hot-bed will come up in three weeks or a month, and about a month after, the plants will be fit to remove, when they ſhould be each planted in a ſeparate ſmall pot filled with freſh light earth, and plunged into a gentle hot-bed to promote their taking root, and ſhaded from the ſun in the day time; afterward they muſt be gradually hardened to bear the open air, to which they ſhould be expoſed all the ſummer; but in autumn, when their ſtalks begin to decay, they ſhould be placed in a hot-bed frame to ſhelter them from the froſt in winter, for while they are young, they are a little tender. The ſpring following they may be turned out of the pots, and planted in a ſouth border cloſe to the wall, in a dry rubbiſhy ſoil, where they will endure the cold without covering. There is a plant of this kind in the Chelſea Garden, which is more than fifty years old, and has reſiſted the ſevereſt cold without any covering, and produces great plenty of flowers and fruit annually. Thoſe plants which come up in the full ground will require no other care but to keep them clean from weeds, and thin them where they come up too cloſe, giving them room to grow the firſt year; and when their ſtalks decay in autumn, the ſurface of the ground

* Jacquin.

ſhould be covered with tan to prevent the froſt from penetrating to the roots, or in froſty weather, they may be covered with ſtraw or Peas haulm, which will anſwer the ſame purpoſe, the young plants being ſomewhat tender; and in the ſpring, the roots ſhould be carefully taken up, planting them cloſe to a warm wall, as before directed.

The other ſorts are too tender to live through the winter in the open air in this country, ſo they muſt be kept in pots, and houſed in autumn. Theſe plants may be propagated either by ſeeds or cuttings.

The tenth ſort ripens its ſeeds pretty well in England, and may be propagated by ſowing them on a moderate hot-bed in the ſpring; when the plants are about an inch high, they ſhould be each tranſplanted into a ſmall pot filled with light earth, and plunged into a moderate hot-bed, ſhading them from the ſun till they have taken root; then as the ſeaſon advances, they ſhould be gradually hardened to bear the open air, into which they ſhould be removed the latter end of may, placing them in a warm ſheltered ſituation, where they may remain till autumn, when they ſhould be placed in a dry airy glaſs-caſe, where they will ſucceed better than in a green-houſe; for they require a large ſhare of air in mild weather, otherwiſe their ſhoots are apt to be weak and tender, ſo are often injured by damp air in winter, but they do not require any artificial heat. If they are ſcreened from the froſt, and have plenty of air, they will thrive very well.

The eighth ſort ſeldom produces good ſeeds in England, ſo is propagated by cuttings, and the tenth is generally increaſed in the gardens the ſame way, that method being very expeditious, though the ſeedling plants grow ſtronger, and riſe to a greater height. Theſe cuttings may be planted in a bed of light earth during any of the ſummer months; if theſe are covered cloſe down with bell or hand-glaſſes, and ſhaded from the ſun, they will put out roots in five or ſix weeks, and then may be taken up carefully and potted, placing them in the ſhade till they have taken new root; after which they may be removed to a warm ſheltered ſituation, and treated in the ſame way as thoſe plants raiſed from ſeeds.
